Effects produced by an increase in the calcium and phosphorus content of the diet on the calcium and phosphorus balance and on various bodily constituents of the rat. John Haldi, Geo. Bachmann, Winfrey Wynn and Charles Ensor. *J. Nutrition* **18**, 399–409(1939).—When large amts. of Ca and P were added to the rations nearly all the excess Ca was recovered in the feces, while the P in the feces was considerably less than the excess intake. A little of the excess of absorbed Ca was stored in the body; none of the P was so stored. The percentage gain in body wt. was not affected by the high Ca and P intake; however, the body dry wt. was lower. The body fat content was reduced by the increased intake of Ca and P. The diminution in the total fat and dry wt. was approx. the same. Both the fat and dry wt. of the body showed a progressive decline with a progressive increase in the Ca and P intake. C. R. Fellers

Simultaneous appearance of a positive line test and radioactive phosphate deposition in the rachitic rat metaphysis. Kenneth Morgareidge and Marian LeFevre Manly. *J. Nutrition* **18**, 411–21(1939).—After a single dose of Na_2HPO_4 contg. the radioactive isotope (P^{32}) accompanied by a single dose of vitamin D_2, detns. were made of the radioactive P of the whole blood and of the tibial diaphysis and metaphysis of rachitic rats. Vitamin D has no influence on the entrance of P into the blood or

into the diaphyseal portion of the tibia. In the metaphysis the healing produced by vitamin D occurs concomitantly with a significant increase in the content of radioactive P. These effects in the metaphysis are seen only after an elapse of 54–72 hrs. subsequent to the administration of the vitamin D. These results support the conclusion that the mode of action of vitamin D is not limited to the control of intestinal absorption of the elements concerned in calcification. C. R. Fellers

Effect of heat and solvents on the nutritive value of soybean protein. L. Margaret Johnson, Helen T. Parsons and Harry Steenbock. *J. Nutrition* **18**, 423–34(1939).—S and N balances on rats showed that the nutritive value of soybean protein is improved by heat. The claim that treatment with certain solvents such as hexane and MeOH have a similar effect was not substantiated. Soybeans contain a S- and N-contg. complex which is absorbable but cannot be used for tissue-building purposes. Heating the soybeans makes it available. 25 references. C. R. Fellers

Pathology of B_6 deficiency in the rat and response to treatment with 2-methyl-3-hydroxy-4,5-dihydroxymethylpyridine (synthetic vitamin B_6). Wm. Antopol and Klaus Unna. *Proc. Soc. Exptl. Biol. Med.* **42**, 126–7(1939).—The skin lesions resulting from lack of vitamin B_6 are described. They were promptly cured by a single dose of 100 γ of synthetic B_6. L. E. Gilson

Effects of vitamin C deficiency and diphtheria toxin on cellular blood constituents of the guinea pig. Alex Sigal. *Proc. Soc. Exptl. Biol. Med.* **42**, 163–7(1939).—Accompanying the anemia of scurvy there was a progressive decrease in hemoglobin and erythrocytes and a slight increase in leucocytes. Guinea pigs receiving 3 mg. vitamin C per day and given subcutaneous injections of diphtheria toxin showed less disturbance in their blood cell count than similarly injected animals receiving 0.5 mg. or less of the vitamin per day. The changes in the latter group were characterized by chromatophilia, anisocytosis and poikilocytosis. L. E. Gilson

Vitamin B_6 deficiency in chicks. Thomas H. Jukes. *Proc. Soc. Exptl. Biol. Med.* **42**, 180–2(1939).—The symptoms of vitamin B_6 deficiency in chicks are slow growth, depressed appetite and inefficient utilization of food, followed in some cases by spasmodic convulsions and death. These are prevented by the addn. of 0.3 mg. synthetic B_6 to 100 g. of diet. A suitable diet for such studies is described. L. E. Gilson

Nutritional achromotrichia. J. J. Oleson, C. A. Elvehjem and E. B. Hart. *Proc. Soc. Exptl. Biol. Med.* **42**, 283–5(1939).—The dietary factor which prevents nutritional achromotrichia (defective hair pigmentation) in colored rats is present in liver ext. It is distinct from pantothenic acid, factor W, and all factors of the vitamin B complex thus far identified and assocd. with any specific function in the nutrition of rats. L. E. Gilson

Phenanthrene in relation to growth of rats maintained on a low-casein diet. Jakob A. Stekol. *Proc. Soc. Exptl. Biol. Med.* **42**, 328–30(1939).—Phenanthrene was fed at the rate of 0.5 g per 100 g. diet to growing rats on a low-casein diet. Growth ceased, but was resumed when *l*-cystine or *dl*-methionine was added to the diet. Taurine did not bring about a resumption of growth. It is assumed that phenanthrene is detoxicated in the rat to yield a mercapturic acid, and this detoxication takes precedence over the needs of the animal for growth purposes. L. E. Gilson

Vitamin B_1 content and antineuritic properties. I. Studies on sunflower seeds. Luigi Callegari. *Boll. soc. ital. biol. sper.* **14**, 484–6(1939).—Sunflower seeds contained 3.40 γ (1.7 international units) vitamin B_1 by chem. test. Comparative biol. tests with pure vitamin B_1 showed that all the vitamin in the seeds was not available when they were ingested. **II. Studies on the fruit of Rosa canina.** *Ibid.* 486–7.—The vitamin B_1 content of the dried fruit was 1.2 γ per g. The addn. of *Rosa canina* to a deficient diet caused no protection against avitaminosis B_1. Helen Lee Gruehl

Changing concepts of deficiency diseases. V. P. Sydenstricker. *J. Med. Assoc. Alabama* **9**, 105–9(1939).—This review, with 11 references, emphasizes the endogenous factors which may contribute to vitamin-deficiency diseases. E. J. C.

The use of vitamins in eye, ear, nose and throat practice. Ralph M. Clements and Harvey B. Searcy. *J. Med. Assoc. Alabama* **9**, 109–13(1939).—A review with 20 references and a summary of original experience of C. and S. E. J. C.

The protein problem in the efficient feeding of hens. Arthur Rdatz. *Kuhn-Arch.* **49**, 389–94(1938).—A protein ratio in the feed of 1.5 results in the best egg production. Animal protein (fish and meat meal) appears to be more efficient than plant protein (bean). C. K. H.

Acetonemia—observations on clinical and nonclinical cases. J. F. Bullard. *Cornell Vet.* **29**, 377–83(1939).—In tests made on 589 samples of urine taken during a 60-day period from a herd of 55 dairy cows, 1 or more pos. reactions for ketones were obtained on 31 animals but only 6 showed visible clinical symptoms of acetonemia. Cows that received a ration contg. as much as 50% soybeans in combination with corn and oats showed less evidence of acetonemia than did those fed much smaller amts. of soybeans, but there was a noticeable increase in the incidence of acetonemia when the corn was left out of the ration. K. D. Jacob

The significance of amino acids in nutrition. J. S. C. Marais. *J. S. African Vet. Med. Assoc.* **10**, 23–8(1939).—A review of recent investigations, with 22 references. K. D. Jacob

The stability of vitamin A from cod-liver oil in mixed feeds. R. C. Holder and S. K. Ford. *Poultry Sci.* **18**, 345–9(1939).—Cod-liver oil was added to a vitamin A-deficient ration at varying levels and the mixed feed was stored for 60 days in burlap bags at 70–80°F. in a well-ventilated room. On 8-week tests with chicks no loss of vitamin A was detected, but there was an indication of a slight loss from the stored feed when the test was continued for 10 weeks. K. D. Jacob

The importance of riboflavin in reproduction in poultry. A. E. Schumacher and G. F. Heuser. *Poultry Sci.* **18**, 369–74(1939).—Hatchability was influenced within a very short time (frequently in 1 week or earlier) by changes in the riboflavin content of the ration. With hens that received rations contg. 230 γ riboflavin per 100 g. feed, an addnl. oral supplement daily of 100 γ cryst. riboflavin for 4 weeks caused only small improvement in hatchability; greater improvement was obtained when the ration contained smaller amts. of riboflavin. Birds with the lower initial hatchability within a lot showed greater relative improvement, but a small no. of hens which gave no hatchability during the entire period showed no improvement even when the supplemental feeding of riboflavin was increased to 200 γ daily. Riboflavin injection of hens and eggs had no effect on hatchability. K. D. Jacob

The stability of vitamins A and D in mixed feed ingredients. II. Vitamin A. F. D. Baird, A. T. Ringrose and M. J. MacMillan. *Poultry Sci.* **18**, 441–8(1939); cf. *C. A.* **33**, 2946⁷.—Vitamin A from fortified cod-liver oil, when mixed in the ration to provide 100–300 units per 100 g., was not completely destroyed when the feed was stored in burlap bags at summer temps. for 25 weeks, although it underwent progressive destruction as the storage period advanced. When it was incorporated in the ration fresh weekly, 150 units vitamin A from fortified cod-liver oil was sufficient to meet chicks' requirements, but 200 units per 100 g. ration fed after storage for 8 weeks was insufficient. Incorporation of 300 units vitamin A in 100 g. of ration that was subsequently stored for 21 weeks at summer temps. provided sufficient vitamin for practically normal growth and prevented outward symptoms of deficiency in chicks to 8 weeks of age, though the amt. of urates in the kidneys increased at and after 12 weeks' storage. K. D. J.

A method for determining the gross value of protein concentrates [for chickens]. Victor Heiman, J. S. Carver and J. W. Cook. *Poultry Sci.* **18**, 464–74(1939).

—The chicks are first subjected to a depletion period on a diet contg. 8% protein from cereal sources (except for the vitamin G complex supplement). They are then standardized as to body wt. and duplicate groups are given an exptl. diet contg. 3% protein from the supplement. The increase in body wt. of chicks on the exptl. diet over that of chicks on the neg. control diet is used as a measure of the gross protein value. Compared to casein as 100, the gross protein values of soybean meal (Manchurian hydraulic press), herring meal, dried skim-milk, alfalfa leaves (10-in. plants), alfalfa leaves (24-in. plants) and alfalfa hay (10-in. plants) were 56.3–58.5, 93–105, 88, 13, 5 and 14, resp. K. D. Jacob

The utilization of simple nitrogenous compounds such as urea and ammonium bicarbonate by growing calves. E. B. Hart, G. Bohstedt, H. J. Deobald and M. I. Wegner. *J. Dairy Sci.* **22**, 785–98(1939); cf. *C. A.* **33**, 5896⁴.—Expts. involving the utilization of urea and NH_4HCO_3 nitrogen with 10 growing calves are described. It is indicated that such N can be used for at least a partial supply of protein N. The most probable explanation is the production of protein by bacterial cell multiplication in the rumen and later digestion in the fourth stomach and intestine. Apparently most efficient utilization occurs when some sol. sugar such as corn molasses is fed in the ration. With urea N constituting 43% of the N ration the growth rate was but slightly less than that secured with a ration contg. 66% of its N as casein N. This does not imply that urea N in the ration used was superior to casein N. When casein N constituted 43% of the total N of the ration, the growth rate over a period of 16 weeks was 1.5 lb. daily compared with 1.3 lb. daily for the comparable level of urea N. The N of NH_4HCO_3 was also utilized. Analysis of the tissues at the end of the expt. indicated that the increments in wt. with urea or NH_4HCO_3 nitrogen were of normal compn. with a protein content similar to that of the casein-fed animal.
A. H. Johnson

Carotene intake, level of blood-plasma carotene, and the development of papillary edema and nyctalopia in calves. L. A. Moore. *J. Dairy Sci.* **22**, 803–12(1939).—Calves placed on low carotene rations at 40 to 90 days of age developed nyctalopia in 48–73 days. Papillary edema developed at approx. the same time although there were some variations. An intake of about 9 γ of carotene per lb. of body wt. was not sufficient to prevent nyctalopia or an increase in papillary edema. An intake of about 16 γ per lb. of body wt. was sufficient to maintain the plasma carotene at 0.2 γ per cc. and above in Holstein and Ayrshire calves and was sufficient to prevent nyctalopia and maintain fair general health. When the plasma carotene fell below about 0.13 γ per cc. nyctalopia and papillary edema followed. The carotene requirements of Guilbert and Hart for the bovine animal are approx. correct when nyctalopia is used as the criterion.
A. H. Johnson

The influence of nutrition upon the formation of inheritable mutations. H. Stubbe. *Angew. Chem.* **52**, 599–602(1939).—Exptl. results are described on the effect of variations in nutrition upon *Antirrhinum majus* both by soilless growth and soil culture. The increase in mutation rate is not detd. so much by deficiencies in nutrition as by the disturbances in the food metabolism. Short-wave radiation (x-ray) also affects the mutation rate. 17 references. Karl Kammermeyer

A preliminary note on defective tooth structure in young albino rats as a result of vitamin A deficiency in the maternal diet. Helen Mellanby. *Brit. Dental J.* **67**, 187–94(1939).—Young albino rats born of mothers who had received a diet deficient in vitamin A for 5–7 months showed (1) degenerated enamel organs of the incisors and molars, (2) poorly calcified dentine, (3) groups of ossifying cells in the pulp and (4) abnormal mandible.
Frances Krasnow

Nutrition and disease. J. C. Spence. *Brit. Dental J.* **67**, 329–40(1939).—Coördinated clinical observations and controlled lab. expts. are necessary for studying nutrition in its relation to dental disease. Data assembled should consist of serial examns., seasonal variation in incidence of caries, correlation of bodily growth with dental structure and caries, influence of preceding diseases on dental diseases and influence of endocrine glands on teeth.
Frances Krasnow

Carbohydrate metabolism in kidney pulp. Amandus Hahn and H. Gerstenberger. *Z. Biol.* **99**, 618–23(1939).—Results show that (1) formation of lactic acid from glycogen is trifling in liver pulp and absent in kidney pulp; (2) diastatic decompn. of glycogen occurs in liver pulp, but not in muscle or kidney pulp; (3) cleavage of glyceric acid-phosphoric acid into pyruvic and phosphoric acids takes place readily in muscle pulp, but only slightly in liver and kidney pulp; (4) in muscle, liver and kidney pulp, addn. of glycerophosphoric acid together with pyruvic acid causes lactic acid formation through dismutation; (5) production of lactic acid from glucose was observed only in kidney pulp and was not influenced by O_2 while production of lactic acid from glycogen in muscle pulp was checked or entirely inhibited by O_2 and (6) in liver pulp production of lactic acid from hexose diphosphate is minimal while in kidney pulp it takes place to a greater extent, the process not being influenced by O_2.
Frances Krasnow

A review on vitamin B_1 (aneurin). Valentin Fürst, Jr. *Tids. Norske Laegeforen.* **59**, 667–85(1939). H. K.

The preventive action of paraffin oils in the utilization of vitamin A-active substances. Torben K. With. *Nord. Med.* **3**, 2468–70(1939).—Expts. on rats with vitamin A or carotene dissolved in paraffin oil and the same dose of vitamin A in a saponifiable oil show that the utilization of carotene in paraffin oil was reduced about $^1/_{40}$ to $^1/_5$, of vitamin A to about $^1/_2$. H. Kringstad

B avitaminosis. Ruth Wegelius. *Nord. Med.* **4**, 3208–10(1939).—A case of beriberi and pellagra is described. By treatment with a B vitamin prepn. (Ido-B-Granulate) the patient recovered. After 3 weeks a new outbreak of pellagra took place. This is declared as a result of antagonism. By injection of nicotinic acid the pellagra symptoms disappeared. H. Kringstad

Recent advances in nutrition. Jennie I. Rowntree. *J. Home Econ* **31**, 635–43(1939).—A review with bibliography. Amy LeVesconte

The vitamin E activity of α-tocoquinone. Oliver H. Emerson, Gladys A. Emerson and Herbert M. Evans. *J. Biol. Chem.* **131**, 409–12(1939).—The vitamin E potency of α-tocoquinone, obtained by oxidation of natural α-tocopherol with $FeCl_3$, is substantially identical with that of tocopherol. A. P. Lothrop

The curative factor (vitamin H) for egg-white injury with particular reference to its presence in different foodstuffs and in yeast. Paul György. *J. Biol. Chem.* **131**, 733–44(1939); cf. *C. A.* **32**, 5447⁸.—Quant. data are presented concerning the distribution of the curative factor (vitamin H) for egg-white injury in different foodstuffs. The main sources of the factor are liver, kidney, yeast and to a lesser extent cow milk. Winter milk is not as potent as summer milk. The curative factor appears to be part of a compd. of higher mol. wt. which is insol. both in H_2O and in fat. It can be freed by autolysis of yeast in the presence of C_7H_8 but not in that of $CHCl_3$, indicating that yeast seems to possess the enzyme necessary for its liberation. **Attempts to isolate the factor (vitamin H) curative of egg-white injury.** P. György, Richard Kuhn and Edgar Lederer. *Ibid.* 745–59.—Vitamin H can be liberated from the dry liver powder remaining after the removal of the liver ext. in the com prepn. of campolon by digestion with papain and autoclaving at high pressure in combination or each by itself, with or without the addn. of acid. It is not set free during autolysis of liver. Further concn. and purification can be effected by pptn. with alc. or Me_2CO, adsorption on charcoal and subsequent pptn. with phosphotungstic acid after elution and the use of a no. of other precipitants. In the most highly purified concentrates 1 rat day dose (daily dose bringing about complete cure in 4 weeks) was contained in 30–40 γ of org. dry residue. The vitamin is inactivated by benzoylation and treatment with

HCHO, HNO_2 and ketene. Its activity was impaired in several concentrates by oxidation with H_2O_2, although not consistently. It was freely dialyzable in papain digests of liver powder or in yeast autolyzates, especially after hydrolysis with H_2SO_4. **Physicochemical properties of the factor (vitamin H) curative of egg-white injury.** T. W. Birch and P. György. *Ibid.* 761–6.—Electrodialysis indicates that vitamin H has an isoelec. point between pH 2 and 4, the actual value appearing to be between 3 and 3.5. The Na salt is sol. and the Ca and Ba are insol. in abs. EtOH. It is not pptd. by alkaloids. Aq. solns. of the highest purity concentrates are unstable and often lose their activity in 4–6 weeks from undetd. causes. S and P are not present and even the most active concentrates are amorphous and gum-like with a brownish color. A. P. Lothrop

The nutritive value of powdered whole milk. R. C. Hutchinson. *Med. J. Australia* **1939, II,** 392–400.—A study of Australian whole milk powder has shown that while it could not replace fresh cow milk it compared favorably chemically and biologically with fresh whole milk. G. H. W. Lucas

Relation between the vitamin C picture in the blood and fever metabolism. F. X. Hausberger and N. Nevensch, wander-Lemmer. *Klin. Wochschr.* **18,** 1119–23(1939).—Although injected ascorbic acid rapidly disappears from the blood of normal persons it disappears even more quickly in patients with a high fever. The concn. in the blood returns to the initial level within an hr. owing to rapid absorption by the tissues which have been depleted of ascorbic acid by the fever. H. L. Mason

Alimentary ketone body formation and liver glycogen. Silvio Markees. *Klin. Wochschr.* **18,** 1123–6(1939).—The level of ketone bodies in the blood of rabbits after feeding Na butyrate was not dependent on the amt. of glycogen in the liver but rather on the amt. of peripheral glycogen. H. L. Mason

Applicability of the thiochrome method for study of the vitamin B_1 economy. Joachim Baucke. *Klin. Wochschr* **18,** 1128–31(1939).—Examn. of Ritsert's procedures (*C. A.* **32,** 6280[1]; **33,** 212[3]) leads B. to conclude that R.'s values are too high by about 7 γ % and that when this correction is made the normal excretion of vitamin B_1 is 25–75 γ, av. 45 γ, in 24 hrs. There are 2 types of response to loading: in one the daily excretion rises quickly, then falls and finally rises again to a plateau; in the other the excretion rises slowly to a high level. The excretion after administration of 1 mg. affords an indication of the degree of satn. of the tissues with the vitamin. H. L. Mason

Loading studies with vitamin B_1. Imre Magyar. *Klin. Wochschr.* **18,** 1157–60(1939).—Normal individuals excrete in 24 hrs. more than 18% of a single large dose (10 mg.) of vitamin B_1 given parenterally. A lesser excretion is indicative of hypovitaminosis. When the vitamin administration is repeated daily the excretion of the hypovitaminotic person increases while that of the normal person decreases. Impairment of kidney function does not reduce the total amt. excreted but delays the excretion somewhat. H. L. Mason

Ascorbic acid and liver glycogen. A. Morelli and L. D'Ambrosio. *Arch. sci. biol.* (Italy) **24,** 351–6(1938).—Ascorbic acid injected subcutaneously in guinea pigs produces an increase in liver glycogen which is more evident when 100 mg. is given. P. F. Metildi

The action of vitamin C on glucemic curves by glucose, adrenaline, insulin and thyroxine. F. Addarii and F. Volpe. *Arch. sci. biol.* (Italy) **25,** 372–92(1939).—Normal and scorbutic guinea pigs weighing 250–300 g. were given 30 mg. ascorbic acid after injection of glucose, adrenaline, insulin and thyroxine. The hyperglucemia after glucose is lower; the action of adrenaline and insulin is increased and that of thyroxine decreased. The authors suggest that ascorbic acid has an amphotonic neurovegetative action, but that the glycopexic power is particularly obvious when large quantities of glucose are given or in glycogen deficiency of the organism (scurvy, diabetes). P. F. Metildi

The glucoregulating action of ascorbic acid in avitaminosis. F. Addarii and F. Volpe. *Arch. sci. biol.* (Italy) **25,** 393–403(1939).—In scorbutic guinea pigs there is a diminished basal glucemia and an insulin-like effect when vitamin C is injected. The basal hypoglucemia is explained by insufficient sorption and metabolism of glucose; the insulin-like effects by rapid improvement of the glycopexic power of the tissues which are almost deprived of glycogen. P. F. Metildi

Calcium deficiencies. Jacques Decourt. *Ann. méd.* **45,** 361–79(1939).—Ca deficiencies are caused by dietary insufficiency or defective absorption in digestion. Physiopathology, symptoms, hypoparathyroidism and hyperparathyroidism produced by reaction are discussed. Treatment consists primarily in the regulation of diet and digestion. Medical treatment by mouth is of little value, since little is retained. Parenteral treatment with $CaCl_2$ and gluconate is more efficacious, but elimination is too rapid unless vitamin D is given simultaneously. A. E. Meyer

The photodynamic hemolysis by chlorophyll of the erythrocytes of herbivorous, carnivorous and omnivorous animals alimented with and without chlorophyll. Orazio Reggiannini. *Biochim. terap. sper.* **26,** 365–79(1939).—The photodynamic hemolysis by chlorophyll cannot be compared with that caused by other photodynamic substances. The degree of hemolysis changes in the different species and within each species from one animal to another. It also changes with variation in alimentation: prolonged feeding with green vegetables augments the globular resistance to a max. The erythrocytes of carnivorous animals are more resistant than those of herbivores. A. E. Meyer

The action of vitamin excess and of deficiency diets on the thyroid. G. Carrière, J. Morel and P. J. Gineste. *Bull. acad. méd.* **121,** 324–8(1939).—Daily doses of 10,000 to 25,000 units of vitamin A and 50 to 100 mg. ascorbic acid subcutaneously inhibited the activity of the thyroid in the rabbit and finally led to a gland of the same structure as is found in colloid goiter. Similar effects are seen in rats. Vitamin B_1 in doses of 10 to 20 mg. per day caused a moderate stimulation in guinea pigs. The vesicular epithelium became cylindric and hypertrophic. Several mg. of vitamin D produced intense hyperplasia with numerous mitoses in the rabbit. Prolongation of this treatment led finally to degeneration of the gland. Deficiency of A in the rat led to histological signs of hypersecretion with gradual decrease in colloid and ending in desquamation of the epithelial elements and atrophy. C deficiency in guinea pigs is assocd. with hyperactivity of the thyroid. Conclusions: A and C are recommended in hyperthyroidism. D and heliotherapy are contraindicated in hyperthyroidism but seem to be useful in hypothyroidism. Clinical observations seem to substantiate these results obtained in expts. A. E. M.

Resistance of ascorbic acid (vitamin C) to the action of heat. Jean Pien and Herbert Meinrath. *Compt. rend.* **209,** 462–4(1939).—Vitamin is destroyed by heating in the presence of O_2. But it is easily oxidized even by cold air. If heated in the absence of air, however, it is stable. Ascorbic acid in solns. of pH 0.64 to 8.0 was heated at 120° for 5–30 min. in O_2, air, N or CO_2. In O_2, 2% of the initial ascorbic acid was recovered at pH 8.0 to 13% at pH 3.2; in air, 51% was recovered at pH 8.0 to 60% at pH 3.2; while in N or CO_2, 88% was recovered at pH 8.0 to 96% at pH 3.2. In all atms., there was a decrease in the amt. of ascorbic acid recovered with an increase in time of heating and in alky. Dorothy A. Meyer

Vitamin C in blood and urine by intravenous saturation. Leo Skurnik and Heinz Groth. *Acta Med. Scand.* **101,** 321–32(1939).—Ascorbic acid was injected intravenously into rabbits in amts. of 150 to 500 mg. and the ascorbic acid in blood and urine was detd. at short intervals afterward. These studies suggested that within 5 min. a considerable portion of the vitamin C was fixed by the tissues, and this was borne out by an actual examn. of tissues of animals killed 5 min. after the injection as compared with the same tissues from control animals. A

large increase was found in the liver, small intestine and muscles, while the brain did not show any marked increase. With the muscles a max. concn. was obtained with an injection of 250 mg. ascorbic acid. Where the tissues of the animal were already satd. with ascorbic acid, injection brought about a great rise in the blood but had no effect on the tissues. S. Morgulis

Intravenous saturation with vitamin A. Heinz Groth and Leo Skurnik. *Acta Med. Scand.* **101**, 333–7(1939). - Vitamin A finely emulsified with Na oleate and physiol. saline was used for intravenous administration. To det. vitamin A in blood saponify 2 cc. serum with 2 cc. 40% KOH for 1 hr. on the water bath in a N_2 atm.; cool, add 4 cc. alc. and shake in a separatory funnel; again shake with 4 cc. petr. ether. Remove the ether layer, wash several times with H_2O and dry with Na_2SO_4. After evapg. in a N_2 atm. the residue is dissolved in $CHCl_3$ and used to det. vitamin A by the Carr-Price (cf. *C. A.* **20**, 3020) procedure. Initially the rabbit blood contained 270–570 international units per 100 cc. serum and on injecting of even immense quantities of vitamin A the blood serum content did not show any marked increase, even right after the injection. In expts. where the rabbits were given up to 360,000 units intramuscularly, then on the following day 36,000 units intravenously, the serum vitamin A content did not go above 2040 units per 100 cc. It is concluded that the tissues take up vitamin A with exceptional rapidity, as none appears in the urine. Similar results were obtained on a man. S. Morgulis

The experimental production of nephritis in rats by means of parathyroid hormone and of vitamin D. Bruce Chown, Margaret Lee, John Teal and Robert Currie. *J. Path. Bact.* **49**, 273–90(1939).—Nontoxic vitamin D in very large doses may occasionally lead to chronic nephritis in the rat. Parathyroid hormone nephritis is due to the deposition of Ca within and around the tubules, with obstruction leading to atrophy of some nephrons and dilatation of others. 24 references. John T. Myers

Vitamin F. F. Grandel. *Fette u. Seifen* **46**, 150–2 (1939).—The vitamin nature of certain unsatd. higher acids and the utility of the Shepherd-Linn biol. test for vitamin F were confirmed. Comparative tests show that the esters and soaps of a fatty acid prepn. having pronounced vitamin F activity must be hydrolyzed within the body to the free acid before exerting vitamin F activity. Cf. S. and L., *C. A* **30**, 5267[5]. J. W. Perry

Prophylactic and curative effect of vitamin K in hemorrhagic disease of the newborn (hypothrombinemia hemorrhagic neonatorium). K. K. Nygaard. *Acta Obstet. Gynecol. Scand.* **19**, 361–70(1939).—Preliminary studies showed the prothrombin time to be normal at the time of birth. From the second half of the first day to the 6th day of life, a physiol. transitory hypothrombinemia occurred. In the majority of the newborn with hemorrhagic disease, the onset of hemorrhage occurred during this period. The administration of vitamin K immediately after delivery successfully prevented the development of transitory hypothrombinemia. Vitamin K administered to 3 cases of hypothrombinemia hemorrhagic neonatorum exhibited a therapeutic effect equaling that of blood transfusion. Maurice M. Rath

Optimal and minimal vitamin C requirements of the human subject. H. Rietschel. *Munch. med. Wochschr.* **86**, 811–15(1939); cf. *C. A.* **33**, 2565[6]. M. M. R.

Use of vitamin C against infection. Alfred Enders. *Munch. med. Wochschr.* **86**, 822(1939). M. M. R.

Creatinuria in vitamin E deficiency and its cure by *dl*-α-tocopherol acetate (synthetic vitamin E). F. Verzar. *Schweiz. med. Wochschr.* **69**, 738–41(1939); cf. *C. A.* **33**, 8714[8]. - Rats fed a diet lacking vitamin E for a no. of months developed muscular dystrophy and creatinuria. Daily administration of 50 mg. of synthetic vitamin E produced some effect in these animals, but it took 200 mg. daily to restore normal creatine values. V. believes that creatinuria in this condition is a result of disturbed muscular metabolism on the one hand and reduced secretions of the anterior lobe of the pituitary and sex glands on the other. Vitamin E counteracts this disturbance and fixes creatine in the tissues. Thirty-eight references. Maurice M. Rath

Effects of ketogenic diet. M. Julesz and E. Winkler. *Schweiz. med. Wochschr.* **69**, 807–10(1939). -A ketogenic diet diminished the alkali reserve of both asthmatic and nonasthmatic groups from 1 to 20%. No quant. difference in NH_3 secretion between controls (650 mg.) and the asthmatic patients (630 mg.) was observed. Phosphoric acid also did not have any appreciable effect. A ketogenic diet in nonasthmatic controls increased the NH_3 elimination by 45–50% as compared with the standard diet. The increased NH_3 excretion continued for 1 to 3 weeks with acetonuria and then decreased at which time not even increased ketosis could enhance NH_3 excretion. J. and W. differentiate between 4 kinds of effects on ammonia excretion in asthmatic patients who are on a ketogenic diet. Maurice M. Rath

The significance of vitamin C in the treatment of Addison's disease. Jaroslav Pojer. *Schweiz. med. Wochschr.* **69**, 872–4(1939).—Vitamin C (1 g. given daily) diminished the K blood level in 2 cases of beginning Addison's disease. Na and chloride levels did not show any significant variation. General improvement and diminishment of pigmentation were observed. Maurice M. Rath

Effect of vitamin C upon glycogen depot. Susumu Simizu. *Tohoku J. Exptl. Med.* **36**, 211–30(1939). - Lecithin given intravenously depleted the glycogen depot in the liver of the rabbit but increased the vitamin C content. $CHCl_3$ depleted the glycogen and also diminished the vitamin C. Rabbits fed a vitamin C-rich diet showed increased vitamin C in the liver which paralleled an increase in glycogen. The glycogen depot of these animals resisted the action of lecithin and $CHCl_3$. M. M. R.

The effect of fever therapy upon carbohydrate metabolism. Melvin B. Kirstein and Leon Bromberg. *J. Lab. Clin. Med.* **25**, 7–10(1939). - The results show an increase in the sugar and nonprotein N concns. and a decrease in the inorg. P concn. in the blood of patients during fever therapy. The hypoglucemia is not due to blood concn. (Simpson, *J. Am. Med. Assoc.* **100**, 67 (1933); Hench and Slocumb, *Proc. Staff Meet. Mayo Clin.* **10**, 202(1935)) but to disturbances in carbohydrate metabolism. The rate of glucose utilization is increased. With this concept such patients should receive liberal carbohydrate diets before and between treatments. H. W. Robinson

The value of the bones of canned salmon in the prevention and cure of rickets. Basil E. Bailey. *Fisheries Research Board Can., Progress Repts. Pacific Stas.* No. 41, 17–19(1939). Expts. were conducted to det. whether the bone in canned salmon, which is made edible by the canning process, can be utilized by the body, as evidenced by the prevention and cure of rickets in young albino rats. The backbone and large rib bones were taken from canned pink salmon, adhering flesh was carefully removed, and the bones were extd. with ether to remove vitamin D. The dried and pulverized product contained 4.9% Ca and 6.5% P. Rats receiving a rachitogenic diet developed severe rickets in 23 days, whereas other animals receiving the same diet to which 2% pulverized salmon bones was added developed no rickets in 23 days, and were only slightly rachitic after 30 days. Curative tests showed that addn. of 1% salmon bones to the rachitogenic diet was without effect, 2% caused slight recalcification and 1% resulted in very definite, but still incomplete, recalcification. W. Gordon Rose

Studies on dietary requirements for lactation. VIII. Effect of withdrawal of vitamin L_1 during lactation. Waro Nakahara, Humito Inukai and Saburo Ugami. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 312–17 (1939); cf. *C. A.* **32**, 5457[5].—Withdrawal of vitamin L_1 supplement from the diet of rats that have been receiving this vitamin in amts. barely sufficient to maintain lactation results in serious interference with the lactation process, and consequent death of the young during the third week. If the previous supply of the vitamin in the diet was quite adequate, subsequent removal of the vitamin from the diet is without effect. None of the young

suckled up to the end of the second week died during the third week if the minimal supply of the vitamin was continued during this period. **IX. Vitamin L deficiency in mice.** Waro Nakahara, Humito Inukai, Saburo Ugami and Kenzo Takahasi. *Ibid.* 318–26.—Mice are less susceptible than rats to vitamin L deficiency and must be maintained on a deficient diet 90 days prior to parturition to produce a low level of lactation. **X. Notes on the methods for vitamin L tests.** Waro Nakahara, Humito Inukai and Saburo Ugami. *Ibid.* 327–34.—Satisfactory vitamin L tests can only be obtained if appropriate conditions are observed. Only virgin female rats must be used. The proper source of vitamin B (acid earth adsorbate of bakers' yeast) must be used, since bakers' yeast contains vitamin L_2 and brewers' yeast contains both vitamins L_1 and L_2. The failure of Foltoy, *et al.* (*C. A.* **33**, 3430[8]) to duplicate Nakahara's results is attributed to the inclusion of brewers' yeast in the diet used by the former. The constituents of 3 different types of vitamin L-deficient diets are listed.
W. Gordon Rose

Multiple nature of the rat "filtrate factor" - a component of vitamin B_2. Adi Mohammad, Oliver H. Emerson, Gladys A. Emerson and Herbert M. Evans. *Science* **90**, 377(1939).—The MeOH-sol. fraction from cane molasses was adsorbed on fuller's earth. The filtrate was acidified and extd. for 72 hrs. with Et_2O in a continuous extractor (Prepn. I). The residue was subjected to a 2nd 72-hr. extn. (Prepn. II). These extns., as well as the residue (Prepn. III), were fed to female rats maintained on a vitamin B complex-deficient diet supplemented with thiamin, riboflavin and a source of B_6 in the form of a wheat-germ eluate. Each prepn. was fed for 56 days at the equiv. of 3 g. daily of the original molasses. The gain in wt. (above that of the controls) was: Prepn. I, 60 g., Prepn. II, no gain, Prepn. III, 58 g. Black, gray and hooded rats which received Prepn. I showed no change in pelage coloring. Those which received Prepn. III showed a marked graying of black hair and a lightening of gray hair, although the nutritive state and growth were essentially the same in groups I and III. An iso-AmOH ext. of a rice bran prepn. was prepd. Its activity was not destroyed by heating at 100° for 1 hr. in *N* NaOH. The factor extractable with iso-AmOH is not identical with the "chick dermatitis factor." F. Saunders

Investigations on the gastric emptying time of heated and acidified breast milk in premature infants. H. K. Birmele. *Monatsschr. Kinderheilk.* **78**, 201–10(1939). — When fed to premature infants raw, sterilized, briefly heated, and acidified breast milks did not show any differences in gastric emptying time, the averages being 2.7, 2.7, 2.6 and 2.7 hrs., resp. H. P. G. Seckel

Bringing up of premature infants on raw breast milk to which gelatin or carbohydrates were added. H. Kohl. *Monatsschr. Kinderheilk.* **78**, 211–20(1939).—In 31 premature infants it was shown that by adding 2% gelatin, i. e., certain protein mols. such as glycine, lysine, arginine, to genuine breast milk, the weight growth of premature infants could be improved almost without exception, often to a considerable degree. No such effect was seen in a control group of premature infants fed on breast milk to which equicaloric amts., i. e., 2%, of Dextromaltose or "Dextropur" were added. H. P. G. S.

Incurable rickets. S. Liebe. *Monatsschr. Kinderheilk.* **78**, 221–6(1939).—A boy 2½ years old who had a birth wt. of 3.5 kg. and whose father twice had had spontaneous fractures (blood P 2.0 mg. %, Ca 7.9 mg. %) was shown to have all clinical, röntgenological, and chem. signs of acute rickets. He remained uninfluenced by 15 weeks' treatment by mouth and intramuscularly with various types of vitamin D, D_2 and D_3. All this time the blood P varied between 1.9 and 3.0 mg. %, the blood Ca between 7.3 and 8.5 mg. % (with the exception of one 9.5 figure). After 5 months without treatment, 12 injections of 0.3 cc. each of parathormone were given in 6 weeks; at the end of this period the blood P was 3.1 and the Ca 7.2 mg. %. No change in the x-ray findings took place during the treatment. The urinary tract of the boy was normal. The fat absorption from the bowels was 96.7% of the intake. A familial constitutional anomaly of the bones or the absence of a link in the anti-rachitic mechanism was suggested as an explanation for this case. H. P. G. Seckel

Effect of water deficiency on carbohydrate metabolism. Ö. Kerpel-Fronius and A. Fekete. *Monatsschr. Kinderheilk.* **78**, 349–52(1939); cf. *C. A.* **33**, 8739[2].—Nine young albino rats weighing 99–140 g. were divided into 3 groups of 3 animals each. All of them were kept fasting for 48 hrs., group I with free access to water, group II without water, and group III without water plus "repeated" gavaging of a 15% soln. of urea. At the end of this period, 2 cc. of a 40% glucose soln. was given by gavage to all 3 groups of rats. After 3 hrs., the animals were killed and analyzed for glucose retention in the intestine (according to Cori) and total liver glycogen (according to Pflueger; Hagedorn-Jenssen). Av. figures found in the 3 groups were:

Group No.	Fasting condition	Weight loss, %	Intestinal glucose retention, %	Total liver glycogen	Glycogen built up from glucose, %
I	Access to water	13	7 5	102 mg	16.7
II	Thirst	17	16.6	82.5 mg.	15 3
III	Thirst plus urea	21	42.4	122 mg.	31.0

Intestinal absorption of glucose is, therefore, inhibited by, and corresponding to the degree of exsiccosis. Nevertheless, liver glycogen is built up from absorbed glucose in normal or even increased abs. amts. during severe exsiccosis, probably because of a decrease in peripheral utilization or storage of glucose. H. P. G. Seckel

Effect on winter rickets and spasmophilia of 3 mg. vitamin D_2 and D_3 "shock" therapy. H. Brieger. *Monatsschr. Kinderheilk.* **79**, 216–29(1939).—In 29 infantile cases of acute rickets without or with either latent or manifest spasmophilia 3 mg. vitamin D_2 or D_3 was given by mouth as a single dose. The results can be summarized in the following table:

Stage of disease	Vitamin D	Days required for cure: Bones	Blood P	Blood Ca	Tetan
Acute rickets	D_2	18	12–16	12–16	..
	D_3	18	8–12	8–12	..
Acute rickets with latent tetany	D_2	11–14	longer	longer	.
	D_3	11–14	shorter	shorter	.
Acute rickets with manifest tetany	D_2	10–12	..	8–12	4–5
	D_3	7	...	8–12	2–3

Complicating diseases prolong the cure. Two cases of rickets in premature infants could not be cured by this treatment. H. P. G. Seckel

Efficiency of vitamin D in different solvents. S. Liebe. *Monatsschr. Kinderheilk.* **78**, 376–83(1939).—In rat expts. Gerstenberger's view concerning better efficiency of peroral than of parenteral application of vitamin D was confirmed, the liver apparently being indispensable for its full effect. Given by both routes, the effect of vitamin D seemed to be independent of the solvents used (sesame oil or propylene glycol) in babies as well as rats. Routine detns. of Ca and P were made in the blood. H. P. G. Seckel

The influence of vitamin C on the growth of Brown-Pearce rabbit carcinoma of the testicle. Gentetsu Ryo. *J. Chosen Med. Assoc.* **29**, 1184–92(English abstr. 77–8)(1939).—A daily abdominal subcutaneous injection of 50 mg. vitamin C per kg. body wt. for 5 days prohibits the growth of a tumor inoculated in the testicle. When the right testicle is inoculated with a suspension of tumor cells alone, and the left is inoculated with it together with 100 mg. vitamin C, both testicles show the absence of tumor cells, although strong inflammatory reactions occur in both. S. Tashiro

The influence of vitamins A and D on abnormal bone growth caused by continuous feeding of inorganic iron. Sakae Taniguti. *J. Oriental Med.* **30**, 945–6(English abstr. 265)(1939).—Iron rickets produced by continuous feeding of $FeCO_3$ or reduced Fe can be prevented if A and D are added to the diet. S. Tashiro

Dietary therapy against calcium oxalate stones in the urinary tract. Greta Hammarsten. *Kgl. Fysiograf. Sällskap. Lund, Forh.* **7**, 37–9(1937)(Pub. 1938)(in German); cf. *C. A.* **31**, 7999[2]; **33**, 698[6].—A diet rich in Ca and Mg and in vitamins A, B, C, D and E was fed to 6 rats with kidney and bladder stones (demonstrated röntgenologically). At autopsy 2 months later, partial or complete cures were found. Conclusion: Ca oxalate stones are principally caused by a deficiency in Ca, Mg and vitamins A and D. W. C. Tobie

Boron in animal nutrition. E. Hove, C. A. Elvehjem and E. B. Hart. *Am. J. Physiol.* **127**, 689–701(1939).—A colorimetric method for the detn. of B in biol. materials is described. This method is subject to a 10% error between 0.5 and 5 γ. The milk from 22 cows was analyzed for B. There is no significant difference between breeds, nor for different periods of the lactation cycle. It is possible to increase the B concn. of the milk tenfold in the 1st 24 hrs. after feeding 13 g. of boric acid. Normal egg whites contain 8–10 times more B than egg yolks. This ratio is not altered significantly when the hens are placed on a high B ration, although the abs. amts. increase greatly. B, fed as boric acid, can pass through the placenta and into the milk of rats. Boric acid fed to rats is eliminated with extreme rapidity. The addn. of B to milk does not produce better growth in young rats. The addn. of B to a dry ration which allows only 0.8 γ of B per rat per day does not result in better growth. If B is needed for the growing rat then this amt. of B per day satisfies that requirement. E. D. Walter

The influence of vitamin C on the growth of tissue in vitro. S. Nakano and I. Sawai. *Japan. Z. Mikrobiol. Path.* **33**, 279–89(1939).—A vitamin C soln. of high concn. inhibits the growth of the cardiac tissue of chicken embryo or splenic tissue *in vitro*, and accelerates it at low concn. I. S. Yun

Effects of sucrose in the diet upon the growth of albino rats. Kosaburo Hirokawa. *J. Med. Coll. Keijo* **9**, 135–48 (1939).—The growth of animals fed on a diet contg. 50% sucrose was in all cases inferior to the growth of animals fed on a normal sucrose-free diet. Animals fed on a diet contg. 50% of sucrose, with dry brewery yeast or vitamin B_1 prepn. (powdered Oryzanin) showed nearly normal growth. When liquor was substituted for Oryzanin powder growth was subnormal. Conclusion: Some special dietary factor contained in dried brewers' yeast is needed to maintain the normal metabolic process of animals fed diets contg. a large amt. of sucrose. I. S. Yun

Use of cull apples as feed for dairy cows (Knott) **12**. Chemistry of vitamin E (Evans, *et al.*) **10**. Naphthoquinones of the vitamin K_1 type of structure (Fieser, *et al.*) **10**.

F—PHYSIOLOGY

HOMER W. SMITH

Effect of progesterone on the mouse ovary as influenced by gestation. Hans Selye. *Anat. Record* **75**, 59–73 (1939).—One mg. daily for 5 days causes corpus luteum involution and marked ovarian atrophy. The gonadotropic hormone of the placenta which maintains the corpora lutea of gestation is not inhibited by progesterone. Delivery and onset of lactation are not prevented by massive doses. Philip D. Adams

Effect of sex hormones on the gonads of frog larvae (Rana clamitans); sex inversion in females; stability in males. C. L. Foote and Emil Witschli. *Anat. Record* **75**, 75–83(1939).—In sexually differentiated larvae transformation of ovaries into testes is induced by testosterone propionate. Estrogenic hormones have little effect on the structure of the testes. Philip D. Adams

Action of estrone on sexual organs of immature male cats. W. F. Starkey and J. H. Leatham. *Anat. Record* **75**, 85–9(1939).—Hypertrophy of the glandular epithelium of the prostate resulted in immature male cats treated with estrone. Metaplasia of the urethral and ductal epithelium also occurred in the absence of leucocytic infiltration. Philip D. Adams

Reduction of osmic acid as an indicator of adrenal activity in the rat. Louis B. Flexner and Arthur Grollman. *Anat. Record* **75**, 207–21(1939).—Reduction in adrenal activity was induced by the administration of various amts. of cortical hormone; activity was stimulated by unilateral adrenalectomy, heat, cold, tetrahydro-β-naphthylamine, thyrotropic hormone or inanition. Philip D. Adams

Measurement of the gonadotropic activity of prehypophyseal extracts. Raymond Cahen and Pierre Ardoint. *Compt. rend.* **209**, 490–1(1939).—The gonadotropic activity of prehypophyseal exts. was measured by 3 methods: (1) the percentage of estrus caused in a no. of hypophysectomized rats, (2) the increase in the size of the comb of immature cocks and (3) the increase in wt. of the testicles of immature cocks. The first method is difficult, the second relatively simple but not very accurate while the third is accurate but also onerous. Rachel Brown

The influence of internal secretion on the vitamin C content of the aqueous humor and various organs. III. The influence of the Zondek "prolan" of the anterior pituitary. Experiments on adult female rabbits. N. Itikawa. *Folia Endocrinol. Japon.* **15**, 31–2(1939)(in German).—The exptl. procedure was the same as in *C. A.* **33**, 9391[2]. Prolan was prepd. from human pregnancy urine by the Zondek method of alc. pptn. The amt. of prolan injected daily corresponded to 10 cc. original urine. The vitamin C content of the aq. humor of normal or ovariectomized rabbits was decreased on the 5th day of injection and, to a greater degree, on the 10th day; 1–2 weeks after the last (10th) injection the vitamin C gradually increased and approached its initial level. The percentage ratio (vitamin C content per organ wt.) decreased immediately as well as 2 weeks after the 10th injection, the decrease being greatest in the adrenal, smaller in the spleen and liver and smallest in the ovary. The vitamin C in the aq. humor increased 1 week after ovariectomy and then gradually decreased to the initial level. IV. **The influence of the so-called Zondek "prolan." Experiments on adult male rabbits.** *Ibid.* 33–4.—If the prolan was injected into normal or orchidectomized rabbits daily for 10 days, the vitamin C content of the aq. humor decreased slightly on the 5th day of injection and, to a greater extent, on the 10th day immediately after the injection; it gradually decreased up to a week after the last (10th) injection and only began to increase slowly 2 weeks after the last injection. The percentage of vitamin C in the organs decreased immediately as well as 2 weeks after the 10th prolan injection, the percentage decrease being greatest in the adrenal, smaller in the spleen and liver and smallest in the testes. The vitamin C content of the aq. humor gradually increased 7–12 days after orchidectomy; on the 19th and 26th days after the operation the vitamin C decreased and approached its initial value. V. **The nature of the action of the Zondek "prolan."** *Ibid.* 35.—In order to avoid the direct effect of the operation, prolan was not injected into the rabbits until 4 weeks after a thyroidectomy or until 3 weeks after a splenectomy. The prolan (injected once daily for 10 days) decreased the vitamin C content of the body of thyroidectomized but not of splenectomized rabbits. The action of prolan on the vitamin C metabolism is splenotropic in nature; it does not require the presence of the thyroid or sex glands. Ruth Berggren

The influence of various endocrine disturbances on the action of the gonadotropic hormone of the anterior pituitary. III. The relation between the gonadotropic hormone and functional anomalies of the thymus. Y. Yamao. *Folia Endocrinol. Japon.* **15**, 36(1939)(in German); cf. *C. A.* **33**, 9390[8,9].—In young white rats weighing about 30 g. the accelerating action of the gonadotropic hormone on the development of the ovary and uterus was slightly lowered after thymectomy or by preliminary feeding with thymus powder. The thymus exerts no direct hormonal regulatory action on the ovary. IV. **The relation between the gonadotropic hormone and**

functional anomalies of the spleen. *Ibid.* 37.—The gonadotropic hormone from pregnancy urine was injected once daily for 5 days into white rats weighing 30–45 g. Splenectomy had no effect on the accelerating action of the gonadotropic hormone on the development of the ovary and uterus for 10 days after the operation. If the gonadotropic hormone was not injected until 1 month after splenectomy, its effect on the ovary and uterus was distinctly inhibited. Ruth Berggren

The influence of the so-called anterior pituitary hormone (prolan) on the tissue oxidases in white rats. I. Experiments on normal female and male white rats. Yosiro Yamao. *Folia Endocrinol. Japon.* **15**, 40–1(1939)(in German).—In the female rats the oxidase content of the heart, liver and kidney, detd. by the Vernon method (*C. A.* **6**, 2251), was increased during estrus. Upon prolonged subcutaneous injection of the gonadotropic hormone of the anterior pituitary from human pregnancy urine the oxidase content of these organs decreased, the decrease being greater in the female than in the male rats. **II. Experiments on castrated, splenectomized and splenectomized-ovariectomized rats.** *Ibid.* 41–2.—Gonadotropic hormone of the anterior pituitary, corresponding to about 40 cc. original urine, was injected subcutaneously beginning usually 2 weeks after castration and continuing for 13 successive days. Some of the rats were simultaneously splenectomized and ovariectomized. The rest of the exptl. procedure was the same as that given above. The gonadotropic hormone caused a decrease in the tissue oxidases of the heart, liver and kidney in ovariectomized rats and of the liver and kidney in orchidectomized rats, but produced an increase of the oxidase content of the heart in the latter. The gonadotropic hormone did not cause a lowering of the oxidase content of these organs in splenectomized male or female rats. The oxidase-lowering action of the gonadotropic hormone is splenotropic in nature. Ruth Berggren

The effect of diethylstilboestrol in the male organism. J. H. Gaarenstroom and S. E. deJongh. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 178–81 (1939); cf. *C. A.* **33**, 3854⁷.—Tests on immature male mice and rats and on full-grown male rats showed that 5 γ of diethylstilboestrol had the same antimasculine and paradoxical effects on the sex organs as did 5 γ of estrone. Rats injected with diethylstilboestrol grew more slowly than did those injected with estrone. E. Curzon

The optimum range of oxygen tension. R. Brinkman and A. H. J. Wildschut. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 187–90(1939).—Quant. measurements of O_2 consumption in the skin were made by measuring the rate of reduction of oxyhemoglobin in the finger with stopped circulation and at const. temp. During the expt. gas mixts. low in O_2, normal air and pure O_2 were breathed. Results indicated inhibition of oxidative metabolism in the skin during conditions of low- or high-O tension. E. Curzon

Effect of the thyreotropic hormone on the basal metabolism of the rabbit. Jacques Mahaux. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 209–12 (1939); cf. *C. A.* **33**, 7057.—Rabbits 2–3 yrs. old injected with 100–200 Heyl and Laquer units of thyreotropic hormone show an elevated metabolism for 12–16 days. If, shortly after the metabolism has returned to normal, thyreotropic hormone is again injected, no such elevation is seen. Conclusion: The degree of modification of thyroid gland activity which results from the administration of a given dose of thyreotropic hormone appears to depend on the quantity of an inhibiting principle present in the injected animal. E. Curzon

Circulatory modifications during experimental hypothyroidism in the dog. Jean Lequime. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 233–5(1939).—In exptl. hypothyroidism in 2 dogs a considerable decrease in the cardiac debit is observed, owing to a decrease in tissue metabolism and to the increase in the arteriovenous difference. E. Curzon

Influence of the sino-carotid reflex on the blood flow of the kidney and on diuresis. H. Handovsky and Adli Samaan. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 243–5(1939). E. Curzon

The possible therapeutic influence of work metabolism in low pressure. A. Rühl, W. Kühn and G. Müller. *Luftfahrtmed.* **3**, 285–301(1939).—Criteria of success in metabolic adjustments to O lack were increased max. O intake, lower work R. Q., decreased work acidosis, and fewer respiratory disturbances. Repeated work expts. had therapeutic value as judged by these tests. Cardiazole and coramine were useful only in collapse. While the addn. of about 5% CO_2 increased the max. O intake in low pressure, the extra strain thus placed on the respiratory center is objectionable. D. B. Dill

Variations throughout 24 hours in the elimination of the principal substances of urine. Simone Belluc, J. Chaussin, H. Laugier and Thérèse Ranson. *Travail humain* **7**, 62–73(1939); cf. *C. A.* **33**, 7358⁴.—In one subject on a const. diet, urinary output of water, Cl and uric acid varied with one another in 4-hr. periods throughout the day, while NH_3 output fell as the vol. increased. Urea was excreted at a rate reflecting its const. production. D. B. Dill

Influence of long-continued exercise on the functional activity of the adrenal cortex of man. Gr. Benetato. *Travail humain* **7**, 153–62(1939).—Injection of histamine produced smaller changes in blood pressure in trained than in untrained subjects. In the latter there was some correlation of the response with body build. D. B. Dill

Effects of drinking large volumes of water on urinary excretion. Simone Belluc, J. Chaussin, H. Laugier and Thérèse Ranson. *Travail humain* **7**, 163–75(1939).—Drinking 2.4 l. of distd. water or 2 l. of Évian increased urea excretion 15 and 20%, resp., during the period in which the excess water was eliminated. Other constituents were unaffected. D. B. Dill

Blood oxalate. A. Leulier and J. Dorche. *Compt. rend. soc. biol.* **132**, 5–7(1939).—Large samples of serum were digested with pepsin and HCl, then filtered and oxalic acid was detd. as previously described (*C. A.* **33**, 192¹). Horse serum contained 2.3–2.7 mg. $H_2C_2O_4$ per l., beef serum 2.18–2.76 and sheep serum 3.02–3.86. L. E. G.

Osmotic resistance of reticulocytes. Z. Beranek. *Compt. rend. soc. biol.* **132**, 22–4(1939).—It was not found possible to sep. reticulocytes from erythrocytes by fractional hemolysis of rabbit blood. L. E. Gilson

Carbohydrate metabolism of the crystalline lens. Roger Weekers. *Compt. rend. soc. biol.* **132**, 36–8(1939).—In Ringer or Tyrode soln., without glucose, the isolated lens of the rabbit begins to turn opaque after 2–3 days at 36.5°. The addn. of 0.1% of glucose to the soln. delays opacification about 3 days; levulose and galactose have no such effect. L. E. Gilson

Lactogen content of female guinea-pig pituitary. R. P. Reece. *Proc. Soc. Exptl. Biol. Med.* **42**, 54–6(1939).—The lactogen content increased very slightly in pregnancy and showed a small further increase during the lactation period. The max. observed was 16.5 bird units per whole gland. L. E. Gilson

Plasma pH, blood carbon dioxide and "tissue gas" tensions during hibernation. R. T. Stormont, Mark A. Foster and Carl Pfeiffer. *Proc. Soc. Exptl. Biol. Med.* **42**, 56–9(1939).—During hibernation of ground squirrels (*Citellus tridecemlineatus*, Mitchill) arterial blood CO_2 increased to an av. of 85.7 vol. % (normal is 45.5) and plasma pH decreased to 7.1 from a normal av. of 7.43. The tensions of CO_2 and O_2 in the peritoneal gas pocket decreased significantly. L. E. Gilson

Coagulation time of blood in normal and adrenal-medullated rats. Dwight J. Ingle and Warren C. Corwin. *Proc. Soc. Exptl. Biol. Med.* **42**, 82–4(1939).—After removal of the adrenal medulla the rats responded like normal rats in respect to the coagulability of the blood after emotional excitation and after Et_2O anesthesia. L. E. Gilson

Some effects of testosterone on sexual differentiation of female albino mice. C. D. Turner, Rita Haffen and Helen Struett. *Proc. Soc. Exptl. Biol. Med.* **42**, 107–10 (1939).—Prenatal and postnatal treatment produced

intersexual forms. Changes in the genital tract are described. L. E. Gilson

Influence of age of animal and nature of injected hormone preparation on antihormone production. Albert S. Gordon, Irving Levenstein and Harry A. Charipper. *Proc. Soc. Exptl. Biol. Med.* **42**, 121–6(1939).—Mature rats (only females were used) produce more antihormone in response to injections of anterior pituitary-like gonadotropic prepns. than rats which are immature when treatment is begun. Of 2 gonadotropic prepns. tested, the one contg. much protein (pregnant mare serum) evoked less antihormone production but more precipitins than the one contg. less antigenic material (ext. of human pregnancy urine). L. E. Gilson

Effect of age on the cellular phases of skeletal muscle. H. M. Hines and G. C. Knowlton. *Proc. Soc. Exptl. Biol. Med.* **42**, 133–5(1939).—Detns. are given of the Cl, fat and water contents of gastrocnemius muscles and serum from 7 groups of rats ranging from 15 to 365 days old. Values characteristic of adult tissue are found at 90 days of age. Thereafter the compn. is practically const. The muscle contains 40% connective tissue at 15 days and 15% at 90 days. The water content of muscle cells decreases during the growth period. L. E. Gilson

Effects of activity on tissues of the rat. J. T. McClintock, H. M. Hines and Dorothy P. Jordan. *Proc. Soc. Exptl. Biol. Med.* **42**, 139–42(1939). The muscles of adult male and female rats kept in revolving activity cages contained about 20% more tissue hemoglobin than those of rats not allowed to exercise. There were no significant differences in the N and creatine of the muscles of the 2 groups. L. E. Gilson

[Unsuccessful] attempts to demonstrate vasopressor properties in the serum of hypertensive dogs. M. F. Mason and J. D. Rozzell. *Proc. Soc. Exptl. Biol. Med.* **42**, 142–4(1939). L. E. Gilson

Is pantothenic acid essential for the growth of rats? J. J. Oleson, D. W. Woolley and C. A. Elvehjem. *Proc. Soc. Exptl. Biol. Med.* **42**, 151–3(1939). Rats require the intact pantothenic mol. Alkali-treated concentrates contg. both the β-alanine and dihydroxy acid fractions are not sufficient. L. E. Gilson

Absorption of water by liver slices from physiological saline solutions. Warren M. Sperry and Florence C. Brand. *Proc. Soc. Exptl. Biol. Med.* **42**, 147–50(1939). Rat liver slices absorb water rapidly from 0.9% NaCl, Tyrode and Krebs solns. Within 10 min. an amt. of water equal to the dry matter wt. of the tissue is usually absorbed. A moist chamber for storing and slicing tissues is described. L. E. Gilson

Metabolism of human spermatozoa. John MacLeod. *Proc. Soc. Exptl. Biol. Med.* **42**, 153–5(1939). In Ringer phosphate soln. respiration is too slow to be measurable. In Ringer glucose soln. metabolism is almost exclusively glucolytic and not respiratory. Aerobic lactic acid production is 80% of the anaerobic and falls off with time, whereas anaerobic glucolysis is linear for many hrs. Max. motility is maintained for over 3 hrs. under anaerobic conditions but decreases markedly in the same period in presence of air or pure O_2. This suggests that O has an inhibiting effect on the normal function of human spermatozoa. L. E. Gilson

Relaxation of the pelvic ligaments of the guinea pig induced by progesterone. Hans O. Haterius and N. W. Fugo. *Proc. Soc. Exptl. Biol. Med.* **42**, 155–7(1939).—Cryst. progesterone is quite effective in inducing relaxation of the pelvic ligaments when administered to the oöphorectomized guinea pig previously primed with repeated large doses of estradiol benzoate. Estradiol benzoate alone was ineffective. L. E. Gilson

Lipide distribution in rat liver after partial hepatectomy. Stephan Ludewig, G. R. Minor and J. C. Mortenstine. *Proc. Soc. Exptl. Biol. Med.* **42**, 158–61(1939).—Liver injury produced by partial hepatectomy causes a marked disturbance in lipide metabolism in the liver. Neutral fat, phospholipides, cholesterol and cholesteryl esters increase; total fat-free solids decrease. The I no. of the phospholipides increases. The return to normal is nearly complete in 7 days. L. E. Gilson

Intestinal secretion during anoxia. David W. Northup and Edward J. Van Liere. *Proc. Soc. Exptl. Biol. Med.* **42**, 162–3(1939).—Decrease in atm. O_2 tension to 53 mm. Hg (equiv. to altitude 28,000 ft.) had no significant effect on secretion of succus entericus in dogs. This indicates a low energy requirement for intestinal secretion. L. E. Gilson

The diffusible organic blood-clotting factor. Anthony J. Glazko and David M. Greenberg. *Proc. Soc. Exptl. Biol. Med.* **42**, 177–8(1939).—The factor (cf. Larson and Greenberg, *C. A.* **30**, 5636[1]) is thermolabile. It acts as a thromboplastin in accelerating coagulation. L. E. G.

Further evidence for a mammogenic factor in the rat hypophysis. Ralph P. Reece and Samuel L. Leonard. *Proc. Soc. Exptl. Biol. Med.* **42**, 200–2(1939); cf. *C. A.* **32**, 5462[3].—In rats of both sexes the hypophysis contains a factor capable of inducing growth of the mammary glands in castrated hypophysectomized immature female rats. The administration of estrogens does not influence this "mammogenic factor" when tested on hypophysectomized rats. L. E. Gilson

Reduction of dehydroascorbic acid in the stomach and small intestine. C. J. Harrer, M. O. Schultze and C. G. King. *Proc. Soc. Exptl. Biol. Med.* **42**, 233–6(1939).—No reduction, absorption or decompn. was detected in the guinea-pig stomach. In the small intestine reduction and absorption proceeded rapidly. L. E. Gilson

Tests of mammalian gonad-stimulating hormones on gonads of fishes. Mychyle W. Johnson and Oscar Riddle. *Proc. Soc. Exptl. Biol. Med.* **42**, 260–2(1939).—Gonad-stimulating hormone from beef hypophyses, powd. dried pregnant mare serum and com. human pregnancy urine ext. known to be potent were injected daily for 21 or 15 days into immature rainbow trout aged 11 or 16 months. No measurable stimulation of either testes or ovaries was found. The gonad-stimulating hormone elaborated by fish hypophyses probably differs from that of mammals. L. E. Gilson

Andromimetic effect of estrogen on the clitoris of the rat. C. Donnell Turner and W. L. Burkhardt. *Proc. Soc. Exptl. Biol. Med.* **42**, 267–70(1939). L. E. Gilson

Cholinesterase activity in various portions of the rabbit heart. Wm. Antopol, Susi Glaubach and David Glick. *Proc. Soc. Exptl. Biol. Med.* **42**, 280–2(1939).—The auricles contained 2–10 times as high a concn. of cholinesterase as the ventricles. L. E. Gilson

Hypersecretion of gonadotropic hormone of rat pituitary resulting from treatment with antigonadotropic serum. Roland K. Meyer and Herbert S. Kupperman. *Proc. Soc. Exptl. Biol. Med.* **42**, 285–8(1939).—Pretreatment of young female rats with antigonadotropic rabbit serum induced a hypersecretion of pituitary gonadotropic hormone, shown by precocious development of the ovaries of the treated rat after discontinuing the injections, and by the ovarian hypertrophy occurring in female rats paired in parabiosis to pretreated male or female littermates. The possible mechanism of the action is discussed. L. E. G.

Site of formation of citric acid in the dog. Arthur H. Smith, James M. Orten, C. G. Johnston and L. C. Bauguess. *Proc. Soc. Exptl. Biol. Med.* **42**, 288–91 (1939); cf. *C. A.* **33**, 3857[8].—Na *dl*-malate was injected into the artery of the exteriorized dog kidney. No conversion to citric acid by the kidney was detected. L. E. Gilson

Uterine effects from single treatments of stilbestrol and ethinylestradiol in monkeys (Macacus rhesus). Earl T. Engle and Roger C. Crafts. *Proc. Soc. Exptl. Biol. Med.* **42**, 293–6(1939); cf. *C. A.* **33**, 7385[7].—In adult ovariectomized monkeys uterine bleeding occurred in 11–28 days after a single oral or intramuscular dose of 1–200 mg. diethylstilbestrol. Oral doses exert as prolonged estrogenic action as intramuscular injections and 5–10 mg. doses are as effective as 100–200 mg. After oral doses of 0.5 mg. ethinylestradiol uterine bleeding occurred on days 18–20. No toxic effects were observed in any of the expts. L. E. Gilson

The pH of normal conjunctival sac secretion determined by the glass electrode. K. C. Swan, R. E. Trussell and J. H. Allen. *Proc. Soc. Exptl. Biol. Med.* **42**, 296–8 (1939).—The pH of normal human lachrymal fluid is 7.17–7.42, av. 7.32. Stimulation increases the flow and raises the pH to 7.5–7.9. L. E. Gilson 1

Effect of adrenalectomy on fat absorption measured by fat excretion in the stool. Wm. G. Clark and Arne N. Wick. *Proc. Soc. Exptl. Biol. Med.* **42**, 336–8(1939); cf. *C. A.* **33**, 8258⁴.—With adequate food and NaCl intake, removal of the adrenals does not affect the excretion of fat in the feces of rats. L. E. Gilson 2

Effect of heterologous antigonadotropic serums on the course of pregnancy in rats. B. Zondek, A. Hochman and F. Sulman. *Proc. Soc. Exptl. Biol. Med.* **42**, 338–41 (1939).—Large amts. of antigonadotropic serums (goat) active against human pregnancy urine prolan and human hypophyseal prolysan were injected daily in rats. This did not interfere with the normal cycle or with impregnation, nidation, delivery and normal breeding. Species specificity is indicated. L. E. Gilson 3

Does the antigonadotropic factor occur in the organism under physiological and pathological conditions? Bernhard Zondek and Felix Sulman. *Proc. Soc. Exptl. Biol. Med.* **42**, 342–5(1939).—Expts. indicate that no antiprolan is produced in the human organism during pregnancy. No antiprolan has been found in individual organs or blood of normal, amenorrhoic or sterile women or of patients with tumors. Antiprolan is elaborated in the animal organism, as a protective mechanism, after a type of prolan foreign to the species has been administered. L. E. Gilson 4

Mechanism of lipoid excretion through the enteric mucosa. G. Liguori. *Boll. soc. ital. biol. sper.* **14**, 445–6 (1939). Helen Lee Gruehl 5

Physiological variations of blood cholesterol with age. Bruno Manca. *Boll. soc. ital. biol. sper.* **14**, 446–7(1939).—In guinea pigs there was a slow and gradual increase in blood cholesterol titer with increased age. H. L. G.

Utilization of lactic acid by eviscerated dogs. L. Milla and V. Capraro. *Boll. soc. ital. biol. sper.* **14**, 469–71 (1939).—The liver was found of little importance in the lactic acid cycle in the organism. Helen Lee Gruehl

Estrogenic substances in the gastric juice. G. Michetti and G. Beltrami. *Boll. soc. ital. biol. sper.* **14**, 513–14 (1939).—No estrogenic substances were demonstrable in the gastric juice of 10 women in advanced pregnancy. Helen Lee Gruehl

The fat-soluble pigment of the cow colostrum and its behavior during the colostral period. Fridolin Richter *Kuhn-Arch.* **49**, 269–90(1938).—The amt. of fat-sol. pigment (principally carotene) in the colostrum and colostral fat depends chiefly on the time of year as well as on the feeding. There appears to be no correlation between the fat and pigment contents of either the colostral fat or milk. The pigment content decreases logarithmically as the colostrum is transformed into mature milk. A direct relationship exists between the I content and the amt. of pigment in the colostral milk. 127 references. C. K. Horner 7

The pH of the contents of the digestive canal of the equine. E. E. Leasure, R. P. Link and J. H. Whitlock. *Cornell Vet.* **29**, 362–6(1939).—The detns. were made on numerous horses, 10 or more years of age, within 8–20 min. after they were slaughtered. The av. pH values were: stomach 4.458, duodenum 7.130, jejunum 7.467, ileum 7.548, cecum 7.235, large colon 7.09 and rectum 6.24. The range of pH varied within wide limits in animals that were assumed to be normal. The values were considerably higher when the contents of the gut contained large quantities of catarrhal or mucilaginous exudate. K. D. Jacob 8

The hydrogen-ion concentration of vaginal secretions of cows. S. H. McNutt, L. H. Schwarte and D. F. Eveleth. *Cornell Vet.* **29**, 415–19(1939).—The limited data indicate that the pH is likely to be at or above 7.0 during estrus but that, in general, the pH of the secretions is not of much significance for diagnostic purposes in diseases connected with breeding. K. D. Jacob 9

The method of direct action on the central nervous system, and more particularly on the vegetative cerebral centers. L. S. Shtern. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 267–70(1939)(in French).—One of the determining factors of the functional state of the vegetative nervous centers of the brain is the K/Ca ratio. Increase of the ratio by direct injection of an ext. of the posterior lobe of the hypophysis, adrenaline or K salts into the cerebral ventricles results in excitation of the nervous centers, while decrease of the ratio by the injection of kidney extract or Ca salts results in inhibition. Shock is accompanied by a decrease in K and inorg. P and an increase in Ca, and can be relieved by direct injection of K and P salts. Injection of the salts into the blood stream is not always effective because of the resistance of the hematoencephalic barrier. S. A. Karjala

The influence of brain metabolites on the secretory and motor functions of the stomach. K. A. Guerchikova. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 315–18(1939) (in French).—The intravenous injection of small concns. of the protein-free ultrafiltrates of brain metabolites into dogs causes an increase in gastric juice secretion, an increase in total acidity and free HCl, and a decrease in digestive capacity. Large doses decrease the secretion of gastric juice but have no effect on total acidity, free HCl or digestive capacity. In all cases gastric secretion was obtained only with the simultaneous administration of milk as a stimulant. Depending upon the functional state of the motor app. of the stomach, injection of brain metabolite solns. may increase or decrease motor activity. If the stomach is in a state of relative rest the injections increase the activity, but if it is at max. activity they decrease activity. S. A. Karjala

The influence of brain metabolites on the oxidation process of animal tissues. E. Govorovich and M. Tikhaya. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 339–43(1939) (in French).—There are no differences in the action of brain metabolites isolated during rest or during induction coil excitation on the respiration of the brain, kidney liver or muscles of cats. S. A. Karjala

The oxidation-reduction potential of the blood. I. A. Givin. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 344–8(1939) (in English). The symbol E_H is more satisfactory for the oxidation-reduction potential than E_S (cf. Serezhskiĭ and Schneerson, C. A. **33**, 2579⁹) since it refers the potential to the normal H electrode and is also not limited to the blood potential. Attempts to obtain E_H *in vivo* give more neg. results than *in vitro* since the value obtained is the sum of the potentials of the blood and the tissues directly in contact with the electrodes, and the E_H of tissue is more neg. than that of blood. The E_H of blood in a syringe electrode or under paraffin oil reaches a steady value of 205–220 mv. in 3–15 min. and not in 1.5 hrs. as stated by Serezhskiĭ (*C. A.* **33**, 2580⁹). Pt and Ir-Pt electrodes give stable values in 5–10 min. while the Hg electrode reaches a steady value, 5% higher than that of Pt, only in 25–35 min. Pt syringe needles give steady values in 10 min. but they are 10% high. Au-plating of Pt and Ir-Pt electrodes does not change the E_H, while Au-plating of Pt syringe needle electrodes reduces E_H, to the normal for Pt. Cu electrodes give an E_H of 60 mv. for blood, while Au-plating of Cu causes a rise in E_H to 160 mv. Microscopic examn., however, of the Au-Cu electrode indicated an uneven Au layer, and the above value may be a result of exposed Cu. The E_H of the blood is a very inert value which is changed only by extremely serious disturbances in oxidative processes. The lability of the potential described by S. and S. was not confirmed. S. A. Karjala 6

Morphology of glycogen distribution and transformation. III. Cytology of glycogen accumulation in the motor cells of the normal nervous system. A. L. Shabadash. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 353–7(1939) (in English); cf. *C. A.* **33**, 6373⁵.—The normal resting or recently recovered nerve cell contains glycogen (I), although variations in carbohydrate metabolism from one

kind of nerve cell to another gives rise to many types of I accumulation. All the motor cells of a definite level of the motor nucleus show the same typical degree of I accumulation at the same time. The granules of "normal" I are characteristic and readily distinguished from pathol. I inclusions which appear as large coarse structureless deposits which distort the shape of the cells. I is found as a normal component of the Nissl tigroid, where it is probably combined with protein. **IV. Glycogen in the cells of the gasserian and spinal ganglions of normal animals.** R. V. Reentovich and A. L. Shabadash. *Ibid.* 8, 29–31.—The normal, pseudounipolar nerve cells of the gasserian and spinal ganglions of mammals in a relatively quiescent state and under proper conditions of nutrition contain glycogen. S. A. Karjala

The correlation between the ovary and the cortical substance of the adrenal gland. M. Solovei. *Bull. biol. méd. exptl. U. R. S. S.* 7, 358–60(1939)(in English).—Foxes were given 5 injections of 200–280 mouse units of prolan (I) on alternate days, starting immediately after exptl. estrus. Dissections on the 1st and 3rd days after beginning the injections of I showed the ovaries contained follicles in various stages of luteinization, with large accumulations of lipoids in the cortical substance of the adrenals. Foxes dissected on the 5th and 7th days after injection of I contained large follicles strongly distended with follicular fluid (cystiform follicles). A slight increase in the amt. of lipoids in the cortical substance was observed. Foxes dissected on the 9th day showed a much reduced liberation of lipoids and indicated that I affects the activity of the adrenal glands indirectly through the sex glands. S. A. Karjala

The condition of potassium within the erythrocytes. B. N. Tarusov and E. V. Burlakova. *Bull. biol. méd. exptl. U. R. S. S.* 7, 400–1(1939)(in English).—Hemolysis of rabbit blood by dil'n. with 20% of H_2O does not change the elec. cond. nor increase the amt. of unbound K. Hemolysis with saponin causes a drop in the polarization capacity of the blood and increases the K content of the serum from 19 to 23 mg. % to 65–95 mg. %. Thus it is not the cellular membrane which prevents escape of K from the cell, and K does not exist as the free ion in the cell, but is undoubtedly combined with cell proteins. S. A. Karjala

The gonadotropic activity of the anterior pituitary of cow embryos. L. N. Daineko. *Bull. biol. méd. exptl. U. R. S. S.* 7, 422–5(1939)(in English).—The amt. of gonadotropic hormone per g. of anterior pituitary in cow embryos of approx. ages 3, 3.5, 3.5–6.0, 6.0–6.5, 6.5–7.5, 7.5 and 8–9 months and in full-grown cows is 16, 50, 40, 50, 100, 330, 200 and 100 mouse units, resp. No traces of the hormone were detected in other embryonic tissues in biol. tests. S. A. Karjala

The effects of the products of nervous stimulation upon phagocytosis. G. G. Golodets and N. Pushkov. *Bull. biol. méd. exptl. U. R. S. S.* 7, 436–9(1939)(in English).—The perfusate of an isolated frog leg, collected during stimulation of the sympathetic nervous system with an induction coil, when added to a suspension of leucocytes in Ringer soln., caused an increase of 6–15% in the phagocytizing power of the leucocytes. S. A. Karjala

The oxidation process in the organism at various ages. (Carbon, nitrogen, and the carbon-nitrogen ratio in the urine.) S. N. Sinitsyn. *Bull. biol. méd. exptl. U. R. S. S.* 7, 444–7(1939)(in German).—The C and N elimination in g. and the av. C/N ratio of the urine of 2.5–6 months, 0.5–1 yr., full-grown and 15–17-yr.-old dogs are 0.38–1.26, 0.72–2.20 and 0.60, 1.08–2.48, 1.44–3.84 and 0.67, 1.92–4.30, 2.40–5.70 and 0.80, and 3.52–6.00, 2.71–5.60 and 1.13, resp. The same values for the urine of human beings in the age groups 6–10, 10–14, 14–19, 30–60 and 60–97 were 1.62–5.71, 2.23–8.7 and 0.69, 4.07–7.05, 5.75–10.33 and 0.70, 5.15–8.1, 6.25–11.33 and 0.75, 7.26–12.0, 10.36–13.5 and 0.85, and 5.7–18.25, 5.2–13.9 and 1.29, resp. S. A. Karjala

Ontogenetic changes in cholinesterase activity in the skeletal muscles of rabbits. Rachael Leibson. *Bull. biol. méd exptl. U. R. S. S.* 7, 514–17(1939)(in English).—The femoral muscles of embryonic and newborn rabbits, and small portions of the muscles of adult rabbits were treated with acetylcholine (I) solns. of known concn. and the time necessary to split 50% of I was detd. The muscles of rabbits on the 24–25th day of embryonic life split 50% of I in 2 min., those of newborn rabbits in 30–40 sec., while the enzyme extd. from adult muscles required 12–20 min. The cholinesterase (II) content of the muscles of young rabbits reaches the level characteristic of adult rabbits only in 2 months. It is suggested that the curve thus obtained of the activity of II plotted against age is a product of 2 curves, one curve slowly increasing until the 10th day after birth and then leveling off, representing the increase in the content of II, and a rapidly decreasing curve leveling off about the 30th day after birth, representing the diminution in mass of the "receptive substance" into which II concentrates. S. A. Karjala

The effect of denervation on the cholinesterase content of the skeletal muscles of rabbits. Rachael Leibson. *Bull. biol. méd. exptl. U. R. S. S.* 7, 518–20(1939)(in English).—The cholinesterase content of the muscles of rabbits falls to 60% of normal 6 days after denervation of the muscle. It then begins to rise, and in 3 weeks is at the level found in embryonic tissue, and in 2 months is 20–25 times the normal. S. A. Karjala

The reciprocally contradictory interaction of the thyreotropic function of the hypophysis and thyroid. M. M. Zavadovskiĭ and E. I. Vorob'ev. *Bull. biol. méd. exptl. U. R. S. S.* 7, 524–7(1939)(in English).—The feeding of male rats with thyroid prepns. causes a decrease in the wt. and function of the thyroids of the exptl. animals. S. A. Karjala

The reciprocally contradictory interaction of the gonadotropic function of the hypophysis and genital glands. I. The decrease in gonadotropic activity of the hypophysis after the administration of a gonadotropic agent. M. M. Zavadovskiĭ and T. A. Lipgart. *Bull. biol. méd. exptl. U. R. S. S.* 7, 528–32(1939)(in English).—The injection of the serum of pregnant mares into rats as a gonadotropic agent results in a decrease in the gonadotropic activity of the hypophysis. **II. Is the influence of the serum of pregnant mares or of prolan on the hypophysis accomplished through the genital glands or in other ways?** *Ibid.* 533–6.—The injection of the serum of pregnant mares into castrated infantile female or adult male rats causes little or no decrease in the gonadotropic activity of the hypophysis. S. A. Karjala

Transient weakening of organ function caused by the administration of homonymous organotherapeutic preparations and the dynamics of this phenomenon. M. M. Zavadovskiĭ. *Bull. biol. méd. exptl. U. R. S. S.* 7, 537–9(1939)(in English).—A review of the available data showing that the injection of any organotherapeutic prepn. results in a temporary inhibition of the activity of the gland responsible for excretion of the organotherapeutic agent. S. A. Karjala

The gonadotropic function of the hypophysis of pregnant women. Does the hypophysis of pregnant women contain a luteinizing factor? P. A. Wunder and K. H. Wiebe. *Bull. biol. méd. exptl. U. R. S. S.* 7, 540–3(1939)(in English).—Combinations of the hypophysis of pregnant women with that of nonpregnant women and with the gonadotropic hormone obtained from the serum of pregnant mares do not show an increase in the gonadotropic reaction. While a dose of 0.1 mg. of the hypophysis of nonpregnant women produces estrus in 92.4%, combination with that of pregnant women produces estrus only in 47% of the cases. No evidence was found to support the suggestion that the hypophysis of pregnant women is rich in a luteinizing factor. S. A. K.

The permeability of the placenta to the thyroid and thyreotropic hormones. S. Theresa. *Bull. biol. méd. exptl. U. R. S. S.* 7, 544–8(1939)(in French).—The thyroid and thyreotropic hormones of the hypophysis permeate the placenta and activate the thyroid gland of the embryo. S. A. Karjala

The quality of the catalase of the rabbit embryo in the course of its development. A. V. Vadova. *Bull. biol.*

méd. exptl. U. R. S. S. **7**, 554–6(1939)(in English).—The velocity const. $Q_{10} = K_{20}/K_{10}$ and activation energy E_A of the decompn. of H_2O_2 by the catalase of the embryonic tissues of rabbits are const. during the interval 18–30 days growth of the embryo and average 1.53 and 7000 cal. The Q_{10} and E_A of H_2O_2 decompn. by the muscle tissue of pregnant females 20 and 30 days after pregnancy are 2.22 and 13,000 cal. and 1.9 and 11,000 cal., resp., while embryonic tissue at 20 and 30 days gives the values 1.51 and 7000 cal. and 1.57 and 7300 cal., resp. The same values for the muscle tissue of newborn rabbits are 1.06 and 900 cal. S. A. Karjala

The cholinesterase content of embryonic muscles. N. M. Shamarina. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 67–9(1939)(in English).—An ext. of the auricles of adult rabbits required 40 min. to decomp. 80% of the acetylcholine in a soln. of known concn., while that of the auricles of embryonic rabbits on the 24th day of growth required 120 min. No cholinesterase (I) activity was observed before the 18th day of embryonic life. On the 28–30th day of the embryo the concn. of I in the auricles is slightly lower than that in adult auricles. Immediately after birth the value falls to a min. on the 4–6th day after birth, followed by a rise to the value found in adult auricles on the 9–10th day after birth. S. A. Karjala

Cholesterol formation in muscle. D. E. Yankelevich. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 77–80(1939)(in English).—Of 228 detns. of the cholesterol (I) content of the arterial and venous blood of the hind leg, lumbar and tongue muscles of dogs, no difference was found in 59 cases, in 31 cases an av. of 7 mg. % of I was retained by the muscles and in 138 cases an av. of 7.35 mg. % of I was liberated in the blood stream. S. A. Karjala

Gastric juice amylase. A. I. Tumass. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 89–91(1939)(in English).—The elimination or weakening of the nervous connections of the stomach and their subordination to humoral influences in regulating the action of the stomach causes the appearance of amylase (I) in the gastric juice. Transplanted stomachs, whose regulative mechanism is controlled mainly by humoral factors, gives the highest value of I, while the Heidenhain pouch and isolated pylorus, in which the nervous connections are through the sympathetic fibers, are rather low in I. S. A. Karjala

The liberation of glucolytic enzyme by the mucosa of the pyloric part of the stomach. A. I. Tumass. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 92–4(1939)(in English).—The gastric juice secreted by the isolated pylorus of dogs after feeding meat, bread or milk contains a glucolytic enzyme capable of splitting glycogen with the formation of lactic acid. S. A. Karjala

Aneurin and phosphorus compounds of blood. Gilberto Guimarães Villela. *Z. physiol. Chem.* **261**, 20–3 (1939).—Aneurin (I) (1 mg.) added to blood (5 cc.) *in vitro* causes the acid-sol. P to increase and the lipoid P to decrease. The same changes are observed *in vivo* on injection of 10 mg. of I but they are transitory. It is believed that I activates corpuscle phosphatase. Repeated I dosage (14 to 16 mg. in 4 days) in rabbits leads to a decrease in blood pyrophosphate, probably through utilization for tissue fixation of I. Milton Levy

Occurrence and properties of the lactation hormone. E. Rabald and H. E. Voss. *Z. physiol. Chem.* **261**, 71–81 (1939).—Livers from healthy cattle and swine contain a substance with chem. and biol. properties very similar to prolactin from the anterior pituitary. While the concn. is lower, the amt. obtainable per animal is much greater from liver than from pituitary. To prep. prolactin from liver, ext. 20 kg. of ground liver with 30 l. of 70% EtOH at pH 9.5, filter and bring the filtrate to pH 5.5–6, increase the EtOH concn. to 90% and cool well for 24 hrs. Dissolve the centrifuged ppt. in H_2O at pH 9.5 and adjust to 5.5–6. Centrifuge and wash the active ppt. with 96% EtOH and 100% Me_2CO. It can be purified by soln. in glacial HOAc and after removal of the insol. material, pptn. with 10–20 vols. of Et_2O. The substance contains N 3.7, C 47, H 6.9 and ash 2%, and shows all the reactions for proteins except those for tryptophan. All these figures and reactions are similar to those of prolactin from pituitary. The activity of the best liver prepn. is only 0.05 that of the pituitary material. Milton Levy

Composition of the blood of horses as related to their working capacity. Kh. F. Kushner. *Bull. acad. sci. U. R. S. S., Sér. biol.* **1939**, 103–16(in English, 116); cf. *C. A.* **33**, 8262⁹.—The chief constituents of the blood responsible for its oxidizing functions (no. of erythrocytes, hemoglobin content and blood alky.) show the highest indexes in race horses, then in cavalry horses, next in trotters and, least of all, in draft horses. These differences are correlated with the character of the phys. labor ordinarily performed by animals of the 4 types. 47 references. John Livak

The free choline and phospholipide of hepatic and gallbladder bile. Chas. G. Johnston, J. Logan Irvin and Clarence Walton. *J. Biol. Chem.* **131**, 425–37(1939).—Only small amts. of free choline are present in fresh hepatic and gallbladder bile of human beings, dogs and hogs but they contain large amts. of combined choline. On standing in an icebox the choline compd. decomps. rapidly with the formation of free choline even in the presence of C_7H_8 and $CHCl_3$. Vacuum sublimation of H_2O from frozen hog gallbladder bile causes decompn. of most of the combined choline compd. The presence of the free choline in this dried bile may account for part of its stimulatory effect on the gastrointestinal tract. A portion of the combined choline, which is a phospholipide having a mole ratio of choline to P of 1:1, may be extd. with Et_2O-alc. mixts. The isolation of lecithin from this fraction is a finding not in agreement with the report of Jones and Sherberg (*C. A.* **31**, 3114¹) that lecithin is either entirely absent from dog and hog bile or is present only in traces. The possibility of the presence also of sphingomyelin or some other phospholipide with the same choline:P ratio has not been excluded. **The comparison of desiccated and normal hog gallbladder bile.** J. L. Irvin, Harvey Merker, Carl E. Anderson and C. G. Johnston. *Ibid.* 439–45.—After desiccation of fresh hog gallbladder bile by a vacuum process, no significant changes are found in the chem. and phys. characteristics except that free choline increases and the phospholipide correspondingly decreases. The dried bile is quite sol. in H_2O, giving a soln. similar to normal bile. A. P. Lothrop

The red blood cell as a source of the iron and bilirubin of the blood plasma. Georg Barkan and Burnham S. Walker. *J. Biol. Chem.* **131**, 447–54(1939); cf. *C. A.* **21**, 3942.—Simultaneous transfer of Fe and bilirubin from red cells to plasma occurs *in vitro*, the amts. transferred being of the same order of magnitude, with Fe usually being in slight excess. The rate of transfer is variable but the rates are inadequate to account for more than a small fraction of the daily production of bile pigment. The main portion of bile pigment appears to be formed elsewhere than in circulating blood and it seems logical to proceed on the working hypothesis that in general the pseudohemoglobins of Barkan and Schales (*C. A.* **32**, 5890⁹)—compds. in which the porphyrin ring is opened without loss of Fe or denaturation or sepn. of the globin—are the intermediate products between hemoglobin and bilirubin, regardless of the place in which the degradation occurs. There is no evidence that the conversion results from the action of an enzyme (cf. Czike, *C. A.* **24**, 3545). A. P. Lothrop

The excretion of kynurenic acid by members of various families of the order Carnivora. Richard W. Jackson. *J. Biol. Chem.* **131**, 469–78(1939); cf. *C. A.* **30**, 2589³.—After the administration of tryptophan, kynurenic acid was excreted by the hyena, coyote, wolf, fox and badger and not by the serval, cheetah, civet, genet, bear, raccoon and sea lion. The data, insofar as they deal with more than 1 species of 1 family, are compatible with the hypothesis that the excretion of kynurenic acid or its failure to be excreted may be entirely uniform for each family of the Carnivora. A. P. Lothrop

Comparative studies of the metabolism of the amino acids. VIII. Glycine precursors. Availability of *N*-methylglycine, *N*,*N*-dimethylglycine and betaine for the syn-

thesis of hippuric acid by the rabbit. Lynn DeForrest Abbott, Jr., and Howard B. Lewis. *J. Biol. Chem.* **131**, 479-87(1939); cf. *C. A.* **17**, 3695.—*N*-Methylglycine (sarcosine) increases the rate of excretion of hippuric acid when fed to a rabbit along with BzOH but the effect is not as great as that of glycine. There is no formation of methylhippuric acid. *N,N*-Dimethylglycine and betaine do not increase hippuric acid excretion under the same conditions. This utilization of sarcosine in the detoxication mechanism is interpreted as evidence of the biol. conversion of sarcosine to glycine. A. P. L.

Choline metabolism. I. The occurrence and prevention of hemorrhagic degeneration in young rats on a low-choline diet. Wendell H. Griffith and Nelson J. Wade. *J. Biol. Chem.* **131**, 567-77(1939); cf. *C. A.* **33**, 8247[2].—A choline deficiency can be produced in white rats within 10 days on a low-choline diet and is characterized by an extremely toxic state during which there occurs a marked hemorrhagic degeneration of the kidneys, a regression of the thymus and an enlargement of the spleen. The renal lesions can be prevented by amts. of choline which are insufficient for the prevention of fatty livers. These findings demonstrate that choline has a more fundamental role as a dietary essential than its function in the regulation of the fat and cholesterol content of tissues, particularly of the liver. The requirement for choline was found to be greater in young than in older rats.
A. P. Lothrop

The creatine, phosphorus and collagen content of different sections of the dog heart. Harvey E. Alburn and Victor C. Myers. *J. Biol. Chem.* **131**, 713-16(1939).—Analyses of samples from 7 different areas of 8 dog hearts for creatine, total inorg., total acid-sol., and total P and of 2 hearts for collagen N showed the concns. of all these to be quite uniform within the individual ventricles. The left ventricle averaged 7.3% higher in creatine and 9.7, 11.0 and 8.4% higher, resp., in the 3 P fractions. The right ventricle contained 8.2% more collagen N.
A. P. Lothrop

The curves of buffer coefficients of serum. Madeleine Gex. *Bull. acad. med.* **121**, 525-9(1939).—The structure of buffer coeff. bands of serum between pH 5 and 9 is detd. by 2 factors: (1) the presence of certain dissociable electrolytes, 2 of which have been identified as bicarbonates and phosphates, and others of pK 5 (8), 7.6 and 8 (2) and (2) a phenomenon of phys.-chem. disturbance caused by changes in the colloidal structure of the serum and depending on the position of the isoelec. points.
A. E. Meyer

Blood content of inactive hemoglobin with special consideration of hemoglobin standardization. Esther Ammundsen and Mogens Trier. *Acta Med. Scand.* **101**, 451-60(1939).—The hemoglobin detns. by the gasometric and colorimetric methods do not yield concordant results, the max. discrepancy being 13%. In certain persons an inactive fraction was found to be present in the hemoglobin which can combine with CO only after preliminary reduction with $Na_2S_2O_4$. If this inactive fraction is taken into consideration, the max. difference between the gasometric and colorimetric hemoglobin detns. is diminished to only 6%. It is, therefore, recommended to substitute the CO-combining power for the O_2-binding power in standardizing colorimetric hemoglobinometers.
S. Morgulis

An electrophoretic study of normal and pathological body fluids. Lennart Hesselvik. *Acta Med. Scand.* **101**, 461-4(1939).—The proteins of serum can be sepd. into 4 components as regards electrophoretic motility, the fastest migrating component being albumin and the slower α, β and γ globulins, resp. In plasma a fifth component, apparently fibrinogen, was found migrating between α- and β-globulin. An examn. of a variety of body fluids (urine, pleural effusion, aqueous humor, or pericardial, cerebrospinal, ascites and hydrocele fluids) reveals the presence of electrophoretically well-defined protein components, but here only 3 and sometimes even 2 distinct boundaries are regularly found. It is possible that the missing components were merely at too low a concn. to be detected.
S. Morgulis

Studies on the influence of vomiting and nausea upon the renal function. Johs. Clausen. *Acta Med. Scand.* **102**, 22-30(1939).—Nausea and vomiting, apart from decreasing diuresis, cause a marked fall in the urea and creatinine clearance. Since the urea clearance is affected more, the urea clearance/creatinine clearance ratio diminishes. This can only be due to an increased reabsorption of urea in the tubules. This study indicates the limitations of the kidney-function tests in the presence of vomiting or nausea.
S. Morgulis

Studies in sulfate clearance. Tage Bjering and Ejnar Øllgaard. *Acta Med. Scand.* **102**, 55-78(1939).—The sulfate clearance in normal persons was found to be 37 cc. on the av., but is generally less in persons affected by kidney disease. The diminished clearance corresponds to the decrease in creatinine or in urea clearance, except in patients with amyloid kidney degeneration where the urea clearance decreases more than the sulfate clearance. About 0.8 to 0.9 mg. of blood sulfate is probably in combination with protein as it does not go through the glomerulus, and this is the same in healthy or diseased persons. On the administration of sulfate the clearance increases up to a const. value which falls between the urea and creatinine clearances. After correcting for the nonfilterable portion of blood sulfate, the sulfate clearance is about the same as that of inulin, the creatinine/sulfate and creatinine/inulin ratios both being about 1.4. The urea/sulfate ratio is 0.73-0.74. The similarity of the inulin and sulfate clearances indicate that the sulfate may be taken as a measure of filtration.
S. Morgulis

A pharmacognostical study of the parathyroid. I. Heber W. Youngken. *J. Am. Pharm. Assoc.* **28**, 638-43 (1939).—A description is given of the whole fresh and desiccated parathyroid glands of cattle, of their histology and the appearance of the cells after treatment with various stains. Several qual. colored tests for powd. parathyroid and thyroid are described.
A. P.-C.

The catabolism of fatty acids by the living organism. P. E. Verkade. *Fette u. Seifen* **46**, 521-9(1939).—Review of the literature on the reaction mechanism of the progressive oxidation of fats in animal tissues. Attention is devoted to the effect of chem. structure, viz., no. of C atoms in the fatty acid, presence and position of unsatd. linkages and form of combination of the fatty acid. Over 70 references.
J. W. Perry

The effect of gastric mucin on the hemoglobin regeneration in anemic dogs. H. S. Wigodsky, R. A. Bussabarger and S. J. Fogelson. *J. Lab. Clin. Med.* **25**, 13-18(1939).—The procedure employed was essentially that of Whipple and Robscheit-Robbins (*C. A.* **30**, 5634[9]). In each of 2 series of 4 anemic dogs mucin stimulated hemoglobin production 55 to 70% more than could be accounted for by the amt. of Fe present in the prepn. The stimulus was not as great as when beef liver was fed. Whipple's method (*loc. cit*) of calcn. of hemoglobin formation and one devised by the authors were compared. Conclusion: The procedure of Whipple for detg. the effect of substances on hemoglobin regeneration in anemic dogs is only a qual. rather than a quant. one, unless sufficient data are obtained to permit statistical analysis.
H. W. R.

The absence of acute effects of sex hormones. Macdonald Dick and Charles W. Hooker. *J. Lab. Clin. Med.* **25**, 33-4(1939).—Intravenous administration of 50 mg. of testosterone propionate, 50,000 I. U. of estradiol benzoate, or 400 I. U. of theelin to male and female dogs, both castrated and intact, under morphine-sodium barbital anesthesia produced no change in respiration, heart rate or blood pressure.
Howard W. Robinson

Treatment of hypogenitalism in the male with the gonadotropic principle of pregnant mare serum. Ralph H. Kunstadter. *Endocrinology* **25**, 661-9(1939).—Intramuscular administration of pregnant mare serum gave definite improvement in boys with hypogenitalism.
Felix Saunders

Comparison of four methods of bioassay for the gonadotropic factors. Robert T. Frank and Rose L. Berman.

Endocrinology **25**, 683–8(1939).—The follicle-stimulating factor is concd. by all the methods currently employed. Luteinization effect is lost or greatly diminished except by the Me_2CO or acid alc. method of concn. The acid alc. method of concn. gives a more complete evaluation of conditions present. Vaginal opening is unreliable for bioassay. Ovarian wt. increase indicates the amt. of follicle-stimulating factor present but does not permit evaluation of the luteinizing factor. Ovarian values appear to give the most comprehensive picture of the gonadotropic forces at work. Felix Saunders

Hyperfunction of the anterior pituitary in a strain of rats. Ben K. Harned and Versa V. Cole. *Endocrinology* **25**, 689–97(1939).—Rats of the Yale and Wistar strains grown on the same diet and under the same conditions for 3 generations were compared. The Yale rats show a higher fasting blood sugar, a lower glucose tolerance, a greater hyperglucemic response to adrenaline, an initial resistance to insulin, a larger vol. of urine per unit of body wt., a more rapid growth and larger size, a greater incidence of sterility and a higher percentage of body fat. These findings can be explained by the assumption of a hyperfunction of the anterior pituitary in the Yale rats. Felix Saunders

Behavior and antomical changes produced in rats by pancreatectomy. Curt P. Richter and Edward C. H. Schmidt, Jr. *Endocrinology* **25**, 698–706(1939).—Loss of pancreatic secretion results in reduced food intake which leads to atrophy of the endocrine glands. Felix Saunders

Antithyroid principles. Julius Bauer, Wm. G. Fisher and Geo. Gutman. *Endocrinology* **25**, 721–3(1939). By the use of a method described a principle antagonistic toward thyroxine has been found in sheep and human serum. Diiodotyrosine, olive oil and theelin do not exhibit such an effect. The method is not appropriate for the detection of thyroid hormone in excess in the blood of hyperthyroid subjects. Felix Saunders

Somatic growth-depressing effect of testosterone propionate. H. S. Rubenstein, A. A. Kurland and M. Goodwin. *Endocrinology* **25**, 724–8(1939).—Testosterone propionate given in doses of 1 mg. intraperitoneally 26–80 days significantly depresses body wt. and length of the male rat. Felix Saunders

Responses of the female to male hormone substances. Behavior of hens and newly hatched chicks. James B. Hamilton and Walter R. C. Golden. *Endocrinology* **25**, 737–48(1939).—Administration of cryst. male hormone substances can produce definite cock-like behavior in either newly hatched female chicks or in the mature hen. Felix Saunders

Colchicine test as a method for determining the time of onset and the duration of action of male active substances. Richard Tislowitz. *Endocrinology* **25**, 749–53(1939).—Colchicine permits a finer analysis of the effect of male hormones on the seminal vesicles than can be obtained by the usual methods in which the enlargement of the whole vesicle is observed. Felix Saunders

Urinary excretion of estrogens, androgens and follicle-stimulating hormone following the administration of testosterone to human female castrates. Ira T. Nathanson and Lois E. Towne. *Endocrinology* **25**, 754–8(1939).—Testosterone propionate when administered to human female castrates results in (*a*) a discernible increase in the urinary total estrogen levels, (*b*) a slight rise in the urinary androgen excretion, (*c*) a decrease in the urinary FSH levels, (*d*) a cornified vaginal smear and (*e*) symptomatic relief from the vasomotor symptoms of the menopause. Felix Saunders

Influence of anterior pituitary extracts on the proteins of the liver. O. Boyd Houchin. *Endocrinology* **25**, 759–67(1939).—Injection of an initial ext. of the anterior lobe of cattle pituitaries (1–20 mg.) does not cause a true hypertrophy of the entire liver. The dehydrated, defatted wt. of the liver per 100 g. body wt. is similar to the normals. The percentage of water in the liver does not vary significantly. The alkali-sol. protein of the liver is decreased 35–53% by a principle (protein-metabolism hormone) present in the anterior pituitary. Acetone-dried prepns. have a slight activity. Fractions of the initial ext. rich in the lactogenic hormone and in the thyrotropic, carbohydrate-metabolism and gonadotropic hormones contain little or no protein-metabolism hormone. The protein-metabolism hormone was further shown to be an entity by its being inactivated by 0.1 *N* NaOH at 60° for 90 min., while the potency of the fat-metabolism hormone remained const. Felix Saunders

Effect of pituitary extracts on ketonuria, fat content and fat distribution in the liver and tissues of mice. A. H. Neufeld and J. B. Collip. *Endocrinology* **25**, 768–74(1939).—In 24-hr. fasted mice active ketogenic prepns. produce a fatty infiltration of the liver. Total body wt. does not change appreciably. In 48-hr. fasted animals the high liver fat is assocd. with a low total body fat. Prepns. contg. the specific metabolic stimulant produce an appreciable loss of total body fat which is assocd. with a low liver fat content in 24-hr. fasted animals. Preliminary expts. on the administration of ketogenic prepns. together with the specific metabolic stimulant show an enhanced loss of total body fat in mice. Felix Saunders

Antagonist to adrenaline hyperglucemia in pituitary extracts. A. H. Neufeld and J. B. Collip. *Endocrinology* **25**, 775–81(1939); cf. *C. A.* **33**, 5904[8]. Certain posterior pituitary prepns. produce, on administration to mice, rats, rabbits, monkeys and a dog, an antagonism to adrenaline hyperglucemia. Numerous properties of the substance are given. The evidence available does not indicate a relationship of this substance to other well-known pituitary principles. Felix Saunders

Effect of androgens on the survival of adrenalectomized rats. Charles L. Spurr and Charles D. Kochakian. *Endocrinology* **25**, 782–6(1939).—The month-old male adrenalectomized rat has an av. survival time of 8.7 days which is decreased to 7.1 days by injecting twice daily with 0.1 cc. of sesame oil. The administration of urinary androgenic ext., androstenedione, testosterone acetate and testosterone propionate resulted in a marked decrease in survival time which was roughly proportional to their physiol. activity. Felix Saunders

Properties of ovarian extracts. H. W. Marlow. *Endocrinology* **25**, 793–7(1939).—The uterine response to exts. of follicular fluid and of the residual ovary resembles more nearly that of estrone than estradiol. Felix Saunders

Use of colchicine in the assay of androgens. Walter Fleischmann. *Endocrinology* **25**, 798–800(1939).—By arresting mitosis with colchicine the stimulating effect of androgens on the seminal vesicle of the castrate rat is sharply defined. A pos. test is given by 0.5 mg. androsterone and by 0.05 mg. testosterone propionate. Felix Saunders

Analysis of the relation between basal metabolism and summated tissue respiration in the rat. John Field, 2nd, Harwood S. Belding and Arthur W. Martin. *J. Cellular Comp. Physiol.* **14**, 143–57(1939).—Basal metabolic rate (BMR) was detd. for postpubertal rats 98–120 days old. No significant correlation between BMR (unit wt. basis) and sex, age or wt. was found. The BMR values (cor. for activity) were 21.3–33.1 l. O, normal temp. and pressure, per kg. body wt. per day, av. 26.36. Mean values of Q_{O_2} were detd. for 20 organs and tissues of these animals. The values were detd. (by extrapolation) at the time of sacrifice of the animal and at various subsequent intervals. A quant. evaluation of the differences in mean Q_{O_2} between the 20 organs and tissues was made. The mean value for summated tissue respiration, calcd. from mean values of Q_{O_2} for the several organs and tissues, was 110.08 ml. O, normal temp. and pressure, per 150 g. rat per hr. or 65.85% of the mean BMR. When the latter value was cor. for min. functional activity, it was found that the summated tissue respiration would account for 89% or more of the respiration of the intact animal. The percentage contribution of the several organs and organ systems to BMR and to body wt. was evaluated. In decreasing order, the 4 most important

contributors to BMR are skeletal muscle, liver, integument and alimentary canal; while the 4 most important contributors to body wt. are skeletal muscle, integument, skeleton and blood. Felix Saunders

Tolerance of chick heart tissues to a time-temperature factor before explantation in tissue culture. Duncan C. Hetherington and Jane Stanley Craig. *J. Cellular Comp. Physiol.* **14**, 197–203(1939).—Survival of chick embryo heart muscle and fibroblasts is dependent upon time-temp. and mass factors. Small fragments of heart may be stored in Ringer-Tyrode soln. at 0° for as long as 15 days and at 20° for 11 days with little apparent effect on viability. Subzero temps. rapidly kill cells as do temps. of 50–52°. Felix Saunders

Presence of nonoxygen-combining (inactive) hemoglobin in the blood of normal individuals. Esther Ammundsen. *Science* **90**, 372 3(1939).—About 3.5% of the hemoglobin from normal persons is in a form that is capable of binding CO only after reduction by Na hyposulfite. Felix Saunders

Essentiality of primary amino groups for specific activity of the lactogenic hormone. Choh Hao Li, Wm. R. Lyons, Miriam E. Simpson and Herbert M. Evans. *Science* **90**, 376–7(1939); cf. *C. A.* **33**, 8269⁸.—A 1.5% soln. of a highly purified lactogenic prepn. was dissolved in 0.5 *M* acetate buffer (pH 4) and treated 30 min. with an equal vol. of 2 *M* $NaNO_2$ at 22° or 0°. The mixt. was then adjusted to pH 5, centrifuged and the ppt. redissolved and repptd. isoelectrically. The crop-stimulating activity of the prepn. was completely destroyed. Felix Saunders

Comparison of chemical composition of hepatoma and normal liver tissues. VIII. Lipoids. Sanzi Kisi, Tadasi Huziwara and Waro Nakahara. *Gann* **33**, 332–41(1939); cf. *C. A.* **33**, 2206².—Cholesterol crystals were isolated from normal rat liver and from transplantable rat hepatoma of Iikubo strain. A comparison of the absorption spectra showed that about $^1/_{15}$ of hepatoma cholesterol crystals consisted of ergosterol or 7-dehydrocholesterol, i. e., provitamin D. Cholesterol, isolated from normal rat liver, did not reveal spectrographically the presence of ergosterol or 7-dehydrocholesterol. K. Sugiura

Specificity of hemoglobins. II. Mituko Yasaki. *J. Chosen Med. Assoc.* **29**, 1657–85(German abstr. 108–9) (1939); cf. *C. A.* **34**, 151⁵. S. Tashiro

Urinary excretion of nephrohormone. Ziro Masuda. *J. Chosen Med. Assoc.* **29**, 1686–708(German abstr. 109–10)(1939).—Normal urine contains an active sterol complex which has the power to change indole to indican, to promote elimination of blood indican, to reduce blood cholesterol and Ca contents, to regulate hyperglucemia, to cause diuresis and to increase blood pressure. This compd. is identical with Tokumitsu's nephrohormone which is present in renal cortex and renal vein. The urinary content of nephrohormone is increased by diuretics. S. Tashiro

Morphology of liver function. II. Relation between liver and kidney fatty degenerations. Syozo Oda. *J. Chosen Med. Assoc.* **29**, 1855–72(German abstr. 116–17) (1939).—Morphological study showing that there is no definite relationship between the 2. S. Tashiro

The effect of the female sex hormone on genital organs of female guinea pigs infected with tuberculosis. I. The sex cycle of tuberculous guinea pigs. Tadahumi Mabuti. *J. Oriental Med.* **31**, 229–40(German abstr. 22)(1939).—The infection of guinea pigs with human tuberculosis bacillus influences the sex cycle. **II. The effect of castration. III. The effect of pelanins.** *Ibid.* 241–67, 269–93 (German abstr. 23–4).—The castration of female guinea pigs increases their resistance to tuberculous infection, and the injection of the ovarian hormone (pelanins) also increases the resistance. S. Tashiro

Enzymic action of human milk. Preliminary. Protein-free filtrate. S. Masutani, S. Okuda, Y. Kuriyama and S. Izumi. *J. Oriental Med.* **31**, 389–63(English abstr. 31–4)(1939).—Protein of free milk (prepd. by the modified Almén method, AcOH and tannic acid instead of gallic acid) of healthy mothers shows amylolytic action; peptic action only with the Fuld and Levison method (cf. *C. A.* **2**, 1156), not with the method of Mett; weak tryptic, lipolytic, catalase, peroxidase but no rennin actions. **I. Optimum reaction of amylolytic action.** S. Masutani. *Ibid.* 539–64(English abstr. 41–2).—The protein-free milk is examd. by Wohlgemuth's starch method (**A**), Izumi and Sonobe's dextrin method (**B**), and Rona and Van Eweyk's glycogen method (**C**), for amylolytic activity. Optimal pH for **A** with the filtrate is 8.0–9.0, but there is a second optimal range at pH 5.9–6.5. With **B**, the optimum is pH 6.5 and with **C**, pH 7.4. The amylolytic activity is shown to be the least with **C**. With **A** and **B**, the reducing sugar is produced but not with **C**. The sides of the nipple and lapses of lactation are not a factor for the variation of amylolytic activity of human milk. S. Tashiro

Vegetative nerves and the alveolar resorption of lung. I. The influence of nerve sections on the alveolar resorption. A. Resorption of dyes. Kiyosi Hurui. *J. Oriental Med.* **31**, 569–601(English abstr. 44)(1939).—A cervicothoracic sympathectomy of rabbits retards the resorption of dyes (Azorubin S, Scarlet R, phenol red and others) in alveoli of the lung, and cervico-vagatomy hastens it. When both nerves are cut, more retardation was shown than in the control, but less as compared to that of animals with sympathectomy alone. S. Tashiro

The mechanism of glycogenolysis. D. Bach. *J. pharm. chim.* **29**, 585–605(1939).—A review. The complicated chem. transformations involved are clearly shown in 2 "flow" diagrams. The remarkable similarity of lactic fermentation of muscle and alc. fermentation of yeast is pointed out; the absence of Neuberg's carboxylase in muscle limits the decompn. of pyruvic acid to lactic acid. S. Waldbott

Inactivation of diethylstilbestrol in the organism. Bernhard Zondek and Felix Sulman. *Nature* **144**, 596–7 (1939).—Expts. with infantile rats indicate that stilbestrol is rendered inactive in the organism only to a small extent, resembling the hormone esters. Like the hormone esters it remains deposited at the site of injection for a considerable time and from there it is slowly absorbed. Stilbestrol is distinguished from the hormone esters in that large amts. are eliminated in the excreta, particularly in the urine. E. D. Walter

Radioactive iron and its excretion in urine, bile and feces. P. F. Hahn, W. F. Bale, R. A. Hettig, M. D. Kamen and G. H. Whipple. *J. Exptl. Med.* **70**, 443–51 (1939).—By use of radioactive Fe as ferrous gluconate it is found that there is an initial extra output in urine and feces during a few days (3–15) after Fe injection by vein and this may total 2–8% of the injected Fe; after this initial reaction the urinary excretion of radio-Fe (I) drops to traces or even to 0. The feces always contains measurable amts. of I—in 5 dogs receiving 100–250 mg. of I the fecal excretion per day settled down to 0.05–0.4 mg. per day. Blood destruction (PhNHAc) causes a definite increase in I eliminated in the feces (0.1–1 mg. per day); probably most of this excess Fe comes through the biliary tract (bile fistula); the bile under usual conditions contributes very little Fe to the intestine (0.01 mg. I per day or less). The body controls its Fe stores by absorption or lack of it rather than by its capacity to eliminate it. The evidence is overwhelming that the dog excretes Fe with difficulty and in small amts. (even in the plethoric state) by means of the biliary and gastrointestinal tracts. C. J. West

Gonadotropic inhibitory substance and precipitins in the blood of monkeys receiving gonadotropic hormone preparations. Roland K. Meyer and Harold R. Wolfe. *J. Immunol.* **37**, 91–102(1939).—The antigonadotropic effect and precipitin titer of the blood of monkeys, which were injected with relatively small amts. of pregnant mare serum having gonadotropic activity, or with a highly purified gonadotropic hormone prepd. from pregnant mare serum, or with the serum of the nonpregnant mare, were detd. The results show that the antigonadotropic substance can be produced by the injection of relatively small amts. of hormone and also indicate that precipitins are not

responsible for the antigonadotropic action of the serums. Charles A. Zittle

Steroids—6-oxoprogesterone (Ehrenstein) 10. Steroids—homologs of sex hormones (Miescher, Wettstein) 10.

G—PATHOLOGY

Recent advances in the chemistry of tumors. P. E. Simola. *Nord. Med.* 3, 2133–9(1939).—A brief review of the progress of chem. cancer research. The following problems are dealt with: (1) chem. constituents and metabolism of tumors, (2) carcinogenesis, (3) diagnosis of cancer and (4) chem.-biol. cancer therapy. Particular attention is given to the studies on cancer-producing chem. compds. and biol. agents. V. Aschehoug

Absorption and excretion of ascorbic acid in patients with pulmonary tuberculosis. B. Groth-Petersen and E. Groth-Petersen. *Nord. Med.* 3, 2141–5(1939).—By use of the methylene-blue method, serum ascorbic acid and urine ascorbic acid were detd. to ascertain why patients with pulmonary tuberculosis show a lower concn. of serum ascorbic acid than healthy persons, and why in some patients the quantity of serum ascorbic acid cannot be materially raised by an increased addn. of vitamin C. The results of these examns. show that the difference generally is due neither to a defective absorption nor to an abnormal renal excretion, but must be due to another endogenous cause; in a few patients only there is a lack of absorption. V. Aschehoug

The effect of the thyrotropic and growth hormones of the anterior pituitary on the growth of the transplanted rat sarcoma. H. Morikawa. *Folia Endocrinol. Japon.* 15, 23–4(1939)(in German).—The thyrotropic and growth hormones were prepd. by alc. and Me_2CO pptn. from fresh bovine pituitary glands. The exptl. procedure was similar to that described in the earlier papers (*C. A.* 33, 9417[5,6]). The hormones were injected daily for 17 days into male white rats weighing 70–80 g. beginning immediately after transplantation of the sarcoma. The growth of the sarcoma decreased slightly after thymectomy or injection of the thyrotropic hormone. The growth hormone produced a rather distinct increase in sarcoma growth both in thymectomized and nonthymectomized rats, the effect being slightly greater in the latter. R. Berggren

The effect of the thymus and sex glands on the metabolism (tissue respiration and glucolysis) of the rat sarcoma. H. Morikawa. *Folia Endocrinol. Japon.* 15, 24–5(1939)(in German); cf. *C. A.* 33, 9417[5,6].—The sarcoma (Fujinawa strain) was removed between the 9th and 13th day after transplantation into male white rats weighing 70–80 g. and its respiration and glucolysis were estd. by the Warburg method. The respiration of the sarcoma was not appreciably influenced by thymectomy, orchidectomy or prolonged injection of thymoglandol (thymus ext.); it was increased slightly after feeding thymus powder or after prolonged injection of androstin (testicular hormone). The aerobic and anaerobic glucolysis was decreased after feeding thymus powder or after prolonged injection of thymoglandol and increased after thymectomy or prolonged injection of androstin. On direct addn. of thymoglandol to the extirpated sarcoma tissue *in vitro* the respiration increased regardless of the concn. of the added thymus ext.; the glucolysis was accelerated by a low concn. of thymus ext. and slightly inhibited by a high concn. The respiration also increased after direct addn. of androstin but the glucolysis did not change. Ruth Berggren

The significance of the cholesterol partition of the blood serum in surgery of the gall bladder. Otto C. Pickhardt, A. Bernhard and Irving L. Kohn. *Ann. Surg.* 110, 701–22(1939).—The detn. of the cholesterol partition of the blood serum, particularly the changes in percentage of free cholesterol, has been used as a measure of the functional reserve of the liver. A patient who exhibits a low functional reserve is a poor operative risk. The cholesterol partition has prognostic value in surgery of the gall bladder and biliary tract. R. Brown

The blood picture in hog cholera. H. C. H. Kernkamp. *J. Am. Vet. Med. Assoc.* 95, 525–9(1939).—The blood picture in hog cholera is characteristic of a severe leucopenia. No significant change in the nos. of erythrocytes or in the amts. of hemoglobin per unit vol. of blood occurs. Rachel Brown

Possible carcinogenic effect of anthracene and chrysene and some of their compounds. I. The effect of painting on the skin of mice. Joseph A. Polhia. *J. Ind. Hyg. Toxicol.* 21, 219–20(1939).—Chrysene, anthracene, oil-sol. chrysene red, water-sol. chrysene blue and water-sol. anthracene green when painted on mice failed to produce any characteristic cancerous changes on the skin. A. L. Elder

Prophylaxis of benzopyrene cancer; action of heavy doses of vitamin B_1, nicotinic acid or a phosphorylating enzyme system. J. Maisin, Y. Pourbaix and J. Camerman. *Compt. rend. soc. biol.* 132, 87–90(1939); cf. *C. A.* 33, 5482[6].—Skin cancer was produced in mice by application of benzopyrene soln. to the skin. Heavy doses of either vitamin B_1 or nicotinic acid, given with Na pyrophosphate, had some inhibiting action, as also did a yeast prepn. rich in active phosphorylating enzyme and the necessary accessory substances. L. E. Gilson

Standardization of the antiviral content of immune globulin from placental extract. Geoffrey Rake. *Proc. Soc. Exptl. Biol. Med.* 42, 9–11(1939).—Preliminary report. L. E. Gilson

Photoöxidation of blood plasma and tissues in buckwheat disease. Hans Smetana. *Proc. Soc. Exptl. Biol. Med.* 42, 60–4(1939).—There was no abnormal increase of O consumption during irradiation, by infrared, visible and ultraviolet light, of plasma and tissues of various organs of guinea pigs sensitized to light by prolonged feeding of buckwheat. No evidence was found that the susceptibility to light in buckwheat disease is due to a photodynamic substance. L. E. Gilson

Protective value of immune rabbit serum and its globulin fraction against experimental murine infection with Hemophilus pertussis. Henry W. Scherp, Wm. L. Bradford and Mary Wold. *Proc. Soc. Exptl. Biol. Med.* 42, 172–6(1939).—Immune rabbit serum protected mice against exptl. intranasal infection with *H. pertussis*. By pptn. in half-satd. Na_2SO_4 at 37° a globulin fraction was prepd. which had essentially the same protective capacity and agglutinating titer as the original serum but only 1/3 the protein content. L. E. Gilson

Listerella monocytogenes in relation to the Wassermann and flocculation reactions in normal rabbits. John A. Kolmer. *Proc. Soc. Exptl. Biol. Med.* 42, 183–6(1939).—Immunization of rabbits with living and heat-killed avirulent strains (4428 and F302) of *Listerella monocytogenes* did not produce complement fixing or flocculating reagins for antigens commonly employed in the serum diagnosis of syphilis. Neither strain produced sheep corpuscle agglutinin. Both produced complement-fixation antibodies and agglutinins for antigens of homologous strains of *Listerella*. L. E. Gilson

Bilirubin resorption in obstructive jaundice. B. G. P. Shafiroff, H. Doubilet and W. Ruggiero. *Proc. Soc. Exptl. Biol. Med.* 42, 203–5(1939).—Preliminary. L. E. Gilson

Preferential mottling of the enamel of rat molars [by fluoride]. Sara F. Dixon and Gerald J. Cox. *Proc. Soc. Exptl. Biol. Med.* 42, 236–7(1939).—Preliminary. L. E. Gilson

Tachyphylaxis to renin. E. G. McEwen, S. P. Harrison and A. C. Ivy. *Proc. Soc. Exptl. Biol. Med.* 42, 254–7(1939).—A method is given for obtaining a reliable, relatively stable, active renin prepn. from hog kidney. The production of the tachyphylaxis tolerance phenomenon by repeated injections at intervals of less than 2 hrs. in dogs is described. L. E. Gilson

Relation between latent period and growth rate in chemically induced tumors. Austin M. Brues, Albert E. Weiner and Howard B. Anderson. *Proc. Soc. Exptl. Biol. Med.* 42, 374–7(1939).—A high degree of correlation was found between the malignancy of chemically induced tumors, as measured by growth rate and mitotic

index, and shortness of the latent period before appearance of palpable tumors. This was true in the various responses of different strains of mice to the same agent, and in responses to different agents and modes of administration. Possibly the growth rate of a tumor in the microscopic stage is the main factor detg. the latent period.
L. E. Gilson

Calcium and phosphorus excretion in the urine of patients with renal or ureteral calculi. R. H. Flocks. *J. Am. Med. Assoc.* **113**, 1466–71(1939).—The Ca and P urinary excretion of 35 patients with renal calculi was studied. In 23 patients high urinary Ca was found. All patients with rapidly growing stones had high urinary Ca excretion. Patients with high urinary Ca responded to an acid ash diet with an excessively increased Ca output as compared with patients with low urinary Ca. A modified vitamin D intake increased the Ca output. A slight pathol. change in the kidney was assocd. with increased Ca; marked pathol. change was usually assocd. with lowered urinary Ca. Increased fluid intake merely dild. the Ca concn. of the urine. F. P. Griffiths

The enzyme problem and cancer. A. v. Christiani. *Z. Krebsforsch.* **49**, 221–30(1939). —Normal serum contains a substance with lytic action on carcinoma cells, which seems to be anchored in the albumin fraction. The enzyme nature of this substance is indicated by its thermolability, its insoly. in ether and the marked dependence of its activity on the H-ion concn. Carcinoma serum, with the exception of skin cancer, has no similar lytic effect on carcinoma cells. The substance present in the carcinomatous organism which protects the carcinoma cells from the lytic enzyme is a definite chemical substance, cholesterol butyrate. This substance is found in the carcinomatous organism in the serum and in the organs affected with carcinoma but not in normal serum or organs. The normal organism contains a dehydrase which changes the butyric acid normally formed and prevents the formation of cholesterol butyrate. Cholesterol butyrate has a marked affinity for cancer cells, is readily absorbed and probably takes part in the building up of the tumor. The substance in the normal organism that inactivates cholesterol butyrate in case it is formed in cell metabolism is a definite oxidation product of ergosterol. This combination acts as an inactivator and is present in very minute amt. The formation of this compd., very important physiologically, is due to the presence and activity of oxidases. It is probable that here too as with the carcinolytic agent there is present a coenzyme anchored in the organism to some protein as carrier. In the carcinomatous organism these oxidases are absent and so the ergosterol does not undergo oxidation and form an inactivator. After Ra or x-ray irradiation, which bring about direct oxidation, the inactivator is produced in the carcinomatous organism. E. Maier. *Ibid.* 231–5.—Two carcinomatous cases are cited which confirm the work of v. Christiani that before treatment no inactivators were present, and after Ra irradiation or electrocoagulation inactivators could be demonstrated. In expts. *in vitro* cancer cells of different origin showed different amts. of inactivators after Ra irradiation. Cancer cells that undergo spontaneous autolysis *in vitro* autolyze even more rapidly after Ra irradiation and inactivator is found after the irradiation. In this group are skin cancers and metastases from various cancers and these are sensitive to Ra. Other cancer cells do not readily undergo spontaneous autolysis *in vitro*, are not destroyed by Ra irradiation and do not form inactivator. In this group are cancers of the alimentary tract and forms of squamous cell carcinoma refractory to irradiation. Two cases are cited of clinical improvement after injection of inactivator and the application of dressings satd. with inactivator soln., in one case combined with Ra irradiation. In a no. of cases of carcinoma of the skin oxidases were absent before treatment and present after Ra irradiation. In this form of cancer there seems to be disturbance in the oxidase system while other enzymes, such as the dehydrases, are intact. As irradiation produces a destruction of leucocytes it is possible that the oxidases are set free from the destruction of the leucocytes. Further work, both chem. and clinical, should in the not far distant future yield new insight in cancer metabolism and indicate in what way irradiation therapy may lead to even greater success than at present. H. F. Holmes

The mineral content of the lungs of normal sheep as compared with that of the lungs in "lunger" disease. H. Marsh and D. P. Wilson. *Cornell Vet.* **29**, 345–51 (1939).—As compared with lungs of healthy sheep, those of diseased animals showed increased quantities of Si, Fe, Al, Ca, Mg and P, ranging from 17 to 90%, but there seemed to be no justification for assuming that this difference indicated any causal relation between these elements and the pathol. condition. K. D. Jacob

The role of concentration of ketone bodies in the processes of ketogenesis and antiketogenesis. The action of ketogenic substances. S. M. Leites. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 327–9(1939)(in English).—Hypodermal injections of a neutralized alk. ext. of acetone-treated pituitary powder, of adrenaline, of the "lipocaic substance" (Dragstedt) of the pancreas, or of the ultrafiltrate of an aq. ext. of acetone-treated liver powder generally gives rise to hyperketonemia only when the initial level of ketone bodies is below a "threshold value" (I) (7–10 mg. % in human subjects and dogs, calcd. as acetoacetic acid, and 7–10 mg. % in rabbits, calcd. as Me_2CO). When the initial value exceeds I a weak ketogenic effect, or, as in the majority of cases, hypoketonemia, occurs. Depletion of liver glycogen raises I. A 2nd injection of the ketogenic substance at the height of hyperketonemia produced by the 1st injection often results in hypoketonemia, while if injection at a high initial ketone body level is followed by hypoketonemia, a 2nd injection produces a profound hyperketonemic effect.
S. A. Karjala

The relation between proteolysis and protein synthesis in normal and Jensen's sarcoma tissue. B. I. Shomin. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 330–1(1939)(in German).—Protein synthesis in tissue slices, pastes or exts. of liver tissue was followed by the increase in substances precipitable by CCl_3COOH or sulfosalicylic acid or by the increase in residual N and free NH_2 groups. In all cases the synthetic and proteolytic processes alternated periodically. Protein synthesis by Jensen's sarcoma tissue was twice that of normal liver tissue. An ext. of the sarcoma tissue stored 25 days in the cold lost all its synthetic properties but retained the capacity to split protein substrates. The same alternation in synthesis and proteolysis was observed in autolyzates of rat, rabbit and chicken muscles. S. A. Karjala

Proteolytic autolysis of normal and malignant tumor tissue. A. S. Konikova. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 332–4(1939)(in German).—The proteolytic autolysis of mixts. of rat and rabbit muscle tissues is higher than that of each taken separately. Sarcoma tissue alone gives a high value, indicating that it is fundamentally different from normal tissue. Mixts. of tissues of heterogeneous tumors show no increase in proteolytic autolysis.
S. A. Karjala

Blood phosphatase changes in certain diseases. G. M. Vasil'ev. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 349–52 (1939)(in English).—A description of the detn. of blood phosphatase (I) by the Na_2PO_3OPh method of King (*C. A* **28**, 7285[1]). A distinct increase in I was observed in hepatic diseases. A proportional relationship between bilirubin and I in cases of increased I in cholecystitis was not always observed, although it was generally found in parenchymc cholecystitis and hepatic cirrhosis. No appreciable change in I was found in diabetes mellitus.
S. A. Karjala

The sulfur content of the hair of malignant tumor patients. K. S. Kosyakov. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 407–10(1939)(in English).—The normal S content of the hair of women 15–44 yrs. of age is 2.59% while that of men is 2.84%. In the age group 45–55 the values are 2.86 and 2.93%, resp. In the case of cancer in women no change is observed in the S content of the hair, while sarcoma causes an increase in S. In men

cancer causes a decrease in S which is greatest for cancer of the digestive tract, while sarcoma causes no change. S. A. Karjala

The cause of sterility in experimental athreosis. M. G. Sachs. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 521–3 (1939) (in English).—The basal metabolism of thyroidectomized rabbits falls to 1.56 cal. per kg./hr. compared to the normal 2.47 cal. per kg./hr. within 1 month after operation. An av. increase in wt. of 470 g. was observed. Ovulation, fertilization and development of the ovum are normal, but the advanced embryo dies. The injection of thyreoidin caused a slight increase in wt. with little change in the basal metabolic level. However, 2 parenteral injections of 1 mg. each of pure thyroxine (I) resulted in a rapid rise in the basal metabolic rate to 3.32 cal per kg./hr. and an av. loss in wt. of 320 g. Another injection of I after mating led to normal pregnancy and normal birth. Addnl. injections of I on the 13 18th day of pregnancy had no effect, indicating that I was no longer necessary after the thyroid gland of the embryo began to function. S. A. Karjala 2 3

The influence of an extract of the anterior pituitary on the development of experimental pancreatic diabetes. V. G. Baranov. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 32–4 (1939) (in English).—The administration of an ext. of the anterior pituitary to dogs 2.5–12 months after partial removal of the pancreas led to glucosuria which disappeared when administration of the ext. was stopped. Repeated administration led to a stable glucosuria and pancreatic diabetes. S. A. Karjala 4

Factors influencing carcinogenesis with methylcholanthrene. II. Lack of effect of foster nursing. Michael B. Shimkin and Howard B. Andervont. *U. S. Pub. Health Repts.* **54**, 2080–5 (1939); cf. *C. A.* **33**, 8287[4].—Foster nursing of male mice of a strain (C_3H) highly susceptible to the induction of subcutaneous sarcoma with 0.5 mg. methylcholanthrene in lard by mice of lower susceptibility to the agent (I and Y strains), or the foster nursing of male mice of strains more resistant to the action of methylcholanthrene on 1.0-mg. doses (Y strain) by mice of a highly susceptible strain (C_3H), does not alter the susceptibilities of the animals to formation of tumors with the hydrocarbon. Twelve references. J. A. Kennedy 5

Human serum as a stabilizer of scarlet fever streptococcus toxin diluted for the Dick test. Milton V. Veldee. *U. S. Pub. Health Repts.* **54**, 2131–7 (1939). The presence of 1 500 human serum, when added to the 10% phosphate buffer in normal saline commonly used in the country for the prepn. of the Dick toxin, effectively protects the skin-reacting factor against deterioration for an interval of time considerably over the present allowable dating period, within a temp. of 5–37°, and a pH level of 6.6–7.4. There is no evidence that the presence of so small a quantity of human serum significantly influences the resulting skin reaction in the human or the rabbit. J. A. Kennedy 6

Polarographic cancer diagnosis. Ernst Waldschmidt-Leitz and Karl Mayer. *Z. physiol. Chem.* **261**, 1–19 (1939).—Tabulated clinical data on cancer diagnosis by means of the polarograph on serum after a variety of treatments leads to the following method as most specific. The serum (0.5 cc.) is dild. with 1 cc. of H_2O, kept at 100° for 10 min., deproteinized by addn. of 1.5 cc. of 25% sulfosalicylic acid, filtered through hardened paper and 0.5 cc. of the filtrate mixed with 5 cc. of a soln. contg. 0.02675 g. $Co(NH_3)_6Cl_3$, 10 cc. of *N* NH_4Cl and 20 cc. of *N* NH_3 per 100 cc. The increase of the polarographic wave above normal is the diagnostic sign. Fevers are often accompanied by false positives. M. Levy 7 8

Chemistry of tumors. II. Isolation of glutamic acid from tumor proteins. Fritz Kögl, Hanni Erxleben and A. M. Akkerman. *Z. physiol. Chem.* **261**, 141–53 (1939); cf. *C. A.* **33**, 5060[6].—Racemic glutamic acid-HCl is twice as sol. as is *l*-glutamic acid-HCl. A ternary diagram of the system *d*-glutamic acid, *l*-glutamic acid and 20% HCl at 0° shows that no racemate exists. The failure of Chibnall (*C. A.* **33**, 7376[2]) to confirm the authors' previous work is due to the high losses on recrystn. of glutamic acid-HCl and to the preliminary isolation as the Ca salt from 90% alc. *dl*-Ca glutamate is at least 10 times as sol. as Ca-*l*-glutamate. Artificial mixt. of *l*- and *dl*-glutamic acid subjected to Chibnall's procedure result in pure *l*-glutamic acid. Calf embryos yield *l*-glutamic acid by Kögl's method and on adding *dl*-glutamic acid and applying Chibnall's method only *l*-glutamic acid was isolated. Kögl's method gave 59% of the added *d*-component. The exact process used by Kögl is described as follows. The aq. residue of the hydrolyzate after butanol and propanol extn. is concd. to 1 ml. per g. original protein, satd. with HCl at 0° and set aside for some days, sometimes after seeding with *l*-glutamic acid and with *dl*-glutamic acid. The ppt. after 3–4 days is filtered and washed on sintered glass filters with HCl satd. H_2O at 0°. The filtrate is brought to $^2/_3$ of the original vol. *in vacuo* and again satd. with HCl at 0° and set aside. After crystn. and filtration, a third crop may sometimes be obtained. The raw crystals are united, dried *in vacuo* over MeOH and recrystd. from 20% HCl, sometimes using C to remove color. Recrystn. losses should not exceed 10%. Partially racemized glutamic acid prepns. from tumors were treated with yeast and pure *d*-glutamic acid was isolated. The same was done by mech. sepn. of large crystals obtained by seeding supersatd. solns. of the racemic mixt. **III. Stereo chemistry of myoma and other tumors.** Fritz Kögl and Hanni Erxleben. *Ibid.* 154–71.—The amino acids isolated from 2 uterus myomas were racemized in part. One gave no glutamic acid, in the other the *l*-glutamic acid was found. From 4 to 10% racemization of leucine, hydroxyglutamic acid and hydroxyproline was found. An osteosarcoma gave amino acids with the following amts. of the *d*- form: arginine 3.8, glutamic acid 39, leucine 4.5, lysine 4.8, hydroxyproline 5.4 and valine 3.3%. Similar results are reported for a rabbit myoxoma (Sanarelli virus), a secondary carcinoma of the spleen and a carcinoma of the lung. The relation of extent of racemization and malignancy is not confirmed. There is probably a relationship between kind of tumor and racemization. Milton Levy 9

Biologic test for hyperpituitarism by determination of the dilatation of the melanophores produced in the hypophysectomized frog. G. Jeannenev, L. Servantie, G. Hirtz and J. Bentejac. *Bull. acad. méd.* **121**, 762–8 (1939).—The test of Collin and Drouet (cf. *C. A.* **29**, 4448[9]) is modified in that the urine sample is injected into the hypophysectomized frog and the effect on the melanophores is measured after 1 hr. The test is rendered quant. by comparison with a standard of pituitary powder. Only frogs are used which give a min. reaction with $^1/_{50}$ to $^1/_{100}$ of an international unit. A. E. Mayer

Blood glutathione in pulmonary tuberculosis. Oscar P. Aguilar and Ignacio J. del Villar. *Semana méd.* (Buenos Aires) **1939**, **II**, 1018–27.—The blood glutathione is increased in 80% of cases of pulmonary tuberculosis with a tendency of reversal of the ratio oxidized:reduced glutathione. High values are found especially in grave cases, in patients with artificial pneumothorax and mostly in coincidence with increase of sedimentation of the erythrocytes. A. E. Meyer

Clinical and experimental investigations on creatine metabolism. Erling Wang. *Acta Med. Scand.*, Suppl. **105**, 338 pp. (1939).—A review of the entire subject of creatinuria. The exptl. work was done on urine, blood and muscles both in patients and in animals. On the usual hospital food it was found that the av. daily creatine excretion for men was 18 mg. and for women 48 mg., though the max. amts. were about 4 to 5 times as large. The creatine excretion in thyreotoxicosis was independent of the basal metabolism but seemed to be related to thyroxine itself. During treatment with I_2 the creatinuria decreases about parallel to the general improvement. At the same time the creatinine excretion diminishes somewhat in direct ratio to the severity of thyreotoxicosis and during I_2 treatment it remains unaltered. Creatinuria is frequently assocd. with fevers but does not seem to depend so much upon the severity of the febrile condi-

tion as upon the extent to which the patient is affected. The creatinine elimination in fever is also below normal. So far as pathol. states such as uremia, hypertension, cardiac insufficiency, etc., are concerned, the creatine and creatinine excretion apparently are unaffected, creatinuria being frequently present only when patients are in a bad general condition. Phlebitis profonda is assocd. with extensive creatinuria, which increases and decreases parallel to the clinical symptoms. The creatinine elimination in these cases is again low. In poliomyelitis creatinuria is present which is proportional to the extent and severity of the disease. During improvement of patients the creatinuria recedes practically in a parallel manner. Here the creatinuria is believed to serve as a measure of the severity of the disease. Generally, in the early stages of the disease, the creatinine excretion decreases. In patients with fractures or with sciatica, but not with arthritis assocd. with muscle atrophy, there is an increased elimination of creatine but the excretion of creatinine is not affected in any significant way. In cases of creatinuria there is generally an elevation of the serum creatine content. Expts. on rabbits show that in exptl. thyrotoxicosis produced by thyroxine injections the creatine content of muscles, and especially the phosphocreatine, is much lowered. Intravenous injection of creatine does not alter the creatine and phosphocreatine content of their muscles, and when this is injected in combination with thyroxine the effect is no different than in rabbits treated with thyroxine alone. Thyroidectomized rabbits manifest a somewhat higher muscle creatine and phosphocreatine content than control animals. It is, therefore, concluded that creatinuria is due to loss of creatine from the muscles. Creatinuria is an entirely unspecific condition but is of clinical importance as an index of the condition of the muscles affected in various diseases. S. Morgulis

Transient calcinosis, accompanying ulcerative colitis. Håkon Rasmussen. *Acta Med. Scand.* **101**, 491–5 (1939).—A case of colitis is described with multiple subcutaneous calcinosis which disappeared with the cure of the ulcerative colitis condition. The relation of this to the excretion of Ca and P is discussed. S. Morgulis

Transplantation of the hypophysis in a diabetes insipidus patient. Eskil Kylin. *Acta Med. Scand.* **101**, 566–7(1939).—A hypophysis transplantation by K.'s method was made into a young man suffering from diabetes insipidus. On the day after the operation the diuresis decreased from about 5 l. per day to a vol. less than a l. and the sp. gr. increased from 1.00 to 1.020. The improvement was found to persist about 2 months later when the article was published. S. Morgulis

Sucrosuria. A rare metabolic error. A. W. Elmer, M. Kasowska and L. Ptaszek. *Acta Med. Scand.* **101**, 596–608(1939).—Sucrosuria may be regarded a rare metabolic freak. So far only 5 instances have been described. There are 2 types of this metabolic error: (1) the sucrosuria of exogenous origin, even when very small amts. are ingested, which is attributed to the probable loss of the sucrose enzyme in the alimentary tract, the absorbed sucrose being eliminated in the urine unchanged; (2) an endogenous sucrosuria, entirely independent of any sucrose intake, which is perhaps assocd. with an alteration in pancreatic or hepatic function. S. Morgulis

Etiology of gallstones. A critical survey of the literature and a study of the applicability of the various theories in two hundred and thirty-nine operative cases. E. Franklin Carter, Carl H. Greene, J. Russell Twiss and Richard Hotz. *Arch. Surg.* **39**, 691–710(1939).—The compn. of hepatic bile or of bile obtained by duodenal drainage is not related to changes in the chem. compn. of the blood, nor is the cholesterol content of the bile related to that of the blood. 84 references. John T. Myers

Some problems concerning the pathogenesis of allergic eczemas elucidated by experiments on sensitization with dinitrochlorobenzene. H. Haxthausen. *Acta Dermato-Venereol.* 20, 257–72(1939).—The skin of normal persons was sensitized to dinitrochlorobenzene (I) by painting an area of the epigastrium with a 30% soln. Intensive ultraviolet light irradiation did not prevent the sensitization when this area was painted the next day. Moderate freezing with CO_2 snow immediately after the painting to 8 days later prevented desensitization in 80% of the cases. The expts. indicated that the epidermal cells play a decisive role in sensitization, probably by producing an antibody when they are exposed to I, and that this antibody possesses a highly developed specificity. Maurice M. Rath

The Lange test. I. The influence of particle size and hydrogen-ion concentration of gold sols upon Lange test readings on paretic spinal fluids. P. K. Glasoe and C. H. Sorum. *J. Lab. Clin. Med.* **25**, 1–7(1939).—The sensitivity of the test for paresis increases with an increase in the particle size of the Au sol. and decreases with an increase in pH. Large particles are less stable, sizes above 40 mμ give sols that are too murky to be suitable. The results indicate that the optimum combination is a sol of small particle size with a relatively low pH (about 6). Howard W. Robinson

Is there a platelet-reducing substance in the spleen of thrombocytopenic purpura? Ralph H. Major and C. J. Weber. *J. Lab. Clin. Med.* **25**, 10–13(1939).—Intravenous injections of the exts. of the spleens from 2 patients into rabbits failed to confirm the findings of Troland and Lee (*C. A.* **32**, 3018[1]; *J. Am. Med. Assoc.* **111**, 221 (1938)). Variations in the platelet counts of the rabbits were no greater than what might occur during the injection of a variety of materials. Howard W. Robinson

Local allergic changes in rabbit sarcoma tissue Nitizen Inand Gentetu Ryo. *J. Chosen Med. Assoc.* **29**, 1645–56(English abstr. 107–8)(1939).—A morphological study, showing that injections of horse serum before and after inoculation of rabbits with sarcoma emulsion produce inflammatory processes of sarcoma tissues which are caused by the anaphylactic toxin, resulting in a partial disappearance of tumor cells, and proliferation of connective tissue. S. Tashiro

Anemia, and deterioration of ferrous sulfate and ascorbic acid solutions. H. W. Tomski and L. J. Waller. *Pharm. J.* **142**, 239–41(1939).—Biochem. methods, hematological tests, gastric analysis and urine tests (ascorbic acid (*A*) excretion) are important in the modern study of anemia, which is discussed. The stability of *A* in aq. solns. of various concns. was detd; stability of excreted *A* in normal urine was attained in 2–4 hrs. after a loss of, resp., 6.7 and 15.4% (cf. *C. A.* **32**, 5042[1]). The therapeutic value of Fe^{++} vs. Fe^{+++} prepns. in anemia is reviewed (cf. *C. A.* **26**, 4880, 5664). Addn. of *d*-glucose to $FeSO_4$ soln. tends to stabilize it. A "stable" $FeCl_2$ prepn. (Brit. Pharm. Addendum, 1936) developed fungus growth within a week. With a similar mixt. of 2.5% $FeSO_4$, 0.2% citric acid and 2% dil. H_2SO_4, no such growth will form. A flavored mixt. based on this compn., and including *d*-glucose, kept for 6 months. S. W.

Blood clearance of free chloral in normal and liver-damaged dogs. B. Mukerji and R. Ghose. *Nature* **144**, 636(1939); cf. *C. A.* **33**, 7335[6].—In recently induced and chronic liver damage, a significant increase in free chloral concn. occurs in the blood within an hr. after the oral administration of chloral hydrate to dogs. Blood clearance of free chloral may, therefore, be used as a test for detoxicating efficiency of the liver. E. D. Walter

Inhibition of transplantable mouse tumor growth by tissue extracts and their protein fractions. D. A. MacFadyen, Ernest Sturm and James B. Murphy. *J. Exptl. Med.* **70**, 475–83(1939).—Mammary tissue of pregnant rabbits contains an agent which inhibits the growth of Bashford adenocarcinoma 63 in mice but this material is without effect on the Crocker sarcoma 180. Of the tissues so far studied the mammary gland of rabbits yielded the most active product. The factor is found, with diminished activity, only in the protein fraction obtained from the aq. ext. by full satn. with $(NH_4)_2SO_4$. C. J. West

Production and preservation of specific antiserums for blood-group factors A, B, M and N. Wm. C. Boyd. *J. Immunol.* **37**, 65–75(1939).—Methods are given for

the production of the specific antiserums. For the preservation and identification of the serums 1% solns. of neutral acriflavine (0.015 cc. to 1.0 cc. serum) or brilliant green (0.02 cc. to 1.0 cc. serum) were used. In several instances such serums have been preserved in usable condition for more than 5 years. Charles A. Zittle

A note on the calculation of antibody-antigen ratio. Alfred E. How. *J. Immunol.* **37**, 77–83(1939).—A theoretical calcn. of the antibody-antigen ratio involving the mol. wt. of the antigen and antibody is given which furnishes a simpler equation than previously obtained (Boyd and Hooker, *C. A.* **28**, 3788[8]). There is included a correction factor obtained from the comparison of actual systems of spheres with these theoretical calcns. Charles A. Zittle

The specific protein in rabbit antipneumococcal serum and its relation to the increase of serum protein during immunization. M. Bjørneboe. *J. Immunol.* **37**, 201–6(1939).—The specific protein and total protein content of rabbit antipneumococcal serums were detd. For the specific protein the method of Heidelberger and Kabat (*C. A.* **29**, 1127[6]) for agglutinin N was used. The nonprotein N, detd. after pptn. of the protein with 5% trichloroacetic acid (2 cc. serum + 5 cc. 5% acid), of normal serums and immune serums was very nearly the same (mean 0.30 and 0.27 mg. per cc., resp.) indicating the increase in total N during immunization and the increase in protein N are identical. Fifty-six serums of different types were analyzed for total N (10.3–13.5 mg. per cc.) and specific N (0.08–3.29 mg. per cc.); a difference in the 2 values of 10.2 ± 0.45 (S. D.) mg. per cc. was found. Analysis of 11 normal serums gave a mean of 10.3 ± 0.73 (S. D.) mg. per cc. The conclusion is drawn that the specific N is equal to the total N of the antiserum in question minus total N of normal sera or that the antibody-protein is identical with the increase in serum protein during immunization. All serums studied were pools from at least 5 rabbits; it is stressed that the above relation is only applicable for such serums. C. A. Zittle

Behavior of acid-treated antipneumococcal rabbit antibodies. A. J. Weil, A. M. Moos and Frances L. Clapp. *J. Immunol.* **37**, 413–24(1939).—Solns. of pneumococcal rabbit antibody of various types (types 1, 2, 3, 5, 7, 8, and 14) were acidified to various pH (4.4 to 2.7) with lactic, hydrochloric or sulfuric acids. The nature of the acid was found to be of no importance. The ppts. obtained were removed and were always found to contain no antibody. The acidified antibody solns. were neutralized, and dialyzed against 0.85% NaCl for 48 hrs. Antibody solns. treated as described showed an increase in the N precipitable by specific polysaccharide (up to 50%), and a shift in the antigen-antibody combining ratio occurred at the same time; the ratio of mouse-protective value/N specifically pptd. was lowered. The complement-fixing quality was impaired or lost when this last ratio was lowered. Loss of complement-fixing quality was also observed with antibody refined by partial peptic digestion; these serums also had low mouse-protective values. The properties of causing capsular swelling and of eliciting passive anaphylactic shock were unimpaired in acid-treated serums. The implications of the observations are discussed. The use of substituted naphthalenesulfonic acids for purification of pneumococcal antibodies is described. Such purified antibody solns. responded similarly to acid treatment. Charles A. Zittle

Serological differences of the group character A in different parts of the human organism. V. Friedenreich, G. Thyssen and G Hartmann. *J. Immunol.* **37**, 435–43 (1939).—Serological tests, with isoagglutinin anti-A and rabbit immune anti-A serums, of human A blood corpuscles and of human A saliva show that the A antigens of these 2 sources are not identical. Aq. exts. of submaxillary glands of group A reacted like the saliva; exts. of other glands, and gastric juice and semen reacted like the corpuscles. The A substance of ox saliva reacted like the A substance of human corpuscles. C. A. Zittle

Role of "auto-antigens" in the pathogenesis of physical allergy. S. Karády. *J. Immunol.* **37**, 457–61(1939).—Expts. are presented which seem to indicate a new mechanism in the production of phys. allergies by which the organisms own protein can be changed by various phys. agents, such as heat and cold, so that it requires antigenic properties and becomes an "auto-antigen." Charles A. Zittle

Studies on meningococcal infection. XI. A quantitative study of the precipitative reaction between type I polysaccharide and antimeningococcal horse serums. Henry W. Scherp. *J. Immunol.* **37**, 469–87(1939).—The immunological properties of a polysaccharide prepd. from type I meningococci (*C. A.* **29**, 5145[1]) and of antimeningococcal horse serums were studied by means of quant. analysis of the precipitative reaction; equations and graphs are given relating the mg. of polysaccharide added and the mg. of antibody-N pptd. The results showed that the polysaccharide was a mixt. of precipitinogens. The data indicated that the polysaccharide contained not only a type-specific component but also a group specific one; that the univalent type I serum which was studied contained only type-specific antibody; and that the multivalent sera which were studied contained more group- than type I-specific antibody. C. A. Z.

H—PHARMACOLOGY

CARL F. SCHMIDT

Effects of continuous intravenous injection of dextrose in increasing amounts on the blood-sugar level, pancreatic islands and liver of guinea pigs. C. Arthur Woerner. *Anat. Record* **75**, 91–105(1939); cf. *C. A.* **32**, 5492[6].—The liver cells were filled with glycogen. The increase in blood-sugar level was very variable. There appeared to be some correlation between terminal blood-sugar level and the condition of the cells in the islands of Langerhans. There was also some correlation between the liver glycogen and fat and the condition of the island cells. Philip D. Adams

Sulfonamide treatment of experimental tuberculosis in guinea pigs. Konrad E. Birkhaug. *Beretninger Chr. Michelsens Inst.* 9, 3(1939).—Expts. on 48 guinea pigs were carried out, the guinea pigs being inoculated subcutaneously with approx. 600 viable bovine tubercle bacilli. Half of these animals received daily intramuscular injections of 0.44 cc., increasing gradually to 2.2 cc. per kg. of the 2.5% soln. of "prontosil sol." (10.9 to 54.4 mg. of the sulfonamide compd. per kg.) during 21 post-inoculation weeks. The development and degree of tuberculin allergy were significantly delayed during the first 4 weeks as a result of the sulfonamide treatment. Thereafter the tuberculin hypersensitiveness remained the same in the treated and untreated animals. The prolonged sulfonamide treatment caused no appreciable change in the leucocyte count nor any eosinophilia. All the numerical data were analyzed statistically. The inhibitory action exerted by the sulfonamide compd. "prontosil sol." on the progress of tuberculous changes is due to a bacteriostatic effect which renders the virulent tubercle bacillus temporarily impotent and thus allows the natural defence mechanism of the body to dispose of the disabled mycobacteria by phagocytosis. The huge dose of "prontosil sol." required to bring about this indirect effect on virulent tubercle bacilli (2.0 to 2.5 cc. per kg. of a 2.5% soln., or 100 to 125 cc. daily in a person weighing 50 kg.) makes it obvious that this form of sulfonamide falls short of the ultimate goal in the chemotherapy of clinical tuberculosis. V. Aschehoug

Sulfanilamide intoxication. Erik Vogt. *Nord. Med.* **4**, 3369–71(1939).—A review of the most important toxic symptoms of sulfanilamide and a report of a case of nonfatal sulfanilamide intoxication. V. Aschehoug

The effect of anterior pituitary on tissue respiration, especially the influence of various pharmaceutical agents on this effect. III. The influence of potassium iodide and diiodotyrosine. M. Aisawa. *Folia Endocrinol. Japon.* **15**, 25–6(1939)(in German); cf. *C. A.* **33**, 8791[6,7].—The O consumption (estd. by the Warburg method) of the liver, spleen, thyroid and kidney of male white rats

weighing about 150 g. was increased after injection of saline ext. of the anterior pituitary for 5 days. This increase was distinctly reduced by the simultaneous injection of KI or, to a smaller extent, by diiodotyrosine. IV. **The influence of insulin and of saline extract of the adrenal cortex.** *Ibid.* 26–7.—The adrenal cortex ext. was prepd. as follows: The adrenal cortex was carefully sepd. from the medulla and ground. Ten times its wt. of physiol. saline was added and the mixt. was allowed to stand, with occasional shaking, for 24 hrs. Any adrenaline present was destroyed by passing O through the ext. for 3 hrs. Male white rats, weighing about 150 g., received daily one injection of 0.2 cc. adrenal cortex ext. per 100 g. body wt. for 10 or 20 days or one injection of 0.005 cc. insulin (0.05 unit) per 100 g. body wt. for 10 days. Beginning on the 6th or 16th day of injection and continuing for 5 days a daily dose of 0.4 cc. saline ext. of the anterior pituitary was also injected into each rat. The increase in O consumption of the liver, spleen, thyroid and kidney observed after simple injection of the anterior pituitary ext. was distinctly lowered by the pretreatment with insulin or with the adrenal cortex ext., the effect of the latter being greater after injection for 20 days than after that for 10. V. **The influence of arsenious acid, sodium fluoride and borax.** *Ibid.* 39–40.—One daily dose of 0.03 mg. arsenious acid, 1.0 mg. NaF or 20 mg. borax, each per 100 g. body wt., was injected subcutaneously into male white rats for 10 days. Beginning on the 6th day of injection and continuing for 5 days a daily dose of 0.4 cc. 5% saline ext. of the anterior pituitary was also injected into each rat. The rest of the exptl. procedure was the same as in the previous papers. The increase in O consumption of the liver, spleen, thyroid and kidney observed after simple injection of the anterior pituitary ext. was lowered by the pretreatment with arsenious acid, NaF or borax. Ruth Berggren

Decurvon, a pectin-insulin, with a prolonged action. B. Brahn and T. Langner. *Nederland. Tijdschr. Geneeskunde* **83, III,** 4621–31(1939).—Protamine insulin or similar insulin prepns. have the disadvantage that the velocity of insulin mobilization varies. The authors prefer a prepn. which contains the insulin uncombined and which is free from protein, hence cannot give rise to allergic reactions such as sometimes occur after injection of protamine. Also the irritating zinc salt is absent. Pectin insulin is more slowly absorbed merely because of the increased viscosity of its soln., as is demonstrated by expts. on rabbits and men. In rabbits the blood-sugar level is reduced by 19% 4 hrs. after injection of 1 unit of pectin-insulin. R. Beutner

Hemostatic drugs as prophylactics in tonsilectomy and adenectomy. L. B. W. Jongkees. *Nederland. Tijdschr. Geneeskunde* **83, III,** 4640–8(1939).—One or two hrs. after ingestion of 3 to 5 g. of $CaCl_2$, as an unsweetened but flavored 10% soln. the clotting time of blood is markedly shortened; it is not necessary to administer $CaCl_2$ for several days. A pectin prepn. was found to be inefficient. The bleeding time is not influenced. R. Beutner

Consequences of narcosis or of asphyxia? Experimental data on the influence of nitrous oxide and of oxygen-lack on the central nervous system. H. R. van der Molen. *Nederland. Tijdschr. Geneeskunde* **83, IV,** 4921–9 (1939).—Inhalation of a N_2O + O_2 mixt. with less than 8% O_2 for several hrs. causes serious degeneration of the ganglion cells of the cerebrum. The same holds for a 100-hr.-narcosis with a mixt. contg. 20% O_2. R. Beutner

Lead-bismuth and bismuth lines in Indonesians and their histochemical identification. H. B. G. Broijer, G. O. E. Lignac and W. L. C. Veer. *Nederland. Tijdschr. Geneeskunde* **83, IV,** 5041–8(1939).—The lead line proved to contain lead and bismuth. By well-known chem. methods and by the reaction of Feigl lead and bismuth lines in the tissues can be differentiated. R. Beutner

Encephalopathy produced by manganese. Fr. Grewel and E. Sassen. *Nederland. Tijdschr. Geneeskunde* **83, IV,** 5464–71(1939).—Mn poisoning leads to simultaneous cerebral and liver disturbances. R. Beutner

Cardiometric study of the influence on cardiac contraction of the inhalation of carbon dioxide and of oxygen. Influence of oxygen therapy in the myocardiac intoxication from chloroform. L. Dautrebande and R. Charlier. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9,** 214–19(1939).—Tracheal inhalation of moderate doses of CO_2 or O_2 by the anesthetized dog causes a considerable increase in the frequency and amplitude of cardiac contractions; large doses of CO_2 cause a progressive decrease. O_2 inhalation decreases somewhat the toxic effect of $CHCl_3$ on the myocardium. E. Curzon

Early reaction of the hepatic parenchyma after inhalation of carbon tetrachloride. S. Zylberszac. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9,** 240–1(1939). E. Curzon

Effect of phenylisopropylamine (benzedrine) on the metabolism of the nonanesthetized dog. A. L. Delaunois and R. Marri. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9,** 242–3(1939).—Five fasting dogs were intramuscularly injected with 0.5–1.0 mg. benzedrine per kg. Ten min. after injection both O_2 consumption and CO_2 output had increased markedly and R. Q. had fallen an av. of 0.042. In about 45 min. the values were back to normal. E. Curzon

The physiological response to isopropyl ether and to a mixture of isopropyl ether and gasoline. W. Machle, E. W. Scott and Joseph Treon. *J. Ind. Hyg. Toxicol.* **21,** 72–96(1939).—Ingestion of 7–9 cc. of isopropyl ether per kg. body weight (rabbits) produces death. A concn. of 6.0% by vol. in air is rapidly fatal to monkeys, rabbits and guinea pigs; 3.0% produces incomplete anesthesia; 1% mild intoxication. Gasoline-isopropyl ether blends produced less intense but not significantly different effects. A. L. Elder

Toxic effects upon rabbits of pentachlorophenol and sodium pentachlorophenate. Robt. A. Kehoe, Wm. Deichmann-Gruebler and Karl V. Kitzmiller. *J. Ind. Hyg. Toxicol.* **21,** 160–72(1939).—Rabbits absorb lethal amts. of these through the skin. 0.22 mg. per kg. of body weight taken internally is fatal. Workmen handling lumber treated with pentachlorophenol should wear suitable protective clothing. A. L. Elder

The toxicology of some glycols and derivatives. E. P. Laug, H. O. Calvery, H. J. Morris and G. Woodward. *J. Ind. Hyg. Toxicol.* **21,** 173–201(1939).—The order of increasing toxicity is propylene glycol, diethylene glycol, ethylene glycol, diethylene glycol monoethyl ether, dioxan and ethylene glycol monoethyl ether. Studies were made on rats, mice and guinea pigs. Propylene glycol may be converted into a normal body constituent Bibliography. A. L. Elder

Fixation of toxic substances in the endocrine glands. René Fabre. *Bull. soc. chim. biol.* **21,** 959–64; *Bull. acad. méd.* **121,** 544–59(1939).—In dogs anesthetized with $CHCl_3$ the amts. of $CHCl_3$ fixed per g. of fresh tissue decreased in the order, adrenal cortex, adrenal medulla, thyroid, blood, pancreas and testicles. In an 18-kg. dog given 1 g. barbital daily for 10 days the amts. found in the tissues were, thyroid 11.2, adrenals 9.7, liver 8.5, brain 5.8, pancreas 4.8, blood 4.4 and testicles 2.4 mg. % of barbital. In dogs with chronic dichromate poisoning the Cr contents of the tissues were, hypophysis 2.5, liver 2, adrenals 0.4, thyroid 0.15 and testicles 0.072 mg. %. In rabbits ingesting NaF over long periods the values were, hypophysis 82.3, adrenals 1.56, liver 0.52, blood 0.95 and testicles 0.33 mg. % F. L. E. Gilson

Influence of absorption of glucose on the free sugars and glycogen of the liver. F. Rathery and P. M. de Traverse. *Bull. soc. chim. biol.* **21,** 978–1020(1939).—After ingestion or injection of glucose the liver glycogen of normal dogs often decreased while the free glucose increased. Changes in the muscle glycogen were also irregular. In phlorizinized dogs the slow intravenous injection of glucose lowered liver glycogen without affecting the free sugar level, while in depancreatized dogs the same treatment sometimes

increased liver glycogen and the free glucose of the liver tissue. L. E. Gilson

Influence of temperature on the contraction of guinea-pig intestine provoked by histamine. Rudolf Zadina. *Compt. rend. soc. biol.* **132**, 28–31(1939).—The contraction produced by 0.5 γ histamine per 100 cc. (in Locke soln.) is greater in amplitude at 31–32° than at lower or higher temps. Throughout the temp. range 21–38° the duration of the contraction decreases with increase in temp. according to a logarithmic curve. **Influence of the condition of the isolated intestine on contractions provoked by histamine.** *Ibid.* 31–2.—The most sensitive prepn. is the intestine from a young (200–250 g.) guinea pig which has fasted 5–6 hrs. Longer fasting decreases sensitivity. L. E. Gilson

Influence of sodium evipan narcosis on urinary secretion in the dog. Maurice Plumier. *Compt. rend. soc. biol.* **132**, 34–6(1939).—Urine vol. and the concn. of Cl and phosphate decrease to less than 1/8 the normal; urea concn. increases or does not change. L. E. Gilson

Transient experimental changes in the refractive power of the media of the eye. Roger Weekers. *Compt. rend. soc. biol.* **132**, 39–41(1939).—Feeding galactose to rats causes polydypsia, polyuria and an increase in the dioptric power of the eye which approaches myopia. The cryst. lens is especially affected. The symptoms disappear when the galactose is discontinued, except that prolonged treatment produces cataract. L. E. Gilson

Fate of indole in the dog. G. Barac. *Compt. rend. soc. biol.* **132**, 41–3(1939).—Intravenously injected indole is converted to indoxyl in the liver. L. E. Gilson

The pharmacological action of deuterium oxide. VIII. Action on the central nervous system. Julian B. Herrmann. *J. Pharmacol.* **67**, 265–75(1939); cf. *C. A.* **33**, 3884⁴.—Application of D_2O to the cerebral cortex produces a marked state of catalepsy in cats and monkeys. Injected D_2O disappears from the cerebrospinal fluid within 30 min. Encephalographic detns. parallel the objective findings of cerebral depression. Application of D_2O to the spinal centers of cats and frogs has no apparent effect on nerve impulse transmission. Application of D_2O to nerve or muscle of nerve-muscle has no obvious effect on nerve impulse transmission or muscle contraction. L. E. Gilson

The depressant action of picrotoxin and metrazole. James M. Dille and Lloyd W. Hazleton. *J. Pharmacol.* **67**, 276–89(1939).—Picrotoxin and metrazole may, in addn. to their stimulant action, produce depression in rats and rabbits. This depression is manifest in rabbits by loss of placement reactions which indicates that cortical function is impaired. It appears with doses of picrotoxin which approach but do not reach convulsive levels. With convulsive doses the depression appears before the convulsive attack and lasts for a considerable time afterward and is apparently independent of the convulsions. The depressive action of metrazole is less marked. L. E. Gilson

Blood concentration in morphine addicts. Edwin G. Williams. *J. Pharmacol.* **67**, 290–8(1939).—In man morphine addiction is assocd. with blood hydration. L. E. Gilson

Effect of liver damage on the blood level and action of paraldehyde. Harry Levine, A. J. Gilbert and M. Bodansky. *J. Pharmacol.* **67**, 299–306(1939).—The hypnotic effects and the blood paraldehyde curve obtained with a given dose of paraldehyde are definitely prolonged in dogs with liver damage produced by 90-min. deep $CHCl_3$ anesthesia 2 days previously. Similar blood levels of paraldehyde produced the same degree of narcosis in normal dogs and dogs with liver damage. L. E. Gilson

Protective effect of sulfapyridine, sodium sulfapyridine, and sulfanilamide in pneumococcus infection types I, II and III. G. W. Raiziss, M. Severac, J. C. Moetsch and L. W. Clemence. *Proc. Soc. Exptl. Biol. Med.* **42**, 12–17 (1939).—The compds. delayed but did not prevent death in infected mice. Sulfanilamide was the least effective. L. E. Gilson

Effect of carbon tetrachloride on the serum amylase of dogs. J. O. Hanson. *Proc. Soc. Exptl. Biol. Med.* **42**, 21–2(1939).—The normal values for serum amylase in dogs are much higher than those for human serum. Each dog has its own level of normal variation. Repeated doses of 2–10 cc. CCl_4, given orally every 2–3 days, caused a 50–70% decrease in serum amylase, with recovery of the normal level a week after treatment was discontinued. The CCl_4 did not affect blood-sugar levels. L. E. Gilson

Recovery of carbon monoxide-poisoned rats after x-ray treatment. John A. Cameron. *Proc. Soc. Exptl. Biol. Med.* **42**, 29–30(1939).—Immediate exposure to x-rays for 5–10 min. seemed to hasten the recovery of CO-poisoned rats in some cases. L. E. Gilson

Carotid body reflexes in the dog. C. F. Schmidt, J. H. Comroe, Jr., and R. D. Dripps, Jr. *Proc. Soc. Exptl. Biol. Med.* **42**, 31–2(1939).—Previous conclusions (cf. *C. A.* **32**, 1778⁵) are modified. Carotid chemoreceptors of vagotomized dogs anesthetized with morphine and chloralose are sometimes continuously active. L. E. Gilson

Heparin and plasma albumin in relation to thromboplastic action of trypsin, cephalin and brain extracts. John H. Ferguson. *Proc. Soc. Exptl. Biol. Med.* **42**, 33–7(1939); cf. *C. A.* **33**, 6993⁶, 8226⁸, 8258¹. Sufficient heparin can greatly delay plasma coagulation even under conditions most favorable for the action of trypsin, namely, abundance of cephalin and Ca. Clotting eventually occurs in all cases. Thrombin formed in the presence of heparin is fully potent. Fresh tissue exts. have a much greater thromboplastic potency than can be accounted for on the basis of their phospholipide content. Plasma albumin acts synergistically with heparin in delaying clotting. L. E. Gilson

Sugar tolerance of alcoholic patients. Karl M. Bowman, Joseph Wortis, Leo L. Orenstein and Walter Goldfarb. *Proc. Soc. Exptl. Biol. Med.* **42**, 37–40(1939); cf. *C. A.* **33**, 7385³. On admission there was a marked decrease in the sugar tolerance of a group of 18 alc. patients, probably because of undernutrition. After one week in the hospital on a normal diet the sugar tolerance was improved. L. E. Gilson

Effect of sulfanilamide and sulfapyridine on experimental infections with Listerella and Erysipelothrix in mice. J. R. Porter and Wm. M. Hale. *Proc. Soc. Exptl. Biol. Med.* **42**, 47–50(1939).—Either compd. saved about 80% of the mice infected with *Listerella monocytogenes* but neither had any protective action whatever in mice infected with *Erysipelothrix*. L. E. Gilson

Administration of heparin by mouth. Albert Fischer and Tage Astrup. *Proc. Soc. Exptl. Biol. Med.* **42**, 81–2(1939); cf. *C. A.* **33**, 6272³.—In mice heparin is not absorbed from the alimentary tract but is excreted unchanged in the feces in the course of about 2 days. L. E. Gilson

Gynecomastia associated with cirrhosis of the liver. Hugh A. Edmondson, Samuel J. Glass and Sydney N. Soll. *Proc. Soc. Exptl. Biol. Med.* **42**, 97–9(1939).—In several chronic alcoholics atropic cirrhosis of the liver was accompanied by ascites, testicular atrophy, gynecomastia and abnormally high urinary estrogen and androgen contents. It is suggested that the gynecomastia is the result of the liver becoming unable to inactivate sex hormones. L. E. Gilson

Calcium creosotate. V. Nature of phenols eliminated in urine. Edwin J. Fellows. *Proc. Soc. Exptl. Biol. Med.* **42**, 103–7(1939).—Large single doses or repeated therapeutic doses of Ca creosotate produced bacteriostatic urine in rabbits or in normal human subjects. Rabbits excreted practically all of the creosote in conjugated form. No conclusive evidence of removal of methoxy groups was found. Cf *C. A.* **31**, 6339¹. L. E. Gilson

Quantitative comparison of responses of isolated and of intact intestine to seven sympathomimetic amines. K. W. Aumann and W. B. Youmans. *Proc. Soc. Exptl. Biol. Med.* **42**, 111–12(1939); cf. *C. A.* **33**, 5517⁶.—On

dog and rabbit intestines the inhibiting actions of *l*-adrenaline, *dl*-arterenol and cobefrine were of about the same order of potency. The potency of *l*-neosynephrine, epinine and kephrine was 0.1–0.01 that of adrenaline, and the potency of *dl*-synephrine about 0.001 that of adrenaline. L. E. Gilson

Effect of cobalt on erythropoiesis in anemic rabbits. Wm. Kleinberg, Albert S. Gordon and Harry A. Charipper. *Proc. Soc. Exptl. Biol. Med.* 42, 119–20(1939).— Co salts injected into animals subjected to repeated bleedings or treated with C_6H_6 promote a rapid recovery from the anemia by stimulating the formation of erythrogenic precursors in the bone marrow. L. E. Gilson

Antihormone effects in pancreatic diabetes. F. C. Dohan and F. D. W. Lukens. *Proc. Soc. Exptl. Biol. Med.* 42, 167–71(1939).—Two completely depancreatized dogs injected with anterior pituitary ext. for 30 or more days showed, after cessation of injections, a much less severe diabetes during fasting than before the injections. Two other depancreatized dogs given intraperitoneal injections of serum from a dog treated over 9 months with anterior pituitary ext. showed a marked decrease in glucosuria, thus demonstrating the passive transfer of a principle antagonistic to the diabetogenic hormone of the anterior pituitary. Some expts. with cats are also reported. L. E. Gilson

Relation of concentrations of free to conjugated sulfapyridine in the blood of patients. Armine T. Wilson, Delores Kaely and Glenn E. Cullen. *Proc. Soc. Exptl. Biol. Med.* 42, 187–9(1939).—Patients show wide variation in blood content of free and total sulfapyridine when receiving standard dosage by wt. but the conjugated drug in most cases is present in about 2–3 mg. per 100 cc. blood. In a very few cases a high total level was accompanied by a high level of conjugated drug. L. E. Gilson

Action of apomorphine hydrochloride on the intact intestine in unanesthetized dogs. Chas. M. Gruber, Victor G. Haury and Miles E. Drake. *Proc. Soc. Exptl. Biol. Med.* 42, 193–7(1939).—When injected intravenously apomorphine may either increase or decrease the general tonus of the intact intestine. Large individual variations are found. L. E. Gilson

Central nervous system stimulant effects of *d*-amphetamine sulfate. Myron Prinzmetal and Gordon A. Alles. *Proc. Soc. Exptl. Biol. Med.* 42, 206–7(1939).—*d*-Amphetamine (*d*-benzedrine) is 2–4 times as active a stimulant as *l*-amphetamine and 1.5–2.0 times as active as *dl*-amphetamine (benzedrine). L. E. Gilson

Mechanism of estrogen effect on nasal mucosa in atrophic rhinitis; successful treatment with prostigmine. Samuel Soskin and L. B. Bernheimer. *Proc. Soc. Exptl. Biol. Med.* 42, 223–4(1939).—Preliminary note. L. E. Gilson

Nature of the pilomotor response to acetylcholine. Julius M. Coon and Stephen Rothman. *Proc. Soc. Exptl. Biol. Med.* 42, 229–31(1939).— In cats and man the local pilomotor or goose-flesh action after intradermal injection of acetylcholine is due to a nicotine-like action. Acetylcholine, nicotine and other drugs possessing nicotine-like action exert this influence through an axon reflex the receptor end of which has several properties characteristic of autonomic ganglia and the effector end of which is evidently adrenergic. **Nature of a sweat response to drugs with a nicotine-like action.** *Ibid.* 231–3.—Localized sweat secretion is provoked by intradermal injection of drugs with a nicotine-like action. It is accomplished through a peripheral axon reflex mechanism which is easily differentiated experimentally from the direct muscarinic action of acetylcholine on the sweat glands. L. E. Gilson

Comparison of different types of central stimulation from analeptics. J. W. Schulte, M. L. Tainter and J. M. Dille. *Proc. Soc. Exptl. Biol. Med.* 42, 242–8(1939).— The effects of metrazole, picrotoxin, coramine, caffeine and cocaine in rats are compared. L. E. Gilson

Colloidal sulfur to modify extirpation diabetes. Harry Greengard and Garr J. Burt. *Proc. Soc. Exptl. Biol. Med.* 42, 253–4(1939).—The administration (by stomach tube) of colloidal S in daily doses of 250–500 mg. had no effect on the diabetic state of the depancreatized dog. L. E. Gilson

Distribution and excretion of sulfapyridine in the guinea pig. Konrad E. Birkhaug. *Proc. Soc. Exptl. Biol. Med.* 42, 270–5(1939).—Orally administered sulfapyridine is almost completely absorbed from the guinea-pig stomach in 4 hrs. Very little passes into the intestine. The drug is distributed to every liquid, tissue and organ in the body, mostly in the free form. Graphs are presented showing the rise and fall in concn. in various fluids and tissues. About 70% of the ingested drug is excreted in the urine in 36 hrs. and resorption from the mucosa of the larger gut may account for the discharge of the rest of the feces. L. E. Gilson

Effect of cooling on the mechanism of insulin action. David B. Tyler. *Proc. Soc. Exptl. Biol. Med.* 42, 278–80(1939).—Insulin hypoglucemia is prolonged by cooling the animal. The survival period of rabbits receiving lethal doses of insulin was prolonged by cooling to body temps. of 25–30°. The cooling decreases metabolic activity. L. E. Gilson

Effect of spinal anesthesia on intestinal activity. C. L. Burstein. *Proc. Soc. Exptl. Biol. Med.* 42, 291–3(1939). —Procaine spinal anesthesia increases the amplitude of the intestinal contractions in the normal, unmedicated dog. L. E. Gilson

Sulfanilamide and sulfapyridine in treatment of experimental B. Friedländer (Klebsiella pneumoniae) infections of mice. John A. Kolmer and Anna M. Rule. *Proc. Soc. Exptl. Biol. Med.* 42, 305–7(1939).—The protective action of sulfanilamide was very slight. Sulfapyridine was somewhat more effective and saved about 25% of the infected mice. **Sulfanilamide and sulfapyridine in treatment of experimental Escherichia coli infections in mice.** *Ibid.* 307–9.—The protective action of either drug was almost negligible with the particular strain of *Es. coli* used. L. E. Gilson

Electrocardiographic changes in ethylene glycol poisoning. O. Leonard Huddleston. *Proc. Soc. Exptl. Biol Med.* 42, 312–15(1939).—Electrocardiograms of poisoned adult dogs and pups are shown. L. E. Gilson

Effects of morphine sulfate on hypothalamus of the cat. Jules H. Masserman. *Proc. Soc. Exptl Biol. Med.* 42, 315–17(1939).—Morphine caused little or no change in the sensitivity of the hypothalamus to elec. stimulation. L. E. Gilson

Effect of sulfanilamide on the isolated frog heart. W. L. Mendenhall and K. E. Shreeve. *Proc. Soc. Exptl. Biol. Med.* 42, 317–18(1939).—Dil. solns. produce a stimulation followed by depression. L. E. Gilson

Reduction in experimental rat caries by fluorine. Harold C. Hodge and Sidney B. Finn. *Proc. Soc. Exptl. Biol. Med.* 42, 318–20(1939).—Young rats fed a 30% casein diet contg. as little F as possible developed numerous carious teeth. Litter mates on the same diet but given 3 mg. F (as KF) daily developed few or no bad teeth. L. E. Gilson

Sulfapyridine potentiation of narcotic and toxic effects of papaverine in rats and rabbits. Susi Glaubach. *Proc. Soc. Exptl. Biol. Med.* 42, 325–7(1939).—Sulfapyridine potentiates the action of papaverine-HCl and often causes a therapeutic dose to produce death. L. E. Gilson

Decreased tolerance of mice to intraperitoneal glucose injections in certain neurotropic virus infections. Anson Hoyt, Margaret Holden and Ruth A. Rawson. *Proc. Soc. Exptl. Biol. Med.* 42, 332–6(1939).—Mice in the symptomatic stages of neurotropic virus infections (fixed rabies virus, a neurotropic strain of herpes, St. Louis encephalitis and Western equine encephalomyelitis) are much more easily killed by intraperitoneal glucose than normal mice. L. E. Gilson

Pharmacology of the venom of Bothrops jararacussu. Elda Pecciarini. *Boll. soc. ital. biol. sper.* 14, 427–9 (1939).—The venom is a protein with enzyme characteristics. In concns. greater than 1:100,000 it hemolyzes

blood and in concns. greater than 1:8,000,000 it completely coagulates oxalated or citrated blood *in vitro*. It first stimulates and then inhibits potato oxidase and has little effect on alc. fermentation. The M. L. D. for frogs is 0.3–0.5 mg., for rats 3 mg. given subcutaneously and for rabbits 0.80–0.1 mg./kg. given intravenously. Helen Lee Gruehl

Minimal doses of various drugs reacting on isolated frog or toad heart. I. Simon. *Boll. soc. ital. biol. sper.* **14**, 448(1939).—Folinerin (glucoside extd. from *Nerium oleander*) is active in concns. of 1:10 billions and quinine dihydrochloride in concns. of 1:2500 billions. Helen Lee Gruehl

Gastric elimination of sodium chloride and sodium sulfate after intravenous injection of hypertonic solutions of the two salts. I. Simon. *Boll. soc. ital. biol. sper.* **14**, 448–9(1939).—Under such conditions the vol. of urine eliminated exceeded the vol. of injected soln. while the amt. of salts eliminated was less. NaCl increased in the gastric contents, blood and all tissues. H. L. G.

Site of action of ergometrine. I. Antagonism with adrenaline. R. Senti. *Boll. soc. ital. biol. sper.* **14**, 459–61(1939).—In smooth-muscle expts. ergometrine acted differently from adrenaline and ergotamine. The sympathetic nerve endings were therefore excluded as the site of its action. Helen Lee Gruehl

Effect of eserine on the hypoglucemizing power of insulin. Luigi Liaci. *Boll. soc. ital. biol. sper.* **14**, 461–3(1939).—Eserine definitely increased the hypoglucemizing power of insulin. Helen Lee Gruehl

Sulfamine preparations in therapy of diseases of the biliary tract. Luigi Liaci. *Boll. soc. ital. biol. sper.* **14**, 463–4(1939).—*p*-Aminophenylsulfamine and *p*-succinylaminophenylsulfamide, administered orally or parenterally to rabbits, was found in greater concn. in the bile than in the blood. These substances proved efficacious in treating certain biliary diseases. H. L. Gruehl

Utilization of pyruvic acid in heart-lung preparations. P. Fornaroli and V. Capraro. *Boll. soc. ital. biol. sper.* **14**, 472–4(1939).—Pyruvic acid was almost completely utilized within an hr. This diminution was accompanied by a corresponding increase in lactic acid. H. L. G.

Glycogen and cardiac function. Piero Gomarasca. *Boll. soc. ital. biol. sper.* **14**, 476–7(1939).—In mice treated with caffeine the glycogen diminished in inverse ratio to the dose administered. Helen Lee Gruehl

Therapy of acute barbituric intoxication. Lanfranco Zancan. *Boll. soc. ital. biol. sper.* **14**, 490–3(1939).—Favorable antitoxic effects were obtained in rabbits by phleboclysis alone or combined with camphor, coramine, benzedrine or strychnine. The last 3 were the most effective. Helen Lee Gruehl

Pharmacology of the urinary tract. "Leonardo Donatelli. *Boll. soc. ital. biol. sper.* **14**, 498–500(1939).—Expts. on the effect of different concns. of adrenaline, sympathol, ephedrine, suprifen, veritol and benzedrine on rabbit urinary app. showed varying reactions in sphincter and detrusor activity. Helen Lee Gruehl

Chronic fluorine intoxication in domestic animals. A. W. Peirce. *Nutrition Abstracts & Revs.* **9**, 253–61(1939).—A review with 122 references. E. H.

The efficacy of chaulmoogra oil in the treatment of bovine paratuberculosis. Robert Graham, L. E. Boley and Norman D. Levine. *Cornell Vet.* **29**, 352–6(1939).—Results obtained in feeding chaulmoogra oil (8–99 oz. administered at the rate of 1–3 oz. weekly) to 61 cows that reacted positively to the paratuberculosis test indicated that this treatment has no effect on the results of subsequent paratuberculosis tests as compared with a control group. K. D. Jacob

Accidental phosphorus poisoning of a dog. H. D. Pritchett. *Cornell Vet.* **29**, 391–4(1939).—A case report on an animal that completely recovered from the effects of ingestion of approx. 6 grains white P in the form of a rat paste. K. D. Jacob

The origin of acetylcholine contracture. II. Conditions underlying the origin of twitches and contracture upon administration of acetylcholine. S. P. Narikashvili. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 286–8(1939)(in English); cf. *C. A.* **34**, 5283.—Preliminary treatment of muscles with isotonic NaCl soln. increases the effect of acetylcholine (I), nicotine and lactic acid on the muscle, apparently by increasing membrane permeability and allowing rapid penetration of the substances. Isotonic $CaCl_2$ solns. decrease permeability and inhibit the effect of I. S. A. Karjala

The influence of antipyrine on reflex gastric secretion under various modes of application. S. Sh. Sakanyan. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 312–14(1939)(in English).—Antipyrine exerts a sharp local irritating action when administered either *per os*, hypodermally or *per rectum*. Intravenous injection is the most satisfactory method of administration. S. A. Karjala

Changes in the velocity of blood in the lesser circulation and in the temperature of subcutaneous tissues in rabbits after poisoning by inhalation of nitric oxide. A. T. Timofeev. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 308–11(1939)(in German).—The inhalation of NO by rabbits results in dyspnea, with a decrease in the alk. reserve of blood by 12–54% in 3–5 hrs., a 2–6-fold reduction in the complement titer in 24 hrs., a decrease in body temp. of 0.5–3.6°, a decrease in the velocity of blood in the pulmonary circulation and a decrease in the temp. of subcutaneous tissue amounting to 1.3–5.4°. S. A. K.

The role of lung tissue in the destruction of the adrenaline circulating in the blood. G. E. Batrak. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 426–9(1939)(in German).—The injection of adrenaline (I) into the pulmonary artery of the isolated heart-lung system of dogs gives the same rise in blood pressure as injection of I into the left heart chamber, indicating that lung tissue does not destroy I in circulating blood. S. A. Karjala

The significance of the dissimilar sensitivity of acetylcholine and cholinesterase to parabiotic agents. O. V. Seidlits. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 432–5(1939)(in English).—In the presence of a parabiotic agent ($CHCl_3$, cocaine, PhOH or strychnine) no change was observed in the action of acetylcholine (I) in frog blood serum even after 1–1.5 hrs. of exposure. Cholinesterase was inhibited, resulting in a 30–50% decrease in the destruction of I, the resulting accumulation of I then being responsible for the parabiosis of the altered nerve region. NH_3 increases the effect of I. S. A. Karjala

The influence of tetanus toxin on the regulatory function of the hematoencephalic barrier. A. Yakovchuk. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 461–5(1939)(in French).—The subcutaneous injection of 400–1600 M. L. D. of tetanus toxin into dogs results in an immediate slight drop in K in the serum and cerebrospinal fluid, followed by a rise above normal. The Ca decreases on the 2nd–3rd day after injection and then slowly returns to normal. Inorg. P shows a steady increase with the course of the disease. No change was observed in Cl. The K/Ca ratio in the cerebrospinal fluid decreases at the onset, but with progress of the disease it gradually increases. Essentially the same results were obtained after intravenous injection of the toxin. S. A. Karjala

The effect of insulin on gastric secretion. N. G. Lesnoi and S. N. Nikolaichuk. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 483–5(1939)(in English).—The injection of 0.5 I. U. of insulin (I) into gastroesophagotomized dogs when the gastric glands were in a quiescent state induced marked gastric secretion with a high digestive power (Mett) and acidity. Nervous (reflex) stimulation 2 hrs. after the injection of I caused a sharp drop in the amt. of juice, a decrease in free HCl and a slight increase in digestive power. Humoral stimulation by injection of 0.5 mg. of histamine before I injection caused a large increase in juice secreted, with slight increases in acidity and digestive power. S. A. Karjala

Changes in blood complement in rabbits after poisoning by inhalation of nitric oxide. A. T. Timofeev. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 478–82(1939)(in German).—The inhalation of NO by rabbits results in a sharp drop in blood complement, which returns to normal after recovery. S. A. Karjala

The influence on the animal of thyroid metabolites introduced into the cerebral ventricles. I. Their influence on the composition of the blood and cerebrospinal fluid. G. N. Kassil, T. G. Plotitsina and Ch. Volkovis-skaya. *Bull. biol. méd. exptl. U. R. S. S.* **8**, 51–5(1939) (in French).—The injection of thyroid metabolites and thyroxine (I) into the cerebral ventricles of dogs results in a reduction in the K/Ca ratio and a decrease in P in the cerebrospinal fluid and blood. I also lowers the concn. of reducing substances in the fluid and blood serum. The injection of diiodotyrosine (II) causes a lowering in K, Ca, P and K/Ca in the blood and a lowering in K and Ca with an increase in P and a slight increase in K/Ca in the cerebrospinal fluid. The injection of small doses of metabolites, I or II directly into the blood stream results in an increase in reducing substances, P and K/Ca. S. A. Karjala 1

4,5-Dimethylaspirin. Leonhard Birkofer. *Z. physiol. Chem.* **261**, 87–92(1939).—4,5-Dimethylaspirin (I) is less toxic to rabbits and has the same antipyretic and analgesic actions as aspirin. I, m. 122°, was prepd. by acetylation of 4,5-dimethylsalicylic acid (II), Me ester of II m. 33°, phenol ester m. 85°, Me ester of I m. 74 5°. Milton Levy 2

The effect of metrazole by perlingual and enteral administration. H. Kuschel. *Klin. Wochschr.* **18**, 1131 (1939). Metrazole is readily absorbed by the mucosa of the tongue and gastrointestinal tract. The duration of the effect is about 3 times that following intravenous injection. H. L. Mason 3

Sulfanilamides, especially sulfapyridine Eubasinum, in the treatment of epidemic meningitis; their theoretical importance, ability to pass into the cerebrospinal fluid and results of their use. Gerhard Säker. *Klin. Wochschr* **18**, 1141–5(1939).—The successful results of treatment of meningitis with Eubasinum are due to the ease with which this substance passes into the cerebrospinal fluid. Prontosil album and sulfanilamide also possess this property. Uliron, a sol. hexose sulfamide, and the Na salt of Eubasinum penetrate with such difficulty that satisfactory concns. cannot be attained. H. L. Mason 4

Fractionated doses of medicinal substances injected at short intervals in experimental trypanosomiasis. L. Launoy. *Bull. acad. méd.* **121**, 550–6(1939).—Repeated small intravenous doses lead to a tolerance of larger total quantities of the therapeutic agent than when a single dose is given. At a given dose of Sb in mice infected with trypanosomes the survival no. was increased from 32.4 to 84.6%. The substances used were Na orsammine and anthiomaline (Li-Sb-thiomalate). A. E. Meyer 5

The mechanism of chemotherapeutic action of some sulfur-containing aromatic compounds in infections with Friedländer bacilli. C. Levaditi, A. Vaisman and D. Krassnoff. *Bull. acad. méd.* **121**, 730–50(1939). The compds. tested were p-sulfaminophenylazosalicylic acid, 4-nitrodiphenylsulfone - 4′ - azo - 2 - naphthol - 3,6-disulfonate of Na and 4-nitrodiphenylsulfone-4′-azo-7-acetylamino-1-naphthol-3,6-disulfonate of Na. All 3 substances were effective. The primary effect, as tested in mice, was production of involutive changes in the microbes and interference with the formation of capsules and multiplication. The second effect was increased phagocytosis. The capsule is a protective coat which makes the virulent germ resistant to phagocytosis. A. E. Meyer 6

Clinical studies on the mechanism of the action of β-(*p*-hydroxyphenyl)isopropylmethylamine (veritol). Gaspare Pona and Filippo Muratori. *Acta Med. Scand.* **101**, 465–81(1939).—Although the blood-pressure-raising effect of veritol is a complex phenomenon, the direct action on the heart muscle plays a fundamental part. In addn. there is probably a vasoconstrictor effect and mobilization of blood from the depots. S. Morgulis 7

Studies on man of the constipating action of morphine, opium and of an opium preparation of the pantopon type. Nils Alwall. *Acta Med. Scand.* **101**, 419–32(1939).—A no. of healthy, vigorous medical students served as subjects. The drugs were administered in pills before retiring. Blank pills were also used, and subjects had no knowledge of the nature of the pill administered. The doses were as follows: 10 mg. morphine-HCl; 20 mg. "Pantopon," and 1 g. tincture of opium. A constipating effect was found in 20% of the cases after morphine, and in 40% after the other drugs. With a double dose the effect manifested itself in 50%, and 70–75% of the subjects. The constipating effect lasted 1–1½ days. S. Morgulis 8

Treatment of exogenous pellagra with stomach preparations, and considerations on the possible identity of the vitamin B_2 complex with the "cyanide insensitive enzyme complex." Erik Bandier. *Acta Med. Scand.* **101**, 496–510 (1939).—A study was made on a no. of patients (Rumanian peasants) suffering from nutritional pellagra; a combination of stomach prepns. (ventriculin, pylorin or fundin) was used with HCl. The results, manifested by a prompt beneficial effect on the gastro-intestinal symptoms, mucous membranes, appetite and general condition, were as remarkable as in endogenous pellagra. It is pointed out that exptl. studies have revealed that, besides nicotinic acid and riboflavin, certain amino acids are also essential to obtain therapeutic results in pellagra. The idea is developed that the vitamin B_2 complex may be identical with the so-called "cyanide insensitive system" of enzymes which comprises the yellow respiration enzyme (a protein mol. bound to a *d*-riboflavinphosphoric acid), cozymase (a di- or tri-phosphopyridine nucleotide contg. *d*-ribosephosphoric acid and nicotinic amide) and finally the intermediate enzyme consisting of special proteins. This idea is supported by the observation that the cozymase content of blood in pellagrins is low but is increased on the administration of nicotinic acid. On this view the pellagra condition would be regarded as an enzyme deficiency. S. Morgulis 9

Successful treatment of giardiasis in man with Acranil—a hydrochloride of a new acridinic compound. Paolo de Muro. *Acta Med. Scand.* **102**, 17–21(1939).—Acranil has proved itself an efficient parasiticide against the trophozoit *Giardia intestinalis*, and produced no toxic symptoms. S. Morgulis 10

Disturbance of sugar metabolism in acute carbon monoxide poisoning. Sven Moeschlin. *Acta Med. Scand.* **102**, 140–59(1939).—In 57% of the patients suffering from CO poisoning there was a marked rise in the blood sugar, up to 390 mg. %, which usually persisted for 1–2 days. In one case it lasted 8 days. Although the hyperglucemia was more common among the severe cases of intoxication, no relation exists between the degree of intoxication and the degree of hyperglucemia. Glucosuria was found in only 17%, and the urinary diastase was not increased. In about two-thirds of the samples of cerebrospinal fluid examd. there was a definite increase in sugar. S. Morgulis 11

Effect of thyroxine on the rat hypophysis. André Neuhaus. *Endokrinologie* **22**, 90–112(1939).—In male rats, made hyperthyroid by injection of thyroxine, the hypophysis showed degenerative changes in the chromophile cells. In the basophile cells the alterations were less pronounced. The changes are similar to those observed in the hypophyses of patients with Basedow's disease. S. Morgulis 12

Morphologic changes in the ovaries of infantile rats under long administration of prolan. Werner Reiss. *Endokrinologie* **22**, 112–36(1939).—Long administration of prolan to young rats causes the corpora lutea to persist. At first, the prolan treatment produces violent reactions with massive formation of corpora lutea and inhibition of follicle development, but this is followed by a stage, lasting 24 to 72 days, free from reaction during which the corpora lutea undergo regression. Then the reaction starts once more, marked by an irregular cycle, with the formation of large ripe follicles and new corpora lutea. This suggests that antibodies to prolan are formed, and so long as they are not in excess the prolan maintains the corpora lutea and thus prevents the ripening of new follicles. But 13

when the antibodies are in excess, the prolan effect is abolished, the old corpora lutea disappear and follicles ripen under the influence of the gonadotropic substances produced by the hypophysis of the animal which meanwhile has attained sex maturity. This occurs usually at a larger wt. in treated animals (103 g.) as compared to that of controls (80 g.). However, the first spontaneous estrus occurs in either at about 8–9 weeks. S. M.

Hyperinsulinism. R. Thomae. *Münch. med. Wochschr.* **86**, 1261–4(1939).—Observations of a type of sugar-deficiency disease based on an island cell adenoma are described. T. reports mild, moderate and severe hypoglucemic episodes. The mild attack is characterized by sensations of hunger, sudden sweats, visual disturbances, fatigue and irritability. Severe attacks are accompanied by threatened collapse, fainting, temporary paralysis and blindness. In treating such conditions, T. recommends a diet in which numerous small meals with high carbohydrate content are given. Insulin, although seemingly paradoxical, is recommended. T. reasons that the exogenous administration of insulin induces hypofunction of the insular cells. A diet with a high fat content and injection of insulin after every meal gave encouraging results. T. reports hypoglucemic attacks are more frequent than realized and he suggests that sugar metabolism be investigated in patients with repeated attacks of fainting, as well as of persons, particularly children, who are easily fatigued. Maurice M. Rath

Effect of rectally administered insulin suppositories in diabetic patients. F. Wuhrmann. *Schweiz. med. Wochschr.* **69**, 787–9(1939).—Blood-sugar curves of 14 diabetic patients and of 4 normal subjects were studied after the rectal administration of insulin suppositories. One suppository unit was made equal to 10 injection units. W. concludes that measurable and effective quantities of insulin can be administered in this manner. Less-refined forms can be employed since the presence of protein substances does not constitute a hindrance. M. M. R.

Chemical observations in toxic conditions. G. Francom. *Schweiz. med. Wochschr.* **69**, 921–7(1939).—Lecture describing toxic conditions in hypoglucemia, spontaneous hypoglucemia, diabetes mellitus, hypochloremic conditions, hypocholesteremenia, hypo- and hyperphosphatemia. Maurice M. Rath

The effect of sodium bromide on the nutrition and the gastrointestinal tract of epileptic patients. Alex J. Arieff. *J. Lab. Clin. Med.* **25**, 19–24(1939).—Few toxic cases were observed in these patients with blood bromide concns. around 200 mg. per 100 cc. When there was no anorexia or bromide toxicosis producing an inadequate caloric intake, this blood level caused no wt. loss, had no effect on nutrition and produced no abnormal change in the basal metabolic rate. Gastric analyses showed that the chloride ion was displaced by bromide from 25 to 50%. In expts. *in vitro* HBr slightly retarded peptic digestion but not enough to produce clinical symptoms and had no effect on tryptic digestion. Howard W. Robinson

An experimental study of the rectal administration of mercurial diuretics. I. J. Brightman and Robert A. Lehman. *J. Lab. Clin. Med.* **25**, 56–66(1939).—An exptl. procedure was developed to study the toxicity, Hg absorption and excretion in cats who had received salyrgan or mercurin suppositories, and salyrgan suppositories modified by the addn. of theophylline or the acid of salyrgan. The results obtained with the various prepns. are compared and the lesions which they may produce in the colon of the cat are described. H. W. R.

Effect of thyroglobulin and thyroxine on the oxygen consumption of tissues in vitro. Attilio Canzanelli, Ruth Guild and David Rapport. *Endocrinology* **25**, 707–11(1939).—At lower levels of metabolism thyroglobulin stimulates the O consumption of guinea-pig kidney, testis and heart. There is a ceiling above which thyroglobulin can no further elevate the O uptake, and this ceiling is higher, in the case of kidney and heart, in serum than in a salt buffer mixt. Thyroxine generally had no stimulating effect in either the salt buffer mixt. or the serum. In 2 expts. in serum a stimulating effect appeared, raising the possibility that thyroxine under certain circumstances may be made physiologically active by contact with serum. Felix Saunders

Relief of myxedema with proteins of extrathyroidal origin. J. Lerman and W. T. Salter. *Endocrinology* **25**, 712–20(1939).—Successful responses in myxedema and cretinism and thyroidectomized rabbits were produced by iodinated serum protein and its acid-insol. degradation products. This material was produced by the brief treatment of blood proteins with compd. soln. of I. In terms of total mass, the activity of the iodoprotein was about 20% of that of whole thyroid; in terms of I, the activity was about 1/400. The acid-insol. iodopeptone was about one-half as active as whole thyroid in terms of total mass, but only 1/200 as active in terms of I. The material can be fractionated by enzymes or by alk. hydrolysis into thyroxine-like (*T*) and into diiodotyrosine-like (*D*) fractions. All the activity of the original protein is in *T*. *D* yields no thyroxine-like amino acid after drastic treatment with hot $Ba(OH)_2$ soln., whereas *T* yields, under such treatment, material which resembles iodothyroxine derivs. Felix Saunders

The effect of chronic opium and narcotic habits on the female genital organs. V. Growth of fetal and suckling mice born of mothers with opium habits. T. R. Ko. *J. Oriental Med.* **31**, 333–44(German abstr. 28)(1939); cf. *C. A.* **34**, 1729.—The growth is greatly retarded, and puberty is delayed. **Supplement. Chemical and biological studies of crude opium.** *Ibid.* 345–51(German abstr. 29).—The crude opium used in these expts. contained 21% morphine and 3.75% H_2O. Comparative studies were made between this crude opium and pure morphine in amts. corresponding to that contained in the crude opium, as to tail-lifting dosages, the duration of the maintaining positions, and death dosages. S. T.

Nature of the pressor action of renin. Irvine H. Page. *J. Exptl. Med.* **70**, 521–42(1939).—Tachyphylaxis occurs when renin is repeatedly injected into dogs and cats regardless of whether they are normal, anesthetized, pithed, hepatectomized, suprarenalectomized, nephrectomized or eviscerated. The pressor response of renin in brief expts. is independent of the height of the arterial pressure or the presence of the suprarenals. Evisceration and large doses of ergotamine reduce the response. It is largely uninfluenced by pithing, intracisternal injection of renin, cocaine, strychnine, caffeine and infusion of $NaHCO_3$ or HCl. It may be slightly increased by large blood transfusions or hepatectomy, but the result is short lived. There is no parallelism between the pressor responses to carotid sinus stimulation, adrenine and tyramine on the one hand and renin on the other. Intracisternal injection of renin elicits no significant rise in blood pressure or other circulatory manifestations. Renin alone causes no vasoconstriction when perfused with Ringer soln. but renin plus renin-activator restores activity. Renin tachyphylaxis is due to loss of renin-activator and development of an "anti-substance" (antipressor state or loss of some substance necessary for the chem. reactions which culminate in the pressor action of renin) in the blood. C. J. W.

Effect of histaminase treatment on histamine and anaphylactic shock in guinea pigs. S. Karády and J. S. L. Browne. *J. Immunol.* **37**, 403–8(1939).—The intravenous injection, in guinea pigs, of histaminase 15 min. before the intraäbdominal injection of 4 mg. of histamine, prevented in most instances the symptoms of histamine shock. Also similar treatment prevented shock after the administration of egg white to previously sensitized guinea pigs. Charles A. Zittle

Compn. of the fruits of *Mespilus germanica* [use in dysentery] (Sartory, *et al.*) **12**. *Pseudocinchona africana*—therapeutic utilization (Raymond-Hamet) **17**. Sulfanilamide derivs. (Crossley, *et al.*) **10**. Chemistry and chemotherapy of 4,4′-diaminodiphenyl sulfone, 4-amino-4′-hydroxydiphenyl sulfone and related compds. (Raiziss, *et al.*) **10**. Derivs. of aminomethanethiol [pharmacol. effect] (**Binz, Pence**) **10**.

I—ZOÖLOGY

R. A. GORTNER

Studies on the reproductive system of the alligator. V. Effect of injections of testosterone propionate in immature alligators. Thomas R. Forbes. *Anat. Record* **75**, 51–7 (1939); cf. *C. A.* **33**, 2442,3. Philip D. Adams

Phosphatase of the bone and growth of the skeleton in the sardine (Clupea pilchardus Walb). Jean Roche and Jacqueline Collet. *Compt. rend.* **209**, 530–2 (1939).—Measurement of the phosphatase activity of different parts of the skeleton in different stages of development of the sardine shows that this enzyme plays an important part in rapid osteogenesis but only a secondary role in slow ossification. Rachel Brown

Effect of alkaloids of the veratrine group. Z. M. Bacq. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 232–3 (1939).—Veratrine sensitizes the muscles of many classes of invertebrates to the action of ions of the K family and to Ba. Aconitine has a similar effect on muscle to that of veratrine except in the Coelenteres and Echinodermes. E. Curzon

Use of acid dyes in studying the problems of permeability. Observations on the alevin of the trout. R. Cordier. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 236–9 (1939).—The diffusibility and dialyzability of the dyes used markedly affect the results obtained as to the permeability of the membranes. E. Curzon

Functional metabolism of the melanocytes of frog skin. Jan Belehradek. *Compt. rend. soc. biol.* **132**, 20–2 (1939); cf. *C. A.* **32**, 2049.—Expansion of the melanophores is dependent on some process of anaerobic glucolysis. KCN stops all aerobic respiration but does not hinder the expansion of the melanophores provoked by pituitrin. Possibly the pigment granules receive an elec. charge which causes them to repel each other and scatter. Very dil. CH_2ICO_2H inhibits the action of pituitrin and adrenaline on the melanophores. L. E. Gilson

Relation between amphibian water-retention principle and oxytocic activity of pituitary extracts. Eldon M. Boyd and Edward G. Mack. *Proc. Soc. Exptl. Biol. Med.* **42**, 70–3 (1939); cf. *C. A.* **33**, 3467.—Twelve com. lots of posterior pituitary ext. contained 4–10 times as many amphibian water-retention units per ml. as international oxytocic units. The method of estn. is described. L. E. Gilson

Hydrolysis of acetylcholine by turtle blood. J. M. Little. *Proc. Soc. Exptl. Biol. Med.* **42**, 197–200 (1939).—Laked whole blood of *Pseudemys elegans* has considerable cholinesterase activity while the plasma has little or none. Prostigmine completely inhibits the activity of laked blood. Unlaked whole blood has 18–59% more activity than laked whole blood and this extra activity is not inhibited by prostigmine. L. E. Gilson

Estrogenic properties of extracts of ovaries of certain marine invertebrates. J. K. Donahue. *Proc. Soc. Exptl. Biol. Med.* **42**, 220–2 (1939).—Sexually mature ovaries of sea urchins (*Lytechinus variegatus* and *Echinometria*), holothurians (*Stichopus mobii*) and lobsters (*Palinurus argus*) from Bermuda contained small amts. of estrogenic substances extractable by alc. L. E. Gilson

Effects of administering mouse anterior pituitary to the newt and frog. A. Elizabeth Adams, Elizabeth M. DeForest and Barbara Granger. *Proc. Soc. Exptl. Biol. Med.* **42**, 354–9 (1939).—*Triturus viridescens* (a newt) ovulated out of season after implants of mouse anterior pituitary averaging 12.6 mg., although the reaction was slower and less complete than after approx. 0.84 mg. of newt whole pituitary. In *Rana pipiens* implants of 35–230 mg. mouse anterior pituitary produced no ovulatory response. L. E. Gilson

Specific morphoses in Drosophila induced by chemical compounds. J. A. Rapoport. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 415–17 (1939) (in English).—Sublethal doses of HgI_2, $HgSO_4$ and $HgCl_2$ in the nutrition medium of *Drosophila melanogaster* at the egg or larval stage produce the minute morphosis. Slightly sol. Hg compds. (cinnabar) give no morphoses. $SbCl_3$, $K_4Sb_2O_7$ and $SbCl_5$ produce lighter eyes of the brown or light type with changes in body color and wing structure resembling the mutation "ski." The H_3AsO_4, $(CH_3)_2AsO_2Na$, atoxyl, arsphenamine and neoarsphenamine morphoses resemble the tumor mutation. Compds. of B produce morphoses which resemble the mutation eyeless, while Ag lactate and other Ag compds. cause a marked bleaching of body color similar to the yellow mutation. NH_4CNS, KCNS, NaCNS and $Cr_2K_2(SCN)_{12}$ cause a marked shortening of the pupa and K_2SeO_4 and $(NH_4)_2SeO_4$ produce morphoses similar to the mutation "abdomen abnormal." Colchicine changes the eyes to those of the mutation "rough." S. A. Karjala

Acetylcholine contracture of the muscles of invertebrates. S. P. Narikashvili. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 283–5 (1939) (in English).—The threshold concns. of acetylcholine (I) and nicotine (II) for contracture of the smooth muscles of the invertebrates *Arenicola marina*, *Cucumaria frondosa* and *Styela rustica* are $1:10^6$ and $1:10^7$, $1:10^7$ and $1:20$, and $1:10^8$ and $1:125$, resp. The circular muscle of *Cyanea arctica*, the adductor of *Pecten islandicus* and the muscles of the segments and claws of *Hyas araneus* were insensitive to I and II. All of the invertebrate muscles were insensitive to lactic acid and $CHCl_3$. S. A. Karjala

Discharge of an acetylcholine-like substance by the isolated frog heart treated with adrenaline. M. Ya. Mikhel'son. *Bull. biol. méd. exptl. U. R. S. S.* **7**, 289–91 (1939) (in English).—The isolated heart of *Rana temporaria* begins to excrete an acetylcholine-like substance 7–12 min. after the injection of adrenaline. S. A. Karjala

Changes of inheritance characteristics through chemical influence. H. Dotterweich. *Umschau* **43**, 783–6 (1939).—A brief discussion of the work done in connection with the Timofeéff-Ressovsky, Zimmer and Delbrück view of the stability of the atom structure of genes and the effect on the spontaneous mutation rate of *Drosophila* in various nutritions media—i. e., solns. of hypophysis, progynon, sea water, vitamin C and tincture of Jaborandi. H. K.

Demonstration of the melanophore hormone in the fish hypophysis. Hans H. Meyer. *Endokrinologie* **22**, 137–44 (1939).—An aq. ext. from the hypophyses of *Gadus morrhua* contains a substance which frequently causes an expansion of the chromatophores of various fishes. This could be best demonstrated with the flat fish. It is active even after the destruction of the central nervous system. The ext. causes the fish to darken after a preliminary bleaching. S. Morgulis

Crystalline echinochrome and spinochrome: their failure to stimulate the respiration of eggs and of sperm of strongylocentrotus. Albert Tyler. *Proc. Natl. Acad. Sci. U. S.* **25**, 523–8 (1939).—Ground sea urchin testes are extd. with neutral alc. and then Et_2O. The test material is then added slowly to 0.5 *N* HCl under Et_2O. The Et_2O ext. is dried and filtered through a column of $CaCO_3$. Two layers are formed; the upper layer contg. *spinochrome* (I), m. 187–8°, the lower layer *echinochrome* (II), m. 220–1°. I and II are present as Ca salts in the test of the sea urchin. Solns. of I and (or) II produced no change in the rate of O_2 consumption when added to unfertilized sea urchin eggs in sea water, or in Ca-free sea water at pH 8. The rate of O_2-uptake of sea urchin spermatozoa is not affected by 10γ/cc. of I or II in ordinary sea water (buffered), but the rate is definitely inhibited by high concns. (10 mg./cc.). W. J. Peterson

Comparative value of pollen and pollen substitutes. I. Bee bread and cottonseed meal-dry skim milk mixtures. Mykola H. Haydak. *J. Econ. Entomol.* **32**, 663–5 (1939).—Colonies of honeybees fed a mixt. of 4 parts by wt. of cottonseed meal and 1 part dry skim milk (spray process) equaled in resp. of development of the bees, no. and quality of the bees reared and in mortality of the bees those colonies which were fed the natural bee bread. C. H. R.

Nutritive value of certain foods for the adult honeybee. R. M. Melampy and S. E. McGregor. *J. Econ. Entomol.* **32**, 721–5 (1939).—A carbohydrate diet such as honey or invert sirup is inadequate for the newly emerged adult bee. In lab. expts., fresh pollen was a better supplement to a carbohydrate diet than any cereal or milk product

used. A low relative humidity and reasonably high temp. are conducive to long life of adult bees under controlled conditions. C. H. Richardson

Action of certain stimulating and inhibiting substances on the respiration of the grasshopper embryo, Melanoplus differentialis. Loren D. Carlson and Joseph H. Bodine. *J. Cellular Comp. Physiol.* **14**, 159–72(1939).—The rate of O consumption of diapause and postdiapause grasshopper embryos is altered by the addn. of pyocyanine and various respiratory inhibitors either separately or in combinations. The addn. of 10^{-3}–10^{-4} *M* pyocyanine to diapause embryos increases the rate of O consumption. The increase over the normal diapause level of respiration is 100–30%, and over the normal postdiapause, 60–100%. The increase in rate of O consumption due to pyocyanine is independent of the action of the inhibitors used, i. e., the pyocyanine increment is approx. the same for the inhibited and control embryos. The R. Q. of the embryo inhibited by any one of the various inhibitors was increased in all cases. The R. Q. for the embryo stimulated by pyocyanin is 0.89. When embryos inhibited by carbamate or veronal are treated with CO_2, there is little or no further inhibition. The pyocyanine increment for material treated in such a manner is similar to that for controls. F. Saunders

Enzymes in ontogenesis (Orthoptera) VIII. Changes in the properties of the natural activators of protyrosinase during the course of embryonic development. Joseph H. Bodine, O. Malcolm Ray, Thomas H. Allen and Loren D. Carlson. *J. Cellular Comp. Physiol.* **14**, 173–81(1939); cf. *C. A.* **33**, 7906[3].—The potency of a naturally occurring activator of protyrosinase decreases during particular periods of the embryonic development of the egg of the grasshopper, *Melanoplus differentialis*. There is no direct relation between the vol. of the lipoidal material with which it is associd. and the potency of the activator. **IX. Influence of various solutes on the activity of tyrosinase.** Thomas H. Allen and Joseph H. Bodine. *Ibid.* 183–8.—Three prepns. of tyrosinase from the eggs of *M. differentialis* vary in the presence of a NaCl soln. with respect to their ability to catalyze the tyramine HCl-melanin reaction at 25°. The activities of 2 of these prepns., "heat" tyrosinase and "Na oleate" tyrosinase, decrease logarithmically through a certain range of increase in concn. of this NaCl soln. The activity of "heat" tyrosinase is characteristic, irrespective of the solute concn., for the particular kind of electrolyte or nonelectrolyte. Felix Saunders

Partition of nitrogen in the developing eggs of Urechis caupo. N. H. Horowitz. *J. Cellular Comp. Physiol.* **14**, 189–95(1939).—The eggs and embryos of the marine worm, *U. caupo*, were analyzed for total nonprotein, amino peptide NH_2 and amide N at several stages of development. No change in total N was found during the first 24 hrs. of development. At this time the egg has developed into a swimming larva. A decrease in total N occurs at the 30th hr. of development. This decrease corresponds with the onset of feeding by the larvae. Synthesis of protein, amounting to 6.4% of that present in the unfertilized egg, occurs during the first 24 hrs. of development. The ratio of protein to nonprotein N is higher in the tissues of the adult than in the embryonic stages studied. Felix Saunders

Electrolytes in the axoplasm of the giant nerve fibers of the squid. Richard S. Bear and Francis O. Schmitt. *J. Cellular Comp. Physiol.* **14**, 205–15(1939).—Direct analytical studies of the total solids, total base, K, Cl, N (total, protein and nonprotein) and total P of the axoplasm of squid giant fibers show (1) the internal K concn. of these fibers is 18 times as great as that of squid blood (2) There are considerable osmotic and elec. deficiencies within the axoplasm, the total known ion concn. being 63 and 71%, resp., of that found in blood and sea water. Cations are present in a concn. 4 5 times that of the known anions (chiefly Cl). (3) The cation excess (about 0.5 *N*) is too great to be balanced by common anions, such as HCO_3, OH, SO_4, HPO_4 and lactate. The protein present is also insufficient to supply the anion deficiency. Conclusion: Axoplasm must contain rather large amts. of unknown org. anions of moderate mol. wt. (4) The Cl-ion concn. is 0.13 milliequiv. per g of axoplasm water. Felix Saunders

Activity of protozoa at low oxygen tensions. J. A. Kitching. *J. Cellular Comp. Physiol.* **14**, 227–36(1939).—The contractile vacuole of the peritrich ciliates *Cothurnia kellicottiana* (from fresh water) and *Zoothamnium* sp (from brackish water) rapidly stopped all activity in pure H. On readmission of sufficient O there was a rapid recovery of activity. No correlation was found between the min. O tensions necessary for activity of protozoa and sensitivity of these organisms to cyanide. Felix Saunders

Comparative permeability to water and certain solutes of the egg cells of three marine invertebrates, Arbacia, Cumingia and Chaetopterus. Baldwin Lucké, H. Keffer Hartline and Renato A. Ricca. *J. Cellular Comp. Physiol.* **14**, 237–52(1939). Felix Saunders

Second intermediate host of Clonorchis sinensis in the Mukden area. Sukio Miyanaga. *J. Oriental Med.* **31**, 565–8(English abstr. 43)(1939).—Of 15 species of freshwater fishes of the Mukden area, 6 species (*Carassius auratus, Hemiculter clupeoides, Leucogobio herzensteini, Pseudogobio rivularis, Pseudorasbora parva*, and *Rhodeus notatus*) were found to be infected with cysts. of *Clonorchis sinensis*. S. Tashiro

12—FOODS

H. A. LEPPER

A fluorometric method for determining the riboflavin content of foodstuffs. A. Z. Hodson and L. C. Norris. *J. Biol. Chem.* **131**, 621–30(1939).—A fluorometric method for detg. the riboflavin content of foodstuffs is described which gives results in good agreement with those secured by the microbiol. method of Snell and Strong (*C. A.* **33**, 6371[9]). A. P. Lothrop

Pyrophosphates in foodstuffs. Louis Weil. *Ann. fals.* **32**, 250–2(1939).—A brief discussion of the use of pyrophosphates in baking powders. Attention is drawn to the necessity of studying the action on the human system of unchanged pyrophosphate residues in cakes, etc. A. Papineau-Couture

Fructose as a food. Erik M. P. Widmark. *Kgl. fysiograf Sallskap. Lund, Forh.* **7**, 22–31(1937)(Pub., 1938).—A lecture, including a discussion of the com. production of fructose (I), especially from the tubers of the Jerusalem artichoke, (*Helianthus tuberosus*), and the biol. properties and use of I as a substitute for cane sugar. I is suitable for use in the diet of diabetic patients. Because of the higher osmotic pressure and sweetening power of its solns. less I than sucrose is required in preserving. Marmalades, jams and marzipan do not crystallize when made with I. A possible drawback to the use of I is the ease with which it ferments. Ruth Berggren

Report on the quality, for bread-making purposes, of wheats harvested in 1938 at the headquarters and substations of the National Institute of Agricultural Botany. E. A. Fisher. *J. Natl. Inst. Agr. Botany* **4**, 372–88 (1939).—The customary chem. analyses of the wheats and flours are tabulated and results of baking tests are given K. D. Jacob

Quality tests on hard, red winter wheats. R. K. Larmour, E. B. Working and C. W. Ofelt. *Cereal Chem.* **16**, 733–52(1939).—Data show that within a given season the potential strength of the principal hard, red winter wheat varieties is related to protein content in linear fashion, and is highly correlated with it. It is shown that it is possible to obtain an expression of baking strength by means of a single formula applied under one set of fixed conditions. The formula involves the use of yeast 2, sugar 6, dry milk solids 6, $KBrO_3$ 0.004 and shortening 3%

with mixing to optimum consistency and using the standard fermentation and proof times of the A. A. C. C. Mixing curves obtained by the Swanson-Working instrument reveal certain marked distinctions between varieties within the hard winter wheat class as well as within varieties in the class. The greatest usefulness of the mixing curves provided the protein content is known is to characterize the type to which the flour belongs. L. H. Bailey

The amount of vitamin B_1 and B_2 (riboflavin) in ordinary Norwegian cereals and bread. Gulbrand Lunde, Hans Kringstad and Alf Olsen. *Nord. Med.* **3**, 2533 8(1939).—B_1 was detd. biologically (bradycardia method) and chemically (thiochrome method). B_2 was estd. colorimetrically. The following values in γ per g. were found for B_1 and B_2, resp.: 73% wheat flour 0.90, 0.40; wheat (wholemeal) 3.90, 1.40; wheat bran 5.85, 2.80; wheat germ 2.60, 4.40; 65% rye flour 1.89, 0.60; rye bran 5.25–6.30, 3.10; rye (wholemeal) 4.20, 1.60; oats (wholemeal), on an av., 4.55, 2.20; oats bran 3.75, 2.60; barley, on an av., 5.50, 3.00. Forty % wheat flour had 0.96, rolled oats 2.73, maize 5.40, white bread 0.63, wholemeal bread 1.89, rye bread, ordinary 0.93 and wholemeal bread 1.92 γ B_1 per g. V. Aschehoug

Biochemical indexes of the baking quality of grain and flour. A. I. Oparin. *Bull. acad. sci. U. R. S. S., Sér. biol.* **1939**, 43-67(in English, 67–70).—The baking quality of flour depends not only on its initial chem. compn. but also on the rate at which the chem. processes detd. by the amt. and activity of the enzymes contained in the flour and by the susceptibility of the substances in the flour to fermentative action, take place in the dough during mixing, fermentation and beginning of baking. John Livak

Milling, baking and chemical properties of Colorado-grown Marquis and Kanred wheat stored 9 to 17 years. D. W. Robertson, C. C. Fifield and Lawrence Zeleny. *J. Am. Soc. Agron.* **31**, 851 6(1939). The protein content of Marquis wheat varied from 11.3% in the 1925 harvest to 14.5% in the 1927 crop and from 12.9 to 14.3 in the Kanred wheat. Fat acidity values on Marquis ranged from 26.2 for the 1929 samples to 47.7 for the 1921 samples and on Kanred from 26.7 for the 1929 samples to 37.5 for the 1921 samples. There was a definite and fairly regular increase in fat acidity with storage. All lots of wheat made satisfactory bread. J. R. Adams

The estimation of potato meal in wheat meal. W. Neuwohner. *Z. Tierernahr. Futtermittelk.* **3**, 1–5(1939).—A method similar to that of Klauss (*Vorratspflege u Lebensmittelforsch.* **1**, Nos. 6 and 7(1938)) is described in which a sample dild. with H_2O is treated with K in Kl soln. and an aliquot transferred to a microscopic slide where the amt. of potato starch grains could be estd. by means of their particular intensity of color. J. O. H.

Starch in relation to some baking properties of flour. R. M. Sandstedt, C. E. Jolitz and M. J. Blish. *Cereal Chem.* **16**, 780-92(1939).—Starch and gluten which have been washed from flour can be recombined to form a dough with baking characteristics similar to those of original flour doughs. Various combinations of starch and gluten fractions, and of various treatments can be suitably studied by this technique. The starch from flour can be sepd. into 2 fractions, by centrifuging. One of the fractions is relatively pure starch and the other (smaller fraction) contains dextrins produced by the action of the amylases of the flour on the readily available starch; this fraction is tentatively designated as amylodextrin. The amylodextrin fraction of the flour is a factor in absorption and dets. to a marked extent the handling characteristics of flour doughs. It is closely assocd. with stickiness of doughs and with tenderness of crumb in the baked loaf. The improving effect of malt on many flour doughs is due not to its proteolytic action but to the action of α-amylase on the starch. Certain undesirable baking characteristics of some exceedingly hard wheat starches are due to damage to the starch in milling. Some com. wheat starches seemingly owe their poor baking properties to hypochlorite treatment. The detrimental effect of the hypochlorite may be overcome by treatment with large quantities of malt, the effective agent apparently being the α-amylase component of malt. L. H. Bailey

Changes in flour on storage with special reference to the effect of different types of bags. Wm. H. Cathcart and Edward J. Killen. *Cereal Chem.* **16**, 798–817(1939).—Two different samples of chemically bleached and matched flour were stored separately in 4 different types of bags, viz., ordinary cotton, paper-lined, jute and grain. They were stored under av. com. bakeshop conditions. The samples were analyzed at regular intervals for moisture, ash, protein and absorption, and baking tests were made. The kind of bag had little effect on the analyses or the baking quality of the flour. In all cases absorption increased during storage, ash and protein showed no change, and the baking quality in one sample fell off after the fourth month and in the other after the sixth month. Deterioration in the latter case was due to infestation. The effects incidental to storage are in general agreement with the work of other investigators. L. H. Bailey

The French official method for the determination of fat in flours, pastries and the like. Enid A. M. Bradford. *Analyst* **64**, 817–18(1939).—The French method is described in the *Service de la Répression des Fraudes* but as this is not accessible to many chemists, an English translation of the procedure and description of the app. is given. W. T. H.

Starch as a factor in dough formation. Olof E. Stamberg. *Cereal Chem.* **16**, 769–80(1939).—Upon dilu. of a flour with the various sizes of starch granules, the absorption necessary to produce doughs of a min. mobility of 500 farinograph units at various protein levels was determined. The minima of the resulting absorption curves were at different protein levels when the various starches were used. By calcg. the starch surface area per mg. of protein at these minima the values were 19.8, 20.3, 20.1 and 23.3 sq. cm. for the rice, corn, wheat and potato starch curves, resp., with an av. value of 20.9. Thus the starch surface area was found to be the factor involved at the minima of the absorption curves. It was concluded that for dough formation in the farinograph mixer the protein content of a flour must be over 7.5% (15% moisture) or on a dry basis the ratio of flour protein to starch must be greater than 0.1. Further work is suggested on the possibility of a relationship of flour strength and baking quality to the starch-granule size distribution in flours of various grades and from different sources, since the information now available is incomplete and conflicting. L. H. B.

Gas retention as affected by including shortening in the tentative A. A. C. C. basic test bake formula. W. L. Heald. *Cereal Chem.* **16**, 817–20(1939). It may be concluded that with the app. used and with the patent and straight grade flours, bleached and unbleached, gas retention (as detd. in percentage of total gas retained in the dough) was reduced by the use of shortening. While in the bleached clear flour 2% shortening had a tendency to increase retention, 4% shortening did not materially change the percentage of gas retained over the 2% In all cases of patent straight and clear flours the total rate of gas per hr. was slightly reduced. In the case of patent and straight grades the time to the elastic limit was also reduced. In the clear bleached flour the time to the elastic limit was increased, while in the unbleached it was reduced quite materially. H. believes that the inclusion of shortening in the A. A. C. C. formula would tend to make the baking results more satisfactory on a flour that exhibits bucky characteristics. However, the tendency to mask this bucky effect might render the test bakes less useful. In spite of this fact and knowing that the baker uses a rather liberal amt. of shortening in his formula, H. recommends 3% shortening as being a very desirable amt. to use in the A. A. C. C. baking formula. L. H. Bailey

Standardization of the scoring of test cakes. Olof E. Stamberg. *Cereal Chem.* **16**, 764–8(1939).—Photographs are reproduced showing grain standards and the scoring for symmetry or shape of test cakes, also a table showing the numerical score for cake vols. ranging from 640 cc. to 940 cc. for cakes made from 325 g. batter with the

A. A. C. C. formula. The vol. score is 0 for 640 cc. or less and increases by 1 for every 20-cc. increase in vol. so that a cake having a vol. in the range of 920 and 940 cc. will have a score of 15. L. H. Bailey

Study of checking and pH in cracker and biscuit products. Jan Micka. *Cereal Chem.* **16**, 752–64(1939).—Checking in cracker and biscuit products is assocd. with flour condition and is caused by internal stress and brittleness. The governing factor is pH not only in checking but in the whole process of manufg., i. e., in mixing, machining and baking as well as in the quality of the finished product. A pH on the acid side is responsible for checking and for the unstable condition of the doughs, causing them to become tough with a decrease of elasticity and plastisity. A pH slightly on the alk. side is responsible for the increase of elasticity and plasticity of the dough, causing easier machining with no checking in the finished product. However, if the flour is mistreated in mixing, fermentation and machining, or if there is improper baking (particularly underbaking), cooling, or an unbalanced formula, checking may occur. In soda crackers a blend of soft winter and hard spring wheat flour always causes checking. High absorption and high shortening content have a favorable effect on the stability of the doughs with a tendency to prevent checking. L. H. Bailey

A comparison of methods for the determination of proteolytic activity. F. C. Hildebrand. *Cereal Chem.* **16**, 792–8(1939).—The rate of gelation and viscometric methods of detg. proteolytic activity recently proposed by Landis and Frey (*C. A.* **32**, 3035[8]) and by Koch, Nelson and Ehrnst (*C. A.* **33**, 1872[5]) were investigated in comparison with the Ca pptn. and formol titration procedures; in the last case both gelatin and a flour suspension were used as substrates. This comparison was carried out with a series of samples comprising a reasonably wide variety of cereal products. The gelation-rate and viscometric methods gave results substantially different from those obtained by the other procedures. It may be presumed that the first 2 methods measure proteinase activity, while in the other types of procedure dipeptase and (or) polypeptidase action have the most effect on the results obtained. In these expts. the gelation-rate and viscometric methods had the same expt. error, but the former seems preferable because of its better differentiation between samples. The use of the gelation-rate procedure is limited by its requirement of relatively elaborate and costly app. The modified Ritthausen Cu-pptn. and formol titration methods used were found to give essentially the same relative results. In the formol titration procedure the use of gelatin as a technique leads to lower expt. error and better differentiation between samples. L. H. Bailey

Some factors affecting the stability of certain milk properties. II. Effect of succulent roughages and of storage conditions on color. O. F. Garrett, R. B. Arnold and G. H. Hartman. *J. Dairy Sci.* **22**, 813–20(1939); cf. *C. A.* **33**, 8836[6].—The feeding of properly ensiled grass silage produces a milk higher in total color than does corn silage or beet pulp, corn silage being superior to beet pulp in this respect. There is a small but definite progressive loss of total yellow color of milks in storage. This loss is somewhat accelerated by the pasteurization process and still more by the presence of sol. Cu. The yellow color of high-colored milks is more stable in stored milks and toward catalytic Cu than is that of low-colored milks. The yellow color of milk produced on molasses grass silage is more stable in storage than is that of milk produced on either beet pulp or corn silage. Less loss of color occurs in Guernsey than in Holstein milk during storage. It is suggested that the loss in yellow color in milk is due to deterioration of xanthophyll and zeaxanthin rather than carotene and that these 2 carotenoids exhibit antioxidative protection toward carotene in butterfat. The feeding of molasses grass silage appears to be an excellent means of maintaining a comparatively high level of yellow color in milk during winter months. A. H. Johnson

The determination of chloride in milk. Geo. P. Sanders. *J. Dairy Sci.* **22**, 841–52(1939).—The direct titration of Cl in milk by modifications of Mohr's method, with $AgNO_3$ and K_2CrO_4 indicator yields results which are high and variable. The direct titration method with dichlorofluorescein indicator yields somewhat lower results, but results which are still too high and variable. Indistinct end points with either indicator, and adsorption of Ag by the protein are pointed out as important sources of error. An easy and quantitatively precise modification of the Volhard method is described for detg. Cl in milk. One combined reagent contg. standardized $AgNO_3$, HNO_3 and ferric alum indicator is added to the sample and the percentage of Cl is obtained by titration with standardized KCNS. Sources of error and methods of improvements in other methods as well as conditions necessary for accurate Volhard titrations are described. A. H. Johnson

The phosphatase test. A review of the literature on its application for detecting irregularities in the pasteurization of milk and dairy products. L. H. Burgwald. *J. Dairy Sci.* **22**, 853–72(1939). A. H. Johnson

The determination of milk solids and its application in the dairy industry. L. A. Burgess. *Queensland Agr. J.* **52**, 299–309(1939).—The hydrometer method for detn. of milk solids is described in detail. Methods for detecting adulteration of milk and for detn. of fat losses in buttermilk are discussed. K. D. Jacob

Feed flavors and practical means of controlling them in dairy products. C. E. Wylie and Thomas B. Harrison. *Milk Dealer* **29**, No. 1, 132–4(1939).—The various off-flavors derived from feeds and pastures are described. Onion flavor is the most common feed flavor which gets into milk produced in the southern states. Allyl sulfide is responsible for the onion flavor in the milk. It can be removed by extg. the milk with mineral oil or by aerating the milk. Allyl sulfide being oil-sol. remains with the butterfat on sepn. of the milk. The skim milk contains little if any off-flavor and may be used in the manuf. of cottage cheese. Certain Cl compds. can be used to remove the onion flavor from cream before churning. A. H. Johnson

Similarity of the oxidized flavor from three sources. D. H. Nelson and C. D. Dahle. *Milk Dealer* **29**, No. 1, 62–6(1939).—Pure milk fat free from phospholipides was isolated from fresh sweet cream. This fat was autoxidized in the dark until it had a peroxide value of 25 and then homogenized into skim milk to yield a milk of 4% fat. Such milk dild. with fresh milk of the same fat content had the same oxidized flavor as milk in which the off-flavor was induced by adding Cu to the extent of 2 p. p. m. A. H. Johnson

Proper methods of manufacture and testing of lactic casein. Walter Müller and G. Lichtenberger. *Milchw. Ztg. Alpen-, Sudeten- u. Donauraum* **47**, 105–9(1939).—Detailed directions are given for making casein by the self-sour method and by a method using high-acid whey as precipitant. Directions are given for sampling the pressed curd and detg. total solids and acidity. E. O. Whittier

Production of textile casein from skim milk and the preparation of the residue resulting therefrom (whey). Fr. Richter. *Molkerei-Ztg.* (Hildesheim) **53**, 1163–8(1939).—In the production of textile casein, H_2SO_4 is added to the milk as a pptg. agent. Before the whey can be used in animal feeding it must be neutralized. $CaCO_3$ alone is not a satisfactory neutralizing agent, but the addn. of 100 g. $CaCO_3$ + 100 g. $Ca(OH)_2$ per 100 l. of whey produces a satisfactory feed. E. Curzon

The relation of the refractive index of evaporated and condensed milk serum to the total solid content. S. G. Menefee and O. R. Overman. *J. Dairy Sci.* **22**, 831–40(1939).—Data are presented to show that a linear relationship exists between the total solids and the n of the serum of evapd. and condensed skim milk. The formula developed for one type of product cannot, however, be used to compute quantitatively the total solids in every sample of that product. The variation in compn. of

normal milk and factors such as heat, standardization and acidity that bring about changes in chem. compn. must be considered. The development of acidity in a product is one of the most important problems. Useful refractometer readings can only be made on fresh products.
A. H. Johnson

Feeding of dried whey. H. Bünger, E. Fissmer, W. Harre, H. Schmidt, K. Boehm and F. Reising. *Molkerei-Ztg.* (Hildesheim) **53**, 1447–50(1939); *Biedermanns Zentr.* **11**, 276–300.—Dried whey contains about 90% dry matter, 9% digestible protein and 68% total nutrients. Daily, not more than 0.5–0.6 kg. can be fed to swine and 0.5 kg. to young cattle. E. C.

Change in aroma of butter during storage. W. Mohr, E. Schrimpl and A. Arbes. *Molkerei-Ztg.* (Hildesheim) **53**, 1501–3(1939).—Fresh sweet-cream butter contains little biacetyl (I), the compd. giving butter its characteristic aroma and taste. After storage for 6 months sweet-cream butter contains almost no I. Fresh sour-cream butter contains more I than fresh sweet-cream butter. During storage I may decrease or remain const. Salted and unsalted butter show no differences. Neither storage in CO_2 nor kind of packing material used had any effect on the content of I. Fe and Cu introduced into the butter from the app. increase the content of I during storage and may cause the development of bad flavor.
E. Curzon

Factors affecting amount of mold mycelia in butter. J. Adams and E. H. Parfitt. *Natl. Butter Cheese J.* **30**, No. 10, 29–36(1939); cf. *C. A.* **33**, 7410⁷.—Mold mycelia require O for their growth. In order to reduce mold growth fresh cream should best be added to accumulated cream without mixing as such mixing introduces O into the cream. Molds develop more readily in cream of low fat content than in cream of high fat content. The pH limits (pH 6.0 to pH 8.0) to which cream is neutralized under com. conditions did not influence the amts. of mold mycelia retained in the butter. A. H. Johnson

Quick method for the determination of iron and copper in storage butter. Ritterhoff. *Molkerei-Ztg.* (Hildesheim) **53**, 1478–9(1939).—Butter contg. more than 5 γ iron or 1 γ Cu per g. does not keep well. To det. Fe melt 10 g. butter in an Al beaker and transfer to a white vessel. Add 5 cc. 25% HCl, 5 cc. 10% KCNS and 3 drops of 3% H_2O_2. If the color which develops in the watery layer is yellow or only faintly red less than 5 γ Fe/g. is present; if it is bright red more than 5 γ is present. To det. Cu melt 10 g. butter and boil gently to destroy the catalase. Avoid browning the fat. Add 5 cc. of 10% KCNS and 10 drops of fresh Schrödter's guaiacum reagent. The color may range from colorless through green to blue. The first trace of blue color indicates a Cu content of more than 1 γ/g. E. Curzon

Suggestions on making process cheese. C. R. Barker. *Natl. Butter Cheese J.* **30**, No. 10, 24–6(1939).—An important asset in maintaining the uniformity of process cheese is the control of acidity. This is best controlled by judicious use of acid cheese in the blend. Such emulsifiers as are necessary should be used sparingly.
A. H. Johnson

Factors affecting activity and heat resistance of Swiss cheese starter cultures. II. Influence of culture medium. P. R. Elliker and W. C. Frazier. *J. Dairy Sci.* **22**, 821–30(1939); cf. *Ibid.* **21**, 801–13.—*L. helveticus*, *L. lactis* and *Lactobacillus* sp. all developed more actively in freshly prepd. than in old sterile reconstituted milk. The age of the sterile reconstituted milk used as a culture medium had no significant influence on growth of *Str thermophilis*, *Str. lactis* and *E. coli*. Substances such as peptone, tomato juice, yeast water and lactic filtrate stimulated growth of *L. helveticus* in both old and freshly prepd. sterile reconstituted milk. The oxidation-reduction potential of steamed, freshly prepd., sterile reconstituted skim milk was significantly lower than that of steamed old sterile reconstituted milk. Addn. of a reducing substance, neutralized thioglycolic acid, to old sterile reconstituted skim milk stimulated development of certain lactobacilli but did not significantly stimulate development of *Str. lactis*, *Str. thermophilis* and *E. coli*.
A. H. Johnson

Cheese swelling. Hans Roeder. *Molkerei-Ztg.* (Hildesheim) **53**, 955–7(1939).—Addns. of chicken egg white, peptones and heavy metals may affect the rennet coagulation of milk; urea inhibits it markedly. Urea added to milk samples not contg. rennet does not coagulate the milk in spite of the great increase in acidity. Heating the milk + urea or the urea soln. before adding it to the milk does not affect the swelling. Hence changes due to bacterial action, but not affected by pasteurization may make milk unsatisfactory for cheese making. E. C.

The continuous production of margarine. Lars Erlandsen. *Fette u. Seifen* **46**, 536–40(1939).—Modern methods for producing margarine are reviewed and the advantages of the continuous process are pointed out.
J. W. Perry

Egg solids. M. A. Widland and M. J. Mack. *Ice Cream Trade J.* **35**, No. 10, 21, 48, 56 (1939).—Ice cream contg. egg solids has improved whipping properties, is more firm when drawn from the freezer, withstands heat shock well, and has a smooth compact appearance, relatively free from visible air cells. The egg powder blends appear to be of value to the extent that they contain egg-yolk solids. These blends appear to contain egg-yolk solids along with milk-solids-not-fat and albumin or whole egg solids. A modified Mojonnier procedure was described for the detn. of fat in egg-yolk products. The protein content of egg yolk or egg powder blends can be detd. by the Kjeldahl method. By detg. protein and fat a satisfactory appraisal of an egg-yolk product can be made. The detn. of the egg-yolk solids of a product is difficult and usually gives results that are lower than the actual amt. of egg-yolk solids actually present.
A. H. Johnson

A practical method of determining color in fresh and frozen egg yolks. A. W. Turner and V. Conquest. *U. S. Egg Poultry Mag.* **45**, 668–70(1939).—Color comparison is made between an acetone ext. of the yolks with standard $K_2Cr_2O_7$ solns. H. A. Lepper

The composition of local and imported citrus fruit. A. W. R. Joachim and D. G. Panditteseker. *Trop. Agr.* (Ceylon) **93**, 14–24(1939).—The detn. of total solids, acidity, sugars, vitamin C and pH in 62 samples of local and imported grapefruit and oranges showed that Ceylon citrus fruits are similar in compn. to citrus from other countries. Ceylon fruits were inferior in such characteristics as color, thickness of rind, facility of peeling, character of rag and seedlessness. John O. Hardesty

Boron status of New Zealand apples. H. O. Askew and R. H. K. Thomson. *New Zealand J. Sci. Tech.* **21A**, 128–9(1939).—Apples from Auckland, Hawke's Bay, Marlborough, Canterbury and Central Otago districts were analyzed for B. All except those from the last district showed a satisfactory B status. The fruit from all districts was free from internal cork. J. O. H.

Removal of nicotine-bentonite spray residues from apples at harvest. Jack E. Fahey, Harold W. Rusk, L. F. Steiner and R. F. Sazama. *Trans. Indiana Hort Soc.* **78**, 114–15(1938)(Pub. 1939).—One lot of fruit, which had received 7 sprays of a mixt. of 40% nicotine sulfate 1 pint, bentonite 5 lb., soybean oil 1 quart and Na lauryl sulfate 0.5 oz./100 gal. and which carried a harvest residue load of 0.026 grain nicotine per lb., was washed in a machine of the underbrush type with 5 different solns. A 5% Na silicate wash at 60–100°F. reduced the nicotine residue to less than 0.001 grain per lb. and completely removed the visible residue. Washes contg. 0.25% of wetting agent alone or in combination with 1.1% HCl reduced the residue to 0.004–0.006 grain per lb. but left appreciable visible residue on the fruit.
K. D. Jacob

Warehouse ventilation and gas storage [of apples and pears]. C. A. Eaves. *Ann. Rept. Nova Scotia Fruit Growers' Assoc.* **74**, 48–51(1937).—When the Cox Orange and Ribston varieties of apples were subjected to an atm. of 100% N_2 for 4 days before storage there was a marked retardation in the yellowing of the ground color and the

fruit was much firmer than comparable lots that had been stored in air from the time of picking. The treatment also prevented Ribston apples from becoming greasy. Equally good results were obtained by treating McIntosh apples with pure CO_2 for 3 days or with pure N_2 for 4 days. Treatment of Russet apples for more than 8 days with either CO_2 or N_2 seemed to be necessary to prevent shrinkage. Clapp Favorite and Bartlett pears were benefited by treatment with N_2 but CO_2 was ineffective. Prolonged holding of McIntosh apples in 5% CO_2 under cellar conditions resulted in very good keep and the elimination of a corticle browning that appears in this variety under ordinary conditions. Russet apples also responded to this treatment but it was ineffective with the Cox Orange and Ribston varieties. K. D. Jacob

The effect of recent increase in government lead tolerance on spray practice. C. L. Burkholder. *Trans. Indiana Hort. Soc.* **78**, 85(1938)(Pub. 1939).—The increase in Pb tolerance from 0.018 to 0.025 grain per lb. of fruit, with no change in the As tolerance of 0.01 grain per lb., has given growers only a slight increase in margin of residue safety but no grounds on which to base hopes that more or heavier sprays can be applied without washing or that there can be any let-up in washing efficiency, especially if the fruit is to go into interstate shipment. K. D. Jacob

Observations with reference to arsenic [and lead] on apples and other foodstuffs. Ira D. Cardiff. *Proc. Wash. State Hort. Assoc.* **33**, 153–68(1937).—A review and discussion of the occurrence of As and Pb in foodstuffs, beverages, plants, etc., the effects of As and Pb on the animal organism, discrepancies and errors in the detn. of these elements in food products, and the activities of the Food and Drug Administration in enforcing the regulations concerning tolerances for Pb and As in food products, particularly apples. K. D. Jacob

The composition of the fruits of Mespilus germanica. R. Sartory, E. Weil and S. Aziz. *Bull. acad. méd.* **121**, 885–6(1939).—The fresh fruit contains 2.59% of tannin which justifies its use in dysentery. A table of compn. is given. A. E. Meyer

Vitamin C in fruit-juice products. I. Influences of the process of preparing canned tomato juice on the vitamin C content. Tyoten Inagaki. *J. Agr. Chem. Soc. Japan* **15**, 903–14; *Bull. Agr. Chem. Soc. Japan* **15**, 136(in German)(1939).—Ascorbic acid-oxidizing enzyme was found in canned tomato juice. Its action was completely checked by heating at 65° for 10 min. The vitamin C content was 21.5 mg. % in the fresh tomato pulp and 27.9 mg. % in the peel or the seeds. When the tomato juice was sealed in a can with varnish lining, there was a large decrease in vitamin C and all of it was lost during storage for 6 months. Sterilization by heating for a short time was recommended from the viewpoint of the vitamin C content. Y. Kihara

Maturity studies of soft fruits. J. E. Britton. *Proc. Wash. State Hort. Assoc.* **33**, 55–8(1937).—Bing, Lambert and Victor cherries, picked at max. wt., contained 21.3, 17.0 and 17.5% sugar, resp. More mature fruit showed a further increase in sugar but a slight decrease in wt., shorter storage life and a tendency to shrink and lose brightness. Fruit contg. under 16% sugar shriveled in storage, had a poor flavor and soon became unattractive in appearance. Peach plums contg. 12.5% sugar had the best keeping qualities. Sugar content was not a reliable maturity test for peaches. A sugar content of 17% for the Italian prune appeared to be a safe guide to quality when picking. In all cases, the sugar content was detd. by means of the Zeiss refractometer. K. D. Jacob

The drained weight of English canned fruits. F. Hirst and W. B. Adam. *Univ. Bristol, Fruit Vegetable Preservation Research Sta., Campden, Ann. Rept.* **1938**, 17–31.—Shrinkage and shriveling were seldom very noticeable unless sirups of 55–65° Brix were used, but cherries were affected at densities as low as 40–45° Brix. The temp. at which the sirup was allowed to enter the can had little or no effect on the subsequent drained wt. 1 The decreases in drained wts. that occurred during the 1st 1–2 weeks of storage tended to be overcome with further storage. K. D. Jacob

The vitamin C content of edible Argentine vegetables. Osvaldo M. Repetto. *Anales asoc. quím. argentina* **27**, 140–4(1939).—See *C. A.* **33**, 7905[9]. E. M. Symmes

The composition and texture of dried peas. III. W. B. Adam. *Univ. Bristol, Fruit Vegetable Preservation* 2 *Research Sta., Campden, Ann. Rept.* **1938**, 60–7; cf. *C. A.* **33**, 2641[8].—Artificial drying of shelled mature peas for 6–7 hrs. at 120–160°F. appeared to toughen the texture very slightly. The time required for the ashing of dried peas in a muffle furnace to complete disappearance of the C was 24, 18, 8 and 2 hrs. at 500, 630, 750 and 900°C., resp. Peas ashed at 500° and at 900°, resp., contained 2.86 and 2.68% ash. The percentages of CaO, MgO and P_2O_5 in the ash increased and those of K_2O decreased 3 with increase in the temp. of ashing. The P content of peas, obtained by wet digestion, was 7% higher than that obtained by ashing. K. D. Jacob

Vitamin C in potatoes at Batavia. J. H. de Haas and O. Meulemans. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 181–4(1939).—Potatoes grown in Batavia had an av. vitamin C content of 13–15 mg.% when raw and 8–9 mg. % when boiled. E. Curzon

Polish honey from the chemical point of view. Jadwiga Podgórska. *Arch. Chem. Farm.* **4**, 23–36(in German, 4 36)(1939).—P. performed complete analyses of about 50 samples of domestic honey. The results of these analyses are given in 4 tables. In Polish honey of good quality the so-called ratio no. of Auerbach and Bodländer (L = (levulose/glucose) × 100) amounts to 88–116. 12 references. Edward A. Ackermann

The hygroscopic properties of honey. E. C. Martin. 5 *J. Econ. Entomol.* **32**, 660–3(1939).—Honey exposed to air establishes an equil. in water content with the air moisture. The uptake of water is at first rapid and then proceeds more slowly as equil. is reached. The exchange of water between honey and air is a surface phenomenon; but the change in water content occurs throughout the honey by diffusion. Through the formation of a surface film, the change in moisture content of honey in dry atms. is retarded. The optimum relative humidity for drying honey is not 0; and while not detd. exactly it lies 6 between 0 and 20%. Cryst. honey changes water content more rapidly than liquid honey. When cryst. honey is exposed to a moist atm. a steady liquefaction of the dextrose crystals takes place. Liquid honey contg. 17.4% H_2O is in equil. with the water vapor in air of 58% relative humidity; cryst. honey attains equil. at a slightly higher relative humidity. Honey is best stored at relative 7 humidities of not over 60%. Moisture exchange occurs through the capping of honey in the comb. The hygroscopic qualities of honey are due chiefly to the presence of levulose; but the other ingredients play some part. C. H. Richardson

Time and temperature in relation to the destruction of sugar-tolerant yeasts in honey. G. F. Townsend. *J. Econ. Entomol.* **32**, 650–4(1939).—The vegetation stages of *Zygosaccharomyces mellis, Z. nussbaumeri, Z. richteri, Z. nectarophilus* and *Torula mellis*, which are a common 8 cause of fermentation in Canadian honeys, are destroyed in honey contg. 18.6% moisture by heating 3 min., 35 sec. at 68.3° and by heating 180 min. at 54.4°. Intermediate times and temps. are shown in a graph. C. H. R.

The sugar concentrations of western nectars. Geo. H. Vansell. *J. Econ. Entomol.* **32**, 666–8(1939).—Nectars taken by pipet from various flowers, or from the honey 9 sacks of honeybees after they had visited the blossoms, were examd. by a refractometer for sugar content. Nectars from 8 varieties of plums showed from a trace to 28.4% sugar; nectar from 6 varieties of vetch 22.6–56.5%. Red filaree, black locust and several species of willows gave the highest values (60–65%), while several varieties of apricots, *Cleome lutea*, and madrone gave the lowest (10–12%). The av. sugar concns. in nectars from 76 plants in Western U. S. A. are tabulated. The data

represent an index of the theoretical honey value of the plants. C. H. Richardson

Analysis of ground pimento. Mme. Dumas. *Ann. fals.* **32**, 247-50(1939).—Analysis of 9 samples of the ground dried fruit of *Capsicum annuum* gave the following results: H_2O 6.79–13.07, nonvolatile oil 9.35–12.80, volatile oil 0.16–0.39, ash 5.80–6.99, carbohydrates (reducing matter in water-sol. ext.) 8.70–14.40, proteins (N × 6.25) 14.88–16.65, crude fiber 20.65–24.50%. The ash had the following compn.: H_2O-sol. 80.05–83.75, H_2O-insol. 16.25–19.95, alky. of ash (as K_2CO_3) 57.65–66.80, SO_3 2.95–3.48, P_2O_5 15.80–16.83, SiO_2 4.11–5.60, Fe_2O_3 + Al_2O_3 17.92–20.94, CaO 4.68–6.07, MgO 7.65–8.82, K_2O 33.28–35.87% and Mn trace. The nonvolatile oil was a deep-red, viscous liquid, with sharp taste, exhibiting no fluorescence under filtered ultraviolet light, possessing considerable drying properties, and having the following characteristics: n_{20} 1.4812–1.4836, I value 131.9–141.6, acid value 15.85–25.95, sapon. value 184–195 and ester value 164.40–173.25. A. P.-C.

Cacao powder: quality depends on important processes. K. E. Langwill. *Mfg. Confectioner* **19**, No. 10, 18–19 (1939).—The effects of various steps in processing cacao powder upon the quality of the product are discussed. George Ayers

Biochemical control of tea manufacture. A. L. Kursanov. *Bull. acad. sci. U. R. S. S., Sér. biol.* **1939**, 71–84(in English, 84).—Several easily detd. chem. and phys. values are proposed as indexes for the guidance of the processes involved in tea manuf. In particular, it is shown that the end of dry-curing can be detd. by the amt. of residual water, rolling by the percentage of crushed tissue, and fermentation by the decrease in sol. tannin. The optimum limits are 60–1% residual water, 77–85% crushed tissue, and 12–16% tannin. Tea processed in this manner is of higher quality than tea processed by the usual methods of production control. John Livak

Report of the biochemical department for 1938. [Tea manufacture.] Roland V. Norris. *Tea Research Inst., Ceylon, Bull.* No. **19**, 65–75.—Exts. prepd. from tea manufd. by the Clivemeare process contained slightly less caffeine, theotannin and sol. material than did those manufd. by the customary process. The better and stronger color of the Clivemeare ext. appeared to be due to some change in the character of the sol. materials and not to their total amt. As compared to that obtained by the customary process, the leaf leaving the Clivemeare roller had a higher enzymic activity and fermented more rapidly. K. D. Jacob

From which fodder plants and at what cutting times, is the greatest quantity of digestible protein harvested under the continental climatic conditions of central Germany? Alfred Gertler. *Kühn-Arch.* **48**, 56–124 (1939).—The protein contents and starch values of 9 legumes and several mixed grasses were detd. for various field and harvesting conditions. Plots which were mowed 5 times beginning in April yielded 12–55% more protein than those cut later and less often. The ratio of protein: starch value increased from 1.5.2 for the former to 1·14.2 for the latter. The drying of hay resulted in a loss from the green material of about 50% protein and 19% starch. Hay which was cut late (after the end of May) decreased 60% and 21% in protein and starch, resp. The red lupine was the best protein producer (2763 kg./ha.). The starch values of the different legumes did not parallel their protein contents. The max. protein formation in sweet vetch and soybean required 14–30 days longer than for max. starch production; their rates of formation in the grasses were more nearly parallel. Fifty-four references. C. K. Horner

The digestibility of fresh lucern, lucern hay, lucern meal and fermented lucern with sheep. K. Scharrer and R. Schreiber. *Z. Tierernähr. Futtermittelk.* **3**, 27–44 (1939).—The digestibility of dry matter, org. matter, crude protein and N-free ext. did not vary greatly in the hay, meal or fresh lucern, but was somewhat less for all of the constituents except crude protein in lucern silage which had been acidulated with either org. or inorg. acids. The digestibility coeff. for fat in the hay was 43.38 and in the meal, 48.13%. The digestibility coeff. for crude fiber was highest (52.42%) in the fresh lucern. The fat in the silage was more digestible than that in the untreated lucern. Acidulation of the silage with org. acids produced better digestibility of crude fiber than that with inorg. acids. The digestible protein content was high in both the hay and the meal but the starch value was higher in the meal. High values for starch and digestible protein were obtained with silage which was acidulated with either org. or inorg. acids. J. O. H.

The formic acid content of samples of fermented feeds and the error caused by formic acid in the determination of acetic, butyric and lactic acids. Oscar Flieg. *Z. Tierernähr. Futtermittelk.* **3**, 53–66(1939).—In the usual methods of detg. acetic, butyric and lactic acids in fermented feeds some HCO_2H is carried over into the distillate and influences the results of analyses. The HCO_2H content ranged from 0 to 0.09, with an av. of 0.032%, in 42 different samples of silage prepd. in various ways with addn. agents such as sugar and mineral acids. The HCO_2H content ranged from 0.011 to 0.348, with an av. of 0.172%, in 75 different samples which had been fermented in the presence of *Amasil*, a prepn. contg. 1 part of 90% HCO_2H in 20 parts H_2O. No relation was established between the HCO_2H content of the fermented feed on the one hand and the amt. of *Amasil* supplied, the kind of feed used, H_2O content of the green material, season of the year or duration of fermenting period on the other. The errors due to the presence of HCO_2H in feeds free from *Amasil* were negligible. With fermented fodder contg. *Amasil* the max. errors for acetic, butyric and lactic acids were, resp., +0.404, −0.078 and −0.204%. To avoid the direct detn. 3 equations for evaluating the HCO_2H content are proposed which operate in connection with the analytical procedure for the detns. of acetic and butyric acids. From the data obtained corrections can be made for the av. errors in the analytical results for acetic, butyric and lactic acids. Spoiled samples can be detected because of their low contents of HCO_2H. Applying the corrections to analytical data obtained on fermented feeds treated with *Amasil* gave reliable results in a large majority of cases. John O. Hardesty

The use of cull apples as feed for dairy cows. J. C. Knott. *Proc. Wash. State Hort. Assoc.* **33**, 43–6(1937).—Silage made from a mixt. of chopped apples 80 and chopped alfalfa hay 20% averaged 23.8% dry matter which contained crude protein 9.4, crude fiber 29.1, ether ext. 3.2, N-free ext. 51.2 and ash 7.1%. In a 2-yr. expt. on dairy cows, the digestibilities of the constituents of the silage were: dry matter 58, protein 51, fiber 49, ether ext. 47 and N-free ext. 70%. *Effect of Pb arsenate on cows.* Cows that were fed 30 lb. apples and 0.75–1.5 g. Pb arsenate (equiv. to 0.23–0.46 grain Pb and 0.083–0.166 grain As per lb. of fruit) per day for 2 months showed no ill effects except that they seemed to be more subject to digestive disturbances. Most of the As was excreted in the urine and little or none in the milk. Only traces were found in the blood. K. D. Jacob

Further studies on the nature of the effective supplements for soybean-oil meal in chick rations. J. B. Christiansen, H. J. Deobald, J. G. Halpin and E. B. Hart. *Poultry Sci.* **18**, 481–5(1939).—Flavin and possibly other vitamins appear to be factors supplied in inadequate amts. by soybean-oil meal. K. D. Jacob

---

Detn. of fats in fatty products used in baking (Schmalfuss) **27**. Fractionation of the $CHCl_3$ ext. of maple sirup (Sair, Snell) **28**. [Report of] molasses lab. (Lamb) **16**. Recent developments in stored foods (Page, Lubatti) **1C**. App. for taking samples of milk and means for transporting the app. in a sterile condition (Brit. pat. 508,585) **1**.

Bleaching powder-dispensing device for flour mills. Paul E. Sage. U. S. 2,174,138, Sept. 26. Various structural, mech. and operative details.

Homogenizing apparatus for treating milk, etc. Wilfred

K. Krauss. U. S. 2,172,661, Sept. 12. Various structural, mech. and operative details.

Drying whey by the drum process. Geo. C. Supplee (to Borden Co.). U. S. 2,173,922, Sept. 26. There is added to whey an org., nongel-forming, nongelatinized, water-insol., antimelassigenic substance adapted to give porosity to the drying film, such as a diatomaceous earth, and the mixt. is desiccated by heating it to above about 93° on a drying cylinder.

Coating cheese to prevent mold growth. Ronald Wood. U. S. 2,172,781, Sept. 12. To prevent mold growth and loss of moisture and fat, the outer surface of cheese is softened by immersing it in an alk. soln. such as one of Na_2CO_3 at a temp. of about 88° until a portion of the cheese surface has been converted to an alkali caseinate coating of such thickness that when dry it is capable of preventing fat from sweating out through it, followed by drying the surface to harden the coating.

Fermentation process for improving odor, taste, stability and consistency of margarine or the like. Willy Ekhard. U. S. 2,172,531, Sept. 12. A process for improving margarine comprises treating the fat prior to churning with microörganisms of the class consisting of bacteria which produce an org. acid, and yeasts, in the presence of a carbohydrate which can be fermented by means of the microörganisms, and then treating the fat so as substantially to sep. the foreign fermentation products, the foreign fermentation products substantially being alc. and lactic acid formed by the action of the microörganisms. Details are given of the treatment of whale oil, peanut oil, soybean oil and tallow.

Preserving eggs. S. A. C. S. A. (Società anonima conservazione sterilizzazione alimentari). Brit. 507,524, June 16, 1939. See Fr. 838,999 (*C. A.* **33**, 6983[4]).

Use of salts and ultraviolet rays in curing meats. Hugh E. Allen (50% to Albert G. McCaleb). U. S. 2,173,992, Sept. 26. Curing salts such as a mixt. of NaCl with a minor proportion of $NaNO_2$, $NaNO_3$ and mono-Na glutamate, etc. (suitably in aq. soln.) are treated with rays such as those from a Hg-vapor quartz lamp before use in curing meats, which enables the curing process to be satisfactorily carried out at higher temps. (up to about 24°) than without the use of such actinic rays. Numerous examples are given.

Preservative tissue paper for wrapping citrus fruits. Robert G. Mispley and Wm. R. Barber (to Crown Zellerbach Corp.). U. S. 2,173,453, Sept. 19. A preservative tissue paper fruit wrapper contains about 0.0175 to 0.0297 of its wt. of biphenyl bonded to the sheet by a solvent carrying the biphenyl and consisting of liquid paraffin oil fortified with paraffin wax, the biphenyl-carrying solvent approximating between 7% and 9% of the wt. of the paper, the wrapper having resistance to disintegration by contact with moisture and capacity to prevent the dissipation and thus the loss in effect of the biphenyl by volatilization for a relatively long period of time, the wrapper permitting respiration of the fruit wrapped in it yet controlling evapn. of the fruit through its pores.

Apparatus for extracting juice from grapes without crushing the stems or seeds. Abele Ferrari, Mario Scalione and Cesare Rafanelli. U. S. 2,172,790, Sept. 12. Various details of an app. having an apertured drum and spiral beating blades mounted on a shaft within the drum.

Controlling the jelling properties of extracted pectins. Herbert T. Leo, Clarence C. Taylor and John W. Lindsey (to Mutual Citrus Products Co.). U. S. 2,173,260, Sept. 19. A method of controlling the temp. of set of pectin at a specified pH value comprises subjecting pectin to the action of an aq. acid soln. of a pH of about 1.25 at a temp. between about 60° and 77°, removing and testing a sample of the resulting soln. to det. the temp. of set of the pectin content at the specified pH value of such sample at the time of its removal, and, when the test indicates a satisfactory temp. of set at the specified pH value, interrupting the action of the aq. acid soln. by diln. with cold water and the addition of a buffer salt numerically to increase the pH of the soln. above about 2.7 to recover pectin having the desired temp. of set at the specified pH value, the temp. of set of the recovered pectin being equiv. to a temp. of set of about 103° at a pH of 2.30.

Food production from oleaginous seeds such as soybeans. Martin Cohn. U. S. 2,172,699, Sept. 12. App. is described, and a process which comprises swelling raw seeds in whole condition by soaking with water, pressing the raw, whole seeds into extremely thin skin-like films by forcing them under pressure through a very narrow gap between heated, revolving surfaces and retaining the films in contact with one of the heated surfaces until dry.

Cooking salt. Chematex Ltd. Brit. 507,904, June 19, 1939. In cooking, i. e., boiling, steaming, baking, grilling and frying, meat, vegetables, cereals and other foods normally cooked with NaCl, a prepn. is used that consists substantially of NaCl and contains 4–10% of Na or (and) K orthophosphate, the prepn. being in soln. alk. to methyl orange. The prepn. is applied directly to the foodstuff or dissolved in its cooking liquor. Sol. sulfates and (or) bicarbonates, e. g., 1-25% Na_2SO_4 or 1-10% $NaHCO_3$, may be included. Cf. *C. A.* **32**, 4291[4].

Gum confections. Arthur D. Fuller (to National Adhesives Corp.). U. S. 2,173,878, Sept. 26. Sugars are used with a chlorinated reaction product, formed from a starch and an alkali hypochlorite contg. excess alkali; it gives to the confection longer shelf life, greater jelling characteristic, increased transparency, and quicker drying characteristic than are possessed by gum confections employing thin or thick cooking starches.

13—CHEMICAL INDUSTRY AND MISCELLANEOUS INDUSTRIAL PRODUCTS

(PLASTICS, RESINOIDS, INSULATORS, ADHESIVES, ETC.)

HERMAN A. BRUSON

Vocational guidance in chemistry and chemical engineering. Anon. *Ind. Eng. Chem., News Ed.* **17**, 701-6(1939). —Report of a committee of the Am. Chem. Soc. There is an extensive bibliography. E. J. C.

New chemical engineering building at Case School of Applied Science. E. A. Arnold and D. O. Hubbard. *Ind. Eng. Chem., Anal. Ed.* **11**, 675–7(1939). G. G.

Why we are storing manganese. W. T. Cobb. *Barron's* **19**, No. 46, 20 (Nov. 13, 1939).—Most of our supply comes from distant countries. Improvements in processes may make U. S. low-grade deposits more important.
A. M. Patterson

Tests available for the identification of small quantities of the war gases. H. E. Cox. *Analyst* **64**, 807–13(1939). —Notes are given for the detection of the following by known reactions: Cl, $COCl_2$, $COCl.OCCl_3$, $ClCOOCH_3$, $GCl_3.NO_2$, $C_6H_5.CH_2Br$, CH_3COCH_2Br, $CH_2Br.CO_2C_2H_5$, $CH_2I.CO_2C_2H_5$, $C_6H_5CHBr.CN$, $C_6H_5COCH_2Cl$, $[C_6H_5]_2$-AsCl, $[C_6H_4]_2NH.AsCl$, $[C_6H_5]AsCN$, $[C_6H_4]_2NH.AsCN$, $[CH_2CH_2Cl]_2S$, CHCl $CHAsCl_2$, $C_2H_5AsCl_2$, CH_3AsCl_2, $C_6H_5NCCl_2$, CH_3SO_3Cl and $C_2H_5SO_3Cl$. The question whether food that has been exposed to war gas is poisonous when taken internally will usually resolve itself into the detn. of the cyanide or As content. For the purpose of assessing the harmfulness it will be well to evaluate the poisonous properties in terms of HCN or As_2O_3. W. T. H.

Detection methods of war materials proposed in literature. Geo. Dultz. *Wien. Pharm. Wochschr.* **72**, 548–52 (1939).—A review dealing with β,β'-dichloroethyl sulfide, war chemicals contg. As (aliphatic and aromatic), $COCl_2$, Perstoff and chloropicrin. 20 references.
H. M. Burlage

Antidotal rocks and silicosis. F. Bremner. *Can. Mining J.* 60, 589–95(1939).—Many aluminous rock dusts are capable of reducing the soly. of quartz to a marked degree when mixed together in equal proportions. Dialyzable Al_2O_3 can be readily leached from many aluminous rocks and mineral dusts under conditions quite comparable with those existing in body fluids. This dialyzable Al_2O_3 is capable of forming stainless aluminous coatings on fractured quartz surfaces. The formation of this coating is the most important factor in reducing the true rate of soln. of quartz particles. The modifying effect of these dusts on the action of free SiO_2 in the lung is believed to be chiefly due to their coating ability. These aluminous dusts are not recommended as protector dusts when a more concd. and active form such as metallic Al is available. W. H. Boynton

Identification of hydrated alumina films of importance in silicosis prevention. L. H. Germer and K. H. Storks. *Ind. Eng. Chem., Anal. Ed.* 11, 583–92(1939).—Electron-diffraction diagrams are employed for the detection and identification of thin protective films of hydrous alumina on silica, as encountered in studies of the prevention of silicosis (cf. *C. A.* 31, 6369[8]; 33, 3019[8]). Films of silica about 200 A. thick were prepd. by vaporization onto thin condensed films of gold on glass, the gold being dissolved off as needed. Fragments of these films were then floated upon the surface of water in which aluminum powder was immersed and maintained for 1 or more days at 38°. Films so treated, and supported when necessary on an auxiliary film of "Formvar," yielded electron-diffraction diagrams of α-AlOOH, or *boehmite*. Substitution of $Al(OH)_3$ for Al in the treatment yielded much thinner films, but of the same compn. Silica or Formvar films alone gave amorphous ring patterns. In each case the α-AlOOH was more or less perfectly oriented with normals to a 6.2 A. spacing normal also to the films. Scums which formed on the water surface during prepn. of samples were identified in some cases (with paraffined beakers) as Al soaps or mixts. of Al soaps with α-AlOOH, and in others (with Bakelite beakers) as α-AlOOH. Attention is called to the fact that the hydrous alumina films are probably altered to α-AlOOH by the drying process preceding diffraction registration, not deposited as such. W. F. Bradley

Determination of the particle sizes of dusts. A. Winkel. *Chem. App.* 26, 265–9, 281–3(1939).—A review of methods of particle-size detn. with special reference to the application to chem. industries. 30 references. G. W. S.

The shattering of dust particles by the impinger. D. G. Beadle. *J. Ind. Hyg. Toxicol.* 21, 109–20(1939).—Large dust particles are shattered by the impinger method, thereby producing high dust counts. A. L. Elder

Further observations on the possible systemic toxicity of certain of the chlorinated hydrocarbons with suggestions for permissible concentrations in the air of workrooms. Cecil K. Drinker. *J. Ind. Hyg. Toxicol.* 21, 155–9(1939); cf. *C. A.* 31, 8681[8].—A high-Ca diet has no protective effect against liver lesions. Administration of xanthine does not prevent liver injury. High urinary chlorides follow the feeding of hexachloronaphthalene to dogs. The permissible limits of these compds. in air of workrooms is 0.5–10.0 mg./cu. m. A. L. Elder

Decomposition of halogenated hydrocarbon vapors by smoking. Hervey B. Elkins and Leo Levine. *J. Ind. Hyg. Toxicol.* 21, 221–5(1939).—Smoking cigarets, cigars and a pipe in air contg. 500–1000 p. p. m. of halogenated hydrocarbons yield little halide and on the basis of decompn. of compds. does not constitute a health hazard. A. L. Elder

Fatal subacute occupational lead poisoning. W. Ehrhardt. *Arch. Gewerbepath. Gewerbehyg.* 9, 407–13(1939).—A man working with Pb sprays suffered colic, vomiting, diarrhea, salivation, weakness of muscles and transitory paresis of the legs. Necropsy showed kidney and liver damage. Pb content of the blood was 185 γ %, that of the kidneys 370 γ in 10 g. of dry substance. M. M. R.

The urinary sulfate test in the supervision of workers exposed to benzene. C. M. Jephcott and F. M. R. Bulmer. *J. Ind. Hyg. Toxicol.* 21, 132–40(1939).—Data on 68 workers exposed to C_6H_6 indicate that the urinary sulfate test has some value in estg. the relative degree of exposure to C_6H_6 but is not a measure of the effect of C_6H_6 on the worker. A. L. Elder

The plastics industry. V. E. Yarsley and E. G. Couzens. *Mem. Proc. Manchester Lit. & Phil. Soc.* 83, 161–74 (1938–39); cf. *C. A.* 33, 4343[4]. E. H.

The measurement of the technical pressing properties of hardenable synthetic resin plastic materials. M. Krahl. *Kunststoff-Tech. u. Kunststoff-Anwend.* 9, 339–42(1939).—A review of testing methods with eight references. T. E. R. Singer.

How can a control laboratory check 100% phenolic resins accurately? J. B. Heymes. *Am. Paint J.* 24, 45–8(Dec. 4, 1939).—A table groups these resins: (1) those neither heat-reactive nor oil-reactive, (2) those that are oil-reactive, (3) those that are heat advancing or resin hardening and (4) dark low-cost or cresol resins. Characteristics are tabulated of 3 resins of each group. Improved control tests and uniform methods of testing should be established. W. H. Boynton

Analysis of synthetic resins containing maleic acid. Erik Sadolin. *Ind. Eng. Chem., Anal. Ed.* 11, 608–10 (1939).—Alkyd resins made with maleic acid and rosin (0.2-g. sample) were dissolved in 5 cc. benzene and refluxed 1 hr. with 20 cc. *N* KOH in 90% EtOH. After evapn. of EtOH and benzene, free rosin was pptd. by acidifying to Methyl Red. The rosin-maleic acid addn. product (I) remaining in soln. was pptd. by $Pb(OAc)_2$ as a mixt. of 33% $(C_{24}H_{31}O_6)_2Pb_3$ and 67% $(C_{24}H_{32}O_6)Pb$. Rosin alone and PhOH-CH_2O resins give no Pb ppts. in this procedure, while phthalate resins give a cryst. ppt. of $C_6H_4(COOH)COOK$ after the acidification step. The amt. of I decreases from 100 to 60% of the theory during resin prepn. at 260°. Arnold M. Collins

Polymeric resins in surface coatings. Arthur K. Doolittle. *Drugs, Oils & Paints* 54, 382–4(1939).—The most obvious difference between cross-linked or 3-dimensional structure and linear structure is that the former gives in general infusible resins and the latter thermoplastic resins. Where the growth of the large mols. involves ester linkages the chem. and water resistance of the coating is much less than where the growth takes place by satd. C-C linkages as in the polymerization of vinyl compds. Similarities and differences of several of the polymeric type resins are pointed out. The structural formulas of rubber chloride, copolymer vinyl chloride-acetate, depolymerized and cyclized rubber and polyacrylates and methacrylates with emphasis on the properties of vinyl resins are indicated. W. H. Boynton

Heat insulation. E. A. Allcut. *J. Can. Ceram. Soc.* 8, 4–9(1939).—The best insulators are those that combine high resistance to passage of heat, durability, resistance to fire, moisture and vermin. The "K" factor or cond. is defined as the quantity of heat that will pass through 1 sq. ft. of material in 1 hr. if the thickness is 1 in. and the temp. difference between the 2 surfaces is 1°. The reflection of radiant heat from bright metallic surfaces such as Al and Cu is frequently used for insulating purposes. Crumpled foil is also used to break up air spaces into small cells. Metallic paints are used on fiber, gypsum and other insulating boards but the effectiveness of such methods may be greatly reduced if the bright surface is obscured by dust or corrosion. The purpose of insulation is to get low fuel costs. This is generally obtained by blending still air and solid materials having low cost and low conductance, assisted in some cases by the use of reflective metallic surfaces. E. C. Petrie

Peat fiber fabrics as a base for artificial leather, oilcloth and linoleum. Felix Fritz. *Nitrocellulose* 10, 183–4 (1939).—A review. E. M. Symmes

Finishing fancy and saddle leather substitutes made from synthetic rubber. M. E. Slepyan. *Kozhevenno-Obuvnaya Prom.* 18, No. 3, 29(1939).—The following compn. was used satisfactorily for finishing fancy and saddle leather substitutes made from synthetic rubber: casein 6 kg., petrolatum 10% (of casein), stearin 6%, glycerol 80%, liquid ammonia 6% and formalin 15%. B. Z. Kamich

Chemistry's new "building blocks." Sydney B. Self. *Barron's* **19**, No. 49, 13–16(Dec. 4, 1939).—A description of some of the new products of the principal chem. companies. A. M. Patterson

Acryloids. W. T. Pearce. *Drugs, Oils & Paints* **54**, 382(1939).—Acrylates are polymers of the esters of acrylic and methacrylic acids. All are of water-white color, good color retention in direct sunlight, diffused light or when baked at normal temps., all possess good elec. properties and are very resistant to water, acids, alkalies and chem. fumes. Solns. of these resins are thermoplastic. These resins are compatible with nitrocellulose, most chem. plasticizers, aromatic hydrocarbons, ketones, esters, ether alcs. and ether esters. Several grades are noted. A 25% dispersion in water of an acrysol is marketed which is especially useful for application to rubber or rubberized surfaces. W. H. Boynton

Determination of dry residue in shoe dressings. P. S. Kofman and P. S. Kopelovich. *Kozhevenno-Obuvnaya Prom.* **18**, No. 3, 19(1939).—A sample of the shoe dressing is carefully spread out by rubbing between two 9 × 12 cm. weighed glass plates; the plates are then weighed and dried in an oven at 100–150°. If the dry residue is 30–40% or higher a 1.5–2-g. sample should be used, if 15–30% a 0.75–1.5-g., and if 10–15% a 0.2–0.75-g. Differences between detns. do not exceed 0.2% and the accuracy is sufficient for control work. B. Z. Kamich

Recent developments in the fumigation of buildings, stored foods and other materials. A. B. P. Page and O. F. Lubatti. *Chemistry & Industry* **1939**, 1001–6. E. H.

Fireproofing mine shafts. Joseph R. Guiteras. *Can. Mining J.* **60**, 606–8(1939).—A review of various methods. W. H. Boynton

Fog or mist suitable for military camouflage or plant protection. Paul Kronenberg. U. S. 2,173,756, Sept. 19. App. is described, and a process of producing fog or mist which comprises applying in divided liquid form an org. substance which leaves no solid residue when burned and selected from the group consisting of crude paraffin oil, solid paraffin, lignite oil, crude petrolatum, naphthalene, anthracene, oleic acid, mineral oils, tallow, tar and pitch, to an oxidizing catalyst consisting of a metallic oxide on a porous carrier in the presence of air, such substance being applied in such quantities as will produce a partial and flameless combustion.

Plastic, molding and coating compositions. Jack D. Robinson (to National Aniline & Chemical Co.). U. S. 2,173,181, Sept. 19. Resins or gums or cellulose esters or ethers are plasticized with the alpha-phenyl ether of diacetin or other aryl ethers of glyceryl mono- and diacetates, propionates, butyrates, laurates, lactates, benzoates, cresotinates, salicylates, naphthoates or cyclohexanoates.

Granular plastic material suitable for molding. Robert C. Hills and Maxwell M. Barnett. U. S. 2,174,000, Sept. 26. A granular plastic material is produced by dissolving an alkali metal sulfide and S in water 500 cc., heating the resulting soln. to 90°, treating it with 500 cc. of a 37% formaldehyde soln., filtering, washing and drying.

Oil compositions. Bakelite Ltd. Brit. 507,770, June 20, 1939. Oil compns. comprise a processed oil and a special oil-sol. phenol-aldehyde resin. The processed oil is obtained by bodying by blowing or oxidizing drying or semidrying oils and the resin is obtained by condensing a substituted phenol with CH_2O in the presence of a basic catalyst until a resin is formed that has a m. p. not less than 50° and is curable at 160° in 1–10 min. The compns. may be used as *coating, molding, calendering, floor covering* and *impregnating compns.* Among examples, a resin obtained by condensing (1) a high-boiling phenolic compd. with aq. CH_2O in the presence of $(CH_2)_6N_4$ is blended with heated blown soybean oil with or without blown fish oil, and (2) *p*-phenylphenol with aq. CH_2O in the presence of $Ba(OH)_2$ is blended with blown fish oil in the presence or absence of fillers (asbestine, clay, wood flour, cotton flock), pigments (C black, TiO_2) and hardening agents (PbO, $(CH_2)_6N_4$ or paraform).

Resins. Bakelite Ltd. Brit. 507,013, June 7, 1939. Resins are produced by causing a phenol to react with a polyvinyl compd. and causing the product to react with an aldehyde. The products may be dissolved in org. solvents to form coating compns. and adhesives and may be used in laminated bodies, e. g., safety glass. Among examples, PhOH and polyvinyl acetate are refluxed and the product is then condensed with paraformaldehyde to a rubbery material.

Synthetic resins. Wm. H. Moss. Brit. 506,999, June 5, 1939. Resins are prepd. by causing a phenol, an aromatic sulfonamide and a compd. contg. at least 2 halogen atoms attached to different C atoms of an aliphatic grouping to react. The reaction may be conducted in aq. alkali under reflux or on the fiber of textile materials such as cotton, linen, regenerated cellulose or cellulose derivs., e. g., di-(4-hydroxyphenyl)dimethylmethane and *p*-toluenesulfonamide (I) in mildly alk. soln. are applied to cellulose acetate, followed by glycerol dichlorohydrin (II). The products may be molded, used in *coating compns.*, or for *crease-proofing textiles.* In examples, resins sol. in Me_2CO, alc. and C_6H_6 are prepd. by condensing diphenylolpropane, I and *sym*-II in the mol. proportions (1) 1:1:2 and (2) 1:1:1, and cellulose acetate rayon is crease-proofed by immersion in an alc. soln. of the product of (1). Compns. may comprise the resins together with film-forming substances, e. g., nitrocellulose, org. esters of cellulose, cellulose ethers and vinyl resins. The resin may be pptd. from soln. onto a finely divided cellulose deriv. or may be absorbed thereby from soln. or dispersion. Solns. of these compns. in volatile solvents, with or without plasticizers, medium- or high-boiling solvents, natural or synthetic resins, fire retardants, pigments, dyes or effect materials may be used as adhesives or coating or impregnating compns., e. g., for protecting rubber or other insulation, or as insulating materials. Solns. contg. the resins and cellulose esters or ethers may be formed into threads or films or used as *airplane fabric dopes.* Those contg. coloring materials may also be used as *printing inks for plastic material*, e. g., cellulose acetate films. The compns. may be molded.

Synthetic resins. I. G. Farbenind. A.-G. (Karl Keller and Werner Zerweck, inventors). Ger. 679,341, Aug. 7, 1939 (Cl. 12*p*. 10). Addn. to 669,807 (*C. A.* **33**, 5547[2]). Amino and hydrazine compds. contg. two 5-membered rings in the mol. are condensed with low mol. fatty aldehydes to give resins. Thus, guanazoguanazole (obtained by heating an aq. soln. of guanazole-HCl with dicyanodiamide) is condensed with CH_2O. Other examples are given. In each case, the structural formula of the double-five-membered ring compd. used as the starting material is given.

Synthetic resins. Soc. pour l'ind. chim. à Bâle (Wilhelm Kraus, inventor). Ger. 679,874, Aug. 17, 1939 (Cl. 12*o*. 17.05). Hardenable resins produced by condensing $(CH_2)_6N_4$, CH_2O and urea or thioureas are caused to react with low-mol. carboxylic acid amides or urethans in less than equimol. amts. to give water-free press masses. Examples are given.

Synthetic resin compositions. Vernay Patents Co. Brit. 507,501, June 15, 1939. Elements for use as the

control element of a thermostat are prepd. by dissolving a synthetic rubber in a molten normally cryst. material, e. g., Ph_2, dibromo- or dichloro-benzene, the m. p. of which is below the decompn. temp. of the synthetic rubber and is such that it melts or fuses in the temp. range over which the thermostat is to operate, uniformly distributing in the mixt. a finely divided solid material that is a good conductor of heat, e. g., graphite, C, Sb, Al, Cu, and forming the mixt. into a body of the desired shape. Suitable synthetic rubbers are polymers of vinyl chloride or chlorobutadiene.

Synthetic resinous products. R. P. R. Association (formerly Rubber Producers Research Association), Cyril A. Redfarn and Philip Schidrowitz. Brit. 507,995, June 23, 1939. These are obtained by treating rubber (I) simultaneously with maleic anhydride (II) and a phenol at elevated temp. and then further condensing the I-II-phenol product with an aldehyde. The 1st stage may be accelerated by the presence of O or air and catalysts, e. g., H_2SO_4 or $(COOH)_2$; the 2nd stage may be conducted in acid or alk. medium. Molding compns. are obtained by incorporating fillers, mold lubricants, coloring substances and hardening agents with the resin by hot milling. Rubber vulcanizing ingredients may be added to the molding compns.

Synthetic resinous products. R. P. R. Association, Ernest H. Farmer and Jack W. Barrett. Brit. 507,996, June 22, 1939. Products ranging from elastic, rubber-like materials through fibrous substances to brittle resins are obtained by causing maleic anhydride (I) to react with rubber (II) in soln. and maintaining the mixt. at elevated temp. Catalysts or condensing agents, e. g., Bz peroxide, Bz tolnyl peroxide, may be used in amts. up to 30% of the wt. of the II. As a modification, the I and II may be heated together with a vinyl compd., e. g., styrene, vinyl acetate, Et α-methacrylate. The II is preferably in dil. soln. in a solvent such as toluene, xylene, decalin, cyclohexane or C_6H_6.

Vinyl resin compositions. I. G. Farbenindustrie A.-G. Brit. 507,600, June 19, 1939. Compns. for impregnating and insulating, e. g., for cables, condensers and transformers, comprise chlorinated $C_{10}H_8$ or chlorinated Ph_2 and not more than 11% thereof of polyvinyl carbazole.

Phenolic resinous product. Victor H. Turkington and Wm. H. Butler (to Bakelite Corp.). U. S. 2,173,346, Sept. 19. A process for producing a sol. condensation product capable of undergoing further substantial condensation on the application of heat and of forming uniform homogeneous products when treated with an excess of substantially neutral resins, drying oils or mixts. thereof, comprises treating (1) a phenol substituted in the para-position by a hydrocarbon radical having 4–7 C atoms, in the absence of unsubstituted phenol and (2) a substantial excess of CH_2O over the equimol. proportion, the reaction being carried out with the aid of a strong alk. catalyst.

Resinous products from aldehydes and acrylic amides. Daniel E. Strain (to E. I. du Pont de Nemours & Co.). U. S. 2,173,005, Sept. 12. Products which are suitable for coatings or molded articles are formed by the reaction of monomeric amides of the acrylic acid series having the general formula $H_2C{-}C(R)COOH$ in which R may be H or a hydrocarbon radical, with aliphatic aldehydes of lower mol. wt. such as CH_2O.

Polyvinyl acetal resin compositions. Dr. Alexander Wacker Gesellschaft für elektrochemische Industrie G. m. b. H. Brit. 507,247, June 13, 1939. Materials, e. g., for hats, are stiffened by treatment with a compn. comprising a H_2O-insol. polyvinyl alc. ester-acetal resin that is prepd. from a polyvinyl alc. or ester having a viscosity of 100 or less; it contains 50–70% acetal groups, 10–30% ester groups and 15–25% OH groups, or has a viscosity above 100 and contains said groups in the proportions 40–60, 25–50 and 5–15%, resp. The resins may be prepd. by simultaneous sapon. of a polyvinyl alc., e. g., acetate, and acetalization, e. g., with AcH; or by acetalization of polyvinyl alc. in the presence of a carboxylic acid, e. g., AcOH. Alternatively, H_2O-insol. polyvinyl alc.-ester-acetals in general may be used, in conjunction with EtOH-sol. urea-CH_2O resins, acetylated polyglycols or polyglycerols, bleached shellac, or interpolymers of vinyl compds., e. g., esters, with drying or semidrying oils, or mixts. thereof. Among examples straw hats are treated with a soln. in EtOH, AcOEt and toluene of polyglycerol acetate and a resin prepd. from polyvinyl acetate of viscosity about 500 and contg. acetal groups 65, ester groups 25 and OH groups 10%.

Synthetic resin coating compositions. Bakelite Ltd. Brit. 507,769, June 20, 1939. A coating compn. capable of giving oil- and grease-resistant films comprises a blown and (or) polymerized oil, a heat-convertible synthetic resin and a nonheat-convertible synthetic or natural resin. Among examples, compns. are prepd. contg. (1) a condensate of tar acids and CH_2O prepd. in the presence of NH_3, blown fish oil and oxidized abietic acid, the blend being aftertreated with paraformaldehyde or the initial oxidized abietic acid and blown oil being treated with glycerol if desired, and (2) a condensate of *p*-phenylphenol and CH_2O prepd. in the presence of an acid catalyst, $(CH_2)_6N_4$, cumar resin and blown fish oil. The compns. may be used to coat paper, cardboard, pulp board, cloth, asbestos, canvas and the coated material used to manuf. boxes, oilproof and chemically resistant containers, etc.

Polyvinyl acetal resin films. The Fiberloid Corp. Brit. 508,105, June 19, 1939. A continuous sheet of polyvinyl acetal resin is prepd. by homogeneously mixing resin and a compatible plasticizer therefor and simultaneously or subsequently softening by heat and extruding the mixt. through the slot of a die, all in the absence of a volatile solvent. Specified mixes contain a polyvinyl acetate about 90% hydrolyzed and about 80–85% acetalized with CH_2O, mixed with diethyleneglycol dipropionate with or without camphor or glycol laurate.

Decomposition products of synthetic resins. Phillips Petroleum Co. Brit. 507,339, June 14, 1939. The complex products obtainable by the reaction of SO_2 with aliphatic compds. contg. an olefinic linkage are decompd. by reaction with an inorg. or org. basic reagent or a soln. thereof. The products so obtained include neutral oils contg. C, H, S and O and salts of S-contg. org. acids, probably sulfinic acids; the latter may be oxidized, e. g., with air, O or $KMnO_4$. The oily products may be used (a) *for extg. aromatic hydrocarbons from hydrocarbon mixts.*, e. g., cracked gasolines, (b) *for sepg. lubricating oils from paraffin*, (c) *as plasticizers* for the complex compds. obtainable from SO_2 and unsatd. compds., or (d) *as rubber softeners*. The alkali salts of the S-contg. acids may be used as soap substitutes and emulsifying agents. Among examples, butene-2, allyl alc. or undecylenic acid is treated with an equimol. proportion or more of SO_2 in sunlight or ultraviolet light or in the presence of a catalyst, e. g., nitrate of Ag, Li, NH_4 or K; excess SO_2 is allowed to evap. and the residual resin is treated with hot NaOH soln.; the product is extd. with Et_2O to recover neutral reaction products and the residue from the Et_2O extn. is acidified and extd. again, with or without intermediate oxidation.

Resinous condensation products. I. G. Farbenindustrie A.-G. Brit. 508,016, June 21, 1939. These are obtained by esterifying glycolic or lactic acid with a polyhydric alc., e. g., glycol, glycerol, 1,1,1-trimethylolpropane, erythritol, pentaerythritol, and then condensing with a polybasic acid, e. g., phthalic, succinic, adipic, methyladipic, maleic, fumaric and a monocarboxylic acid free from alc. OH groups, e. g., stearic, linseed or wood oil acids, montanic, abietic, BzOH or monocarboxylic acids obtained by the oxidation of paraffin. A solvent is advantageously added and H_2O removed by azeotropic distn., removal being accelerated by a current of indifferent gas. The resins obtained have good compatibility with pigments, e. g., ZnO, and with nitrocellulose.

Phenol-aldehyde condensation products. I. G. Farbenindustrie A.-G. Brit. 507,208, June 8, 1939. Masses capable of hardening rapidly in the cold are prepd. by mixing a liquid phenol-CH_2O resin with an acid or neutral hardening agent and at least 1 aliphatic ester of an inorg.

acid. The hardening agent and the ester may be added separately. In an example, a mixt. of *p*-toluenesulfonyl chloride, $BaSO_4$ and powd. quartz is mixed with a liquid PhOH-CH_2O resin and glycolchlorohydrin, dichlorohydrin, dichloropropanol, epichlorohydrin, ethylene chloride or Et_2SO_4 and the resulting mass allowed to harden.

Phenol-acetaldehyde condensation products. Ellis-Foster Co. Brit. 507,658, June 14, 1939. Phenol-AcH resins are heated to at least 180° in the presence of a small amt. of an oxalate or $(COOH)_2$ to decolorize them. The condensation of the phenol and AcH is preferably effected in the presence of an acid having a dissocn. const. of $2\ 10^{-1}$–$1\ 10^{-3}$, e. g., $(COOH)_2$, and acid of P, and the phenol may be pretreated with or treated simultaneously with the condensation with a small amt. of an aldehyde of greater mol. wt. than AcH, or with methyl ethyl ketone or a higher ketone or with a diphenylolbutane or other diphenylol-substituted hydrocarbon. Among examples, (1) cresylic acid is condensed with paraldehyde in the presence of $(COOH)_2$, heated to 220°, blended by being heated with tung oil and dissolved in naphtha *to yield a varnish*, and (2) xylenol is condensed with a mixt. of gaseous AcH and hydrocarbon gases in the presence of $(COOH)_2$ and the condensate, after having been heated to 210°, is blended with linseed and tung oils and dissolved in naphtha to *yield a varnish*.

Urea-aldehyde condensation products. I. G. Farbenindustrie A.-G. Brit. 507,175, June 12, 1939. Masses for embedding specimens or tissues and for filling up parts of optical app., etc., are produced by an acid condensation of urea and (or) thiourea with CH_2O in the presence of a polyhydric alc. or partial ester or ether thereof, or of sugar and H_2O, H_2O being distd. off during and after condensation and the final H_2O content of the resin being 10–50%. At least 2 mols. CH_2O is employed per mol. of urea, the amt. of polyhydric alc., etc., being 0.5–4 times the wt. of urea. Among examples, (1) a soln. of urea in aq. CH_2O is allowed to flow, under reduced pressure, into glycerol in which is dissolved a small amt. of phthalic anhydride, the temp. being maintained at 70–75° and H_2O being vaporized continuously; the resulting resin is dild. with alc. to a dry resin content of 75%, a little aq. $(COOH)_2$ soln. is added, and the soln. is degasefied under reduced pressure and allowed to flow into a display glass in which is arranged, e. g., a bunch of heather, the filled glass being sealed with rubber, and (2) a resin soln. is prepd. from urea dissolved in aq. CH_2O and a glycol mixt., consisting mainly of monodiglycol ether, with a little adipic acid and is used as in (1).

Urea-formaldehyde condensation products suitable for lacquers. Sydney L. M. Saunders and Leonard W. Coveney. U. S. 2,174,012, Sept. 26. A process for prepg. a synthetic resin compn. comprises heating in the presence of an acid catalyst a primary condensation product of urea and CH_2O dispersed in a monohydric alc. solvent having at least one H atom attached to the hydroxyl C in the presence of sufficient CH_2O to bring the total CH_2O present in both the free and combined state into excess of that corresponding to dimethylol urea, and distg. off alc. solvent along with water, both any originally present in the reaction ingredients and that formed during the condensation reaction; the heating is continued until the product is sol. in hydrocarbon solvents and the acidity of the alc. solvent is maintained throughout the heating.

Condensation products. Compagnie nationale de matières colorantes et manufactures de produits chimiques du Nord réunies établissements Kuhlmann. Ger. 679,956, Aug. 17, 1939 (Cl. 12*o*. 26.02). Condensation products from polyhydric alcs., polybasic acids, natural resins and drying oils are obtained by (1) condensing excess of a polyhydric alc. with a polybasic aromatic acid and a natural resin or a mixt. of natural resins, (2) heating the product to above 210° in an autoclave with linseed oil, till a homogeneous mass is obtained. Thus, glycerol, phthalic anhydride and colophony are condensed and the product is condensed with linseed oil to give a thick fluorescent product. Other examples are given.

Electric insulation. Karl E. Prindle (to Dobeckmun Co.). U. S. 2,173,726, Sept. 19. There is used, in a dynamo-elec. machine having a core and windings, a resilient laminated material insulating the core from the windings and having at least 2 coextensive plies thermoplastically secured together, one formed of paper consisting essentially of rag and sulfite fibers and the other of cellulose acetate.

Electric insulation. The British Thomson-Houston Co. Ltd. Brit. 506,560, May 31, 1939. Insulation comprises a porous cellulosic material impregnated with a dielec. substance consisting wholly or partly of a chlorinated diphenylene oxide that is solid at normal temps., particularly with a mixt. of chlorinated diphenylene oxide and pentachlorobiphenyl. Direct chlorination of diphenylene oxide, e. g., at 125–180°, in the presence of a catalyst, e. g., Fe, Sb or Fe or Sb chloride, produces solid products of wax-like consistency and high dielec. consts.

Heat insulation. Theodore B. Slisz and Clyde C. Schuetz (to United States Gypsum Co.). U. S. 2,173,815, Sept. 19. A sheet of metal foil is adhesively secured to a base material such as paper or sheet asbestos, and the material is thereafter indented to a depth sufficient to cause rupture of the metal foil adjacent the indentations.

Magnesia heat insulation. Earle R. Williams (to Johns-Manville Corp.). U. S. 2,172,861, Sept. 12. Insulation is prepd. by a method which involves treating a dil. aq. suspension of finely divided MgO with CO_2 to form $MgCO_3$, mixing the resulting aq. product with asbestos fibers and a small proportion of a water-sol. soap, molding, heating to form Mg basic carbonate and effecting setting for retention of shape, removing the product from the mold and further heating it for drying.

Insulating compositions. Standard Telephones and Cables Ltd., Thomas R. Scott and Archibald A. New. Brit. 508,035, June 26, 1939. Insulating materials, which may be in the form of plates, tapes or films, comprise glass or quartz fibers or filaments embedded in a solid polymerized olefin. An org. dust having a permittivity greater than 5 may also be present, e. g., glass, mica, quartz or ceramic dusts.

Impregnated material suitable for insulation, containers, etc. Christopher Luckhaupt. U. S. 2,173,882, Sept. 26. Porous material such as paper or pulp board, which is insol. at elevated temp. in terpinol hydrate mixed with triphenyl phosphate, is impregnated with these substances so that it is rendered nonpermeable to water and alc. App. for effecting the treatment is described.

Alkylated chloro aromatic hydrocarbon mixtures. Robert R. Dreisbach (to Dow Chemical Co.). U. S. 2,174,069, Sept. 26. A product which may be used as a dielectric or for plasticizing synthetic resins, etc., is produced by treating, in the presence of a Friedel-Crafts catalyst such as $AlCl_3$, at least one chlorinated aromatic hydrocarbon of the benzene series having not more than 4 Cl atoms attached to the benzene nucleus, such as chlorobenzenes, with a complex mixt. of gaseous olefins such as may be obtained by cracking a petroleum fraction.

Cold-workable dielectric composition suitable for sealing cable conduits, etc. Silvio Pellerano. U. S. 2,174,164, Sept. 26. A plastic, adhesive, cold-workable non-setting, waterproof dielectric compn. is formed of a coumarone-indene resin, chlorinated paraffin, a heavy solvent plasticizing oil and inert fillers such as asbestos and powdered soapstone.

Cables. Vereinigte Aluminium-Werke A.-G. and Siemens-Schuckertwerke A.-G. Brit. 508,015, June 20, 1939. Cables are sheated with Al of at least 99.9% purity, which, owing to this high purity, has a tensile strength of 3–10 kg. per sq. mm. and an elongation of 30–50%. The Al, which may be formed by subjecting normal electrolytic Al to a form of fusing electrolysis in the so-called 3 layer system, may be applied to the cable by extrusion or in the form of bands.

Cables. Standard Telephones and Cables Ltd., Thomas R. Scott and John K. Webb. Brit. 508,034, June 26, 1939. A power cable comprises lappings of fibrous material impregnated with polymerized material, cable compd. permeating the space between the lappings.

Lappings of fibrous material impregnated with compd. may also be included, either between the polymer-impregnated lappings and the sheath or interleaved with the polymer-impregnated lappings. The cable may be mass impregnated or oil filled. The polymer may be polystyrene, which may be plasticized as described in Brit. 490,814 (*C. A.* **33**, 1062[7]) or blended with other polymers, or the insulation may comprise material treated as described in Brit. 454,923 (*C. A.* **31**, 1909[7]).

Cables. British Insulated Cables Ltd., Francis J. Brislee and Laurence Macfarlane. Brit. 508,916, June 29, 1939. A cable comprises 1 or more conductors insulated with siliceous material dried at 350–600° and enclosed in a sheath of Al or an alloy in which Al predominates. Asbestos may be applied as a roving and impregnated with Na silicate soln.

Adhesives. Wingfoot Corp. Brit. 507,327, June 13, 1939. These comprise a natural or artificial rubber latex as the disperse phase of an emulsion with a soln. or dispersion of a condensation deriv. of rubber as the continuous phase. The latex may be vulcanized or may contain polymerized chloroprene, and the rubber condensation deriv. is obtained by treating rubber with the halide of an amphoteric element, e. g., as described in Brit. 306,390 (*C. A.* **23**, 5062). Emulsifying agents, e. g., solns. of casein or rosin, may be used. The adhesive may be applied to rayon that is to be incorporated in rubber tires or belts.

Wetting agent. Böhme Fettchemie-G. m. b. H. (Heinrich Bertsch, inventor). Ger. 676,343, June 1, 1939 (Cl. 8*o*). Addn. to 659,528 (*C. A.* **32**, 6773[5]). The products obtained by esterifying low mol. monohydric aliphatic alcs. contg. up to 8 C atoms, with the H_2SO_4 esters of unsatd. fatty acids, or with hydroxy fatty acids contg. the H_2SO_4 ester group or the COOH group or both, and with a no. of C atoms corresponding to castor oil, are used as wetting agents in the form of their NH_4 salts. Examples mention the NH_4 salt of hydroxystearic sulfuric acid isopropyl ester, the NH_4 salt of the product from BuOH, and castor oil fat acid, and the NH_4 salt of ricinoleic sulfuric acid Bu ester.

Wetting agents, etc. I. G. Farbenindustrie A.-G. Brit. 507,207, June 8, 1939. Hydrohalides of substituted isothioureas are made by causing thiourea or a deriv. thereof contg. at least 1 reactive H atom and capable of reacting in the iso-form to react with a halomethyl compd. of formula $RXCH_2Y$ or $R'X'CH_2Y$, where R is an aliphatic, aliphatic-cycloaliphatic or aliphatic-aromatic radical contg. at least 11 C atoms, which may contain substituents and (or) may contain an O, S or N atom as a hetero-atom in an aliphatic C chain or as a bridge directly linking an aliphatic portion of the radical to a cycloaliphatic or aromatic nucleus, R′ is an alkyl radical, which may contain a substituent, X is hydroxyphenyl in which the OH group is in *o*- or *p*-position to the halomethyl group, or is -CON(R″)- or -OCON(R″)- or -NHCON(R″)-, X′ is -CON(R)- or -OCON(R)-, R″ is H or alkyl and Y is a halogen atom. The products are sol. in, or capable of being emulsified with, H_2O and may be used in the *treatment of textiles*. Among examples, thiourea is caused to react with the chloromethyl compds. obtained by the reaction of H halides and paraformaldehyde on (1) stearic acid amide, (2) 9,10-dichlorostearic acid amide, (3) *N*-dodecylacetamide, (4) *p*-isotetradecylphenoxyacetic acid amide, and triethylthiourea is caused to react with the *N*-chloromethyl compd. of the amide from hardened train oil fatty acid.

Wetting agents, etc. Edmund Waldmann and August Chwala. Brit. 507,766, June 20, 1939. Addn. to 460,858 (*C. A.* **31**, 4748[8]). Products having wetting, dispersing, cleansing and foaming properties are obtained by heating to about 100–220°, so far as possible in the absence of H_2O, a salt of an aliphatic halohydroxysulfonic acid contg. at least 3 C atoms with an imidazoline having at least 10 C atoms. The imidazoline bases may be liberated from their salts by the addn. of anhyd. AcONa or anhyd. alk. salts, e. g., Na_2CO_3, borax, Na_3PO_4. In an example, powd. Na γ-chloro-β-hydroxypropane-α-sulfonate is heated with heptadecenylimidazoline and calcined, powd. Na_2CO_3 stirred into the resulting mass.

Sulfated alkoxy cyclohexanols. Herbert A. Lubs (to E. I. du Pont de Nemours & Co.). U. S. 2,174,131, Sept. 26. *Wetting, dispersing, deterging* and *emulsifying agents* suitable for use as *dye-bath aids* and in general as textile assistants, etc., are produced by sulfonating dodecyloxycyclohexanol and various related compds. The products form stable Na salts.

Acid-substituted hydroxy alkylamines. Wolf Kritchevsky. U. S. 2,173,058, Sept. 12. Compds. which may be used as *emulsifying, dispersing* or *wetting agents*, e. g., for dispersing vat dyes or oils in aq. media, and which may involve the substitution of one, two or three H atoms of the OH groups of triethanolamine or the like by a higher fatty acid radical such as stearyl, linoleyl, abietyl or lauryl, are produced by condensing a hydroxy alkylamine with a higher fatty acylating compd., as by heating triethanolamine for several hrs. at 150–175° with stearic acid or oleic acid.

Sulfated acyloins. Clyde O. Henke and Joseph L. Richmond (to E. I. du Pont de Nemours & Co.). U. S. 2,174,127, Sept. 26. By the sulfation of capryloin, caproin or mixed acyloins, *wetting, dispersing, deterging* and *emulsifying agents* are obtained, suitable for use as *dye-bath assistants* and in general as textile assistants. Several examples with details are given.

Alkylolamine derivatives (detergent, emulsifying and flotation agents, etc.). Morris B. Katzman and Albert K. Epstein (to Emulsol Corp.). U. S. 2,173,448, Sept. 19. Reaction products having a light color and substantial freedom from odor result from the reaction of an alkylolamine and higher carboxylic acids contg. at least 6 C atoms, their esters, anhydrides, and mixts. thereof, at temps. above 100° while steam is passed through the reaction mass, and the reaction mixt. rapidly cooled while a steam atm. is maintained at least until partial temp. reduction has been effected. Among the higher carboxylic acids which may be employed in the reaction as such or in admixtures of any two or more or in the form of their anhydrides are the following: caproic, capric, caprylic, hydroaromatic acids such as abietic acid, aromatic acids such as benzoic, benzoylbenzoic, naphthoic, toluic, and naphthenic acids, hydroxystearic acids, montanic acid, satd. and unsatd. fatty acids of higher mol. wt. particularly those derived from natural fats and oils, such as palmitic acid, stearic, lauric, myristic, melissic, oleic, ricinoleic, linoleic, or mixed higher fatty acids derived from animal or vegetable fats and fish oils such as lard, oleo oil, coconut oil, corn oil, cottonseed oil, soybean oil, partially or completely hydrogenated vegetable oils such as cottonseed oil, corn oil, sesame oil, and fatty acids of various waxes such as beeswax and carnauba wax. Among the esters of higher carboxylic acids which may be utilized in the reaction, most important are the naturally occurring triglyceride oils and fats and the waxes which are esters of higher carboxylic acids and monohydric alcohols. These may be derived from animal and vegetable sources and include the following: cottonseed oil, coconut oil, corn oil, sesame oil, soybean oil, lard, oleo oil, stearin, fish oils such as sardine oil, and the oils whether partially or completely hydrogenated, beeswax, carnauba wax, etc. Others include the esters of lower mol. wt. alcs. and higher carboxylic or higher fatty acids, examples of which esters are ethyl stearate, butyl laurate, propyl palmitate, ethyl oleate, etc. Particularly satisfactory products have been obtained with coconut oil. Various examples with details are given for the obtainment of products suitable for use in *cosmetic creams* and for other purposes.

Condensation products suitable for use as wetting or cleansing agents, etc. Albert F. Bowles and Saul Kaplan (to Richards Chemical Works). U. S. 2,172,747, Sept. 12. Urea, thiourea or gelatin is condensed with an alkylene oxide such as ethylene oxide and with an aldehyde contg. 8–20 C atoms, such as "cocoanut aldehyde" (suitably by heating at 180–200° in the presence of an

alkali metal hydroxide or acetate). Numerous examples with details are given.

Condensation products. I. G. Farbenind. A.-G. (Heinrich Ulrich, inventor). Ger. 676,407, June 3, 1939 (Cl. 12*p*. 15). Addn. to 656,934 (*C. A.* **32**, 4356[8]). In making products by the method of 656,934, by condensing a ketone with polymerized ethylenimine and C_3H_4O, β-keto carboxylic acid esters are used as the ketone. The example mentions acetoacetic ester. The products are used as *assistants in the leather, textile, varnish* and *rayon industries*.

Leather substitute. I. G. Farbenind. A.-G. (Hans Fikentscher, inventor). Ger. 679,825, Aug. 15, 1939 (Cl. 39*b*. 4.02). Leather waste is mixed with an aq. emulsion contg. unsatd. polymerized aliphatic compds., the water removed and the resulting mass brought to desired shape. Thus, a 25% aq. dispersion of polymerized Et acrylate, obtained by polymerizing the monomeric acrylate in the presence of the Na α-hydroxyoctodecane sulfonate and H_2O_2, is mixed with chrome leather chips to form a paste which is dried and pressed between hot rollers. Cf. *C. A.* **33**, 6999[1].

Polymerized compounds. I. G. Farbenind. A.-G. (Christoph Dörfelt and Kurt Billig, inventors). Ger. 679,944, Aug. 16, 1939 (Cl. 39*b*. 4.02). Alkylideneacetic acid esters are polymerized and mixed with other polymerizable compds. Thus, a mixt. of vinyl acetate and ethylideneacetic acid esters is treated with benzoyl peroxide to give a polymerization product comprising a transparent, colorless, glassy block. Other examples are given.

Polymerized masses. Deutsche Celluloid-Fabrik. Ger. 679,896, Aug. 15, 1939 (Cl. 39*b*. 4.02). The resistance to light and heat of synthetic polymerizates contg. Cl is improved by extg. with org. liquids which do not cause swelling and which dissolve out the low-mol. constituents. Thus, chlorinated polyvinyl chloride is extd. with 94% alc. contg. 2% toluene at 40° in powder form.

Polymerization products of vinyl esters. I. G. Farbenind. A.-G. (Arthur Voss and Werner Heuer, inventors). Ger. 679,943, Aug. 16, 1939 (Cl. 29*b*. 4.02). Addn. to 666,866 (*C. A.* **33**, 2216[8]). Mixts. of org. vinyl esters and other unsatd. org. compds. are polymerized by using peroxides of fatty acids with at least 4 C atoms in the mol. Thus, a mixt. of vinyl acetate and the dimethyl ester of maleic acid is treated with oleic acid peroxide to give a viscous product. Other examples are given.

Vinyl polymerization products. The Distillers Co. Ltd., Herbert M. Stanley and Hanns P. Staudinger. Brit. 506,812, June 5, 1939. Elec. insulation members are formed from a material prepd. by polymerizing polystyrene in a solvent, e. g., isopropylbenzene, contg. 0.001–1% of a diolefin hydrocarbon contg. at least 2 aliphatic >C :CH_2 groups sepd. by at least 2 C atoms, e. g., *p*-divinylbenzene, α,α′-dimethyl-*p*-divinylbenzene, divinylacetylene, 4,4′-divinylbiphenyl, 1,4-divinylnaphthalene, *p*,*p*′-divinylstilbene, 1,3,5-hexatriene.

Vinyl polymerization products. I. G. Farbenindustrie A.-G. Brit. 506,926, June 6, 1939. Rubber-like products are obtained by incorporating *N*-vinylcarbazole with a preponderant amt. of solid, highly polymerized isobutylene, the amt. of the carbazole being at least 2% of the mixt., and heating the mixt.

Polymerized vinyl compounds. I. G. Farbenind. A.-G. (Rudolf Bappert and Georg Wick, inventors). Ger. 679,897, Aug. 18, 1939 (Cl. 39*b*. 4.02). A continuous method for prepg. polymerization products from vinyl compds. consists in passing the monomeric vinyl compd. through a tube of emulsified substance such as Na α-hydroxyoctodecanesulfonate, the solid polymerizate being collected at the end of the tube. An example is given.

Hydrocarbon polymer compositions. Kabelwerk Vacha A.-G. Brit. 506,855, June 6, 1939. An elec. insulating material consists of a mixt. of polystyrene and polyisobutylene, the latter being 10–95% of the mixt., with or without an addn. of bitumen. The ingredients are mixed in a kneader at an elevated temp., e. g., 100–200°, and are worked up by extruding or calendering while they are hot. A suitable solvent, e. g., CCl_4, or monomeric styrene, may be added to facilitate extrusion, the styrene being polymerized during the subsequent shaping.

Hydrocarbon polymer compositions. Standard Telephone and Cables Ltd., Thomas R. Scott and Malcolm C. Field. Brit. 507,323, June 9, 1939. An elec. insulating material is prepd. by adding a polymerized aliphatic monoolefin contg. less than 6 C atoms to a monomeric or partially polymerized mononuclear aromatic vinyl hydrocarbon, allowing the olefin to swell or dissolve in the aromatic compd. and then subjecting the mixt. to the action of heat to polymerize the aromatic compd. Alternatively, the material may be prepd. by dissolving the polymerized olefin and the polymerized vinyl hydrocarbon in a common solvent and then heating the soln. to drive off the solvent. The monoölefin may be C_2H_4, C_3H_6, C_4H_8 or C_5H_{10} and the vinyl hydrocarbon may be styrene. Addnl. substances may be incorporated in the insulating material, e. g., by admixt. with the vinyl hydrocarbon prior to polymerization thereof, or by dissolving in the soln. Specified addns. are rubber, balata, guttapercha, with or without a rubber plasticizer such as ceresin, hydrocarbon waxes, and, when the material contains polystyrene, a plasticizer comprising a stable homocyclic C compd. having 2 or 3 fused rings, a b. p. higher than 240°, a low elec. moment and capable of swelling polystryrene, e. g., phenanthrene, isoamylnaphthalene, α-propylnaphthalene, fluorene or β-naphthyl methyl ether.

Textile cleansing and wetting compounds, etc. Meindert D. Rozenbroek. U. S. 2,173,638, Sept. 19. A compd. suitable for use in various textile treatments is produced by the reaction of an ether made from a polyhydric alc. and an aliphatic alc. of high mol. wt., such as the monostearyl or monolauryl ether of glycol, or an ester made from a polyhydric alc. and an aliphatic acid of high mol. wt., with an inorg. acid derived from P, or PCl_3 or P_2O_5, and sulfonating the resulting inorg. acid ester.

Detergent compounds. Cortes F. Reed (50% to Charles L. Horn). U. S. 2,174,110, Sept. 26. A method of forming substitution products contg. S, Se or Te and O and a halogen, from hydrocarbon-contg. compns. such as paraffin, involves treating the latter with a mixt. of a halogen such as Cl and a dioxide of S, Se or Te, hydrolyzing the reaction product, and treating the resulting compd. with an oxidizing agent such as air.

Coating compositions. Dunlop Rubber Co. Ltd., Alfred Niven, Edward A. Murphy and Evelyn W. Madge. Brit. 506,931, June 7, 1939. Matt surface finishes on articles are prepd. by coating them with a suspension obtained by forming a soln. of a resinous substance in a volatile solvent and adding to the soln. a further solvent in which the resinous substance is less sol. but which is miscible with the original solvent. In examples, coating compns. are obtained by dissolving (1) a vinyl resin in C_6H_6 or AcOEt and mixing the soln. with EtOH, and (2) shellac or colophony in alc. and mixing the soln. with H_2O.

Coating compositions. Alexander D. Macdonald (to B. B. Chemical Co. Ltd.). Brit. 507,637, June 19, 1939. The gelling tendency of liquid adhesives comprising solns. of plastic polymerized chloroprene in a solvent is diminished by the addn. of $NHEt_2$ and an ethanolamine. The chloroprene may be the product described in Brit. 468,435 (*C. A.* **32**, 833[9]) and the solvent may be C_6H_6, trichloroethylene, toluene, xylene or CCl_4. The compn. may also contain ZnO, MgO, S and an accelerator, e. g., a butyraldehyde-$PhNH_2$ condensation product. The product may be used in uniting outsoles to shoe bottoms.

Coating agents, priming and knifing compositions and putties. I. G. Farbenindustrie A.-G. Brit. 506,796, June 1, 1939. These contain as a binding agent an aq. dispersion of a polyvinyl compd., a resin soap and a chemically drying film-forming substance. Addnl. substances that may be added are resins, high mol. fatty acids, org. solvents, softening agents and pigments. Among examples, a putty that does not smear glass is made from an aq. dispersion of Me polyacrylate 31.8, H_2O 15.9, resin soap 15.9, a soln. of a condensation prod-

uct of phthalic acid, linoleic acid and glycerol in toluene or xylene 28, a resin oil obtained in the distn. of colophony 63.6, sperm oil fat acids 17.8 and whiting 827 parts.

Coating surfaces. Bakelite Ltd. Brit. 507,768, June 20, 1939. Articles are coated by immersing them successively in a mass of a heat-hardenable coating material, e. g., phenol-aldehyde resins, polyhydric alc.-polybasic acid resins, in liquid form and then, without intermediate exposure, in a mass of a heating liquid immiscible with the coating material. Molten alloys, molten wax, oils and other inert relatively nonvolatile org. liquids or melted solids may be used as heating liquids. App. is described.

Coating pipes, containers and agitating apparatus. Robert Wighton Moncrieff and Alfred Richmond. Brit. 507,488, June 14, 1939. App. for the storage, transport or treatment of liquids is given a surface resistant to aq. AcOH by forming on the surface a coating comprising an acetate of cellulose of Ac value about 58% or more. Where the surface is one to which the cellulose acetate does not readily adhere, e. g., of Fe or other metal, it is advantageous to apply 1 or more priming coats contg., e. g., nitrocellulose or a synthetic resin. In an example, a wooden vat is coated with a soln. of cellulose triacetate in $CHCl_3$.

Coated and impregnated paper suitable for table covers, building purposes, etc. Nicholas E. Oglesby. U. S. 2,173,129, Sept. 19. A process of treating a porous absorbent paper involves treating the paper with a water-resistant satg. medium which is flexible when set and selected from semidrying oils, drying oils and resins in the presence of above substantially 18% of water, the percentage of water being figured on the base paper wt., to incorporate therein solids to the extent of 50–150% of the base paper wt., drying the satd. paper and applying to the satd. paper a flexible, water-resistant finishing coating selected from paints, lacquers, varnishes and resins, whereby a durable waterproof composite article is formed which is not subject to cracking when bent and in which the bond between the finishing coat and the base is maintained when the article is subjected to flexing and bending in normal handling and use. U. S. 2,173,130 involves a flexible coated paper including a paper backing contg. an agent adapted to impart wet strength to the sheet and an agent adapted to soften the sheet, contg. semidrying oil present to the extent of 20–50% of the base paper wt. and a surface coating selected from paints, lacquers, varnishes and resins, the composite article being durable and water-resistant and not subject to cracking when bent, the bond between the surface coating and the treated base paper being of a nature to resist cracking and peeling when the article is subjected to flexing and bending in normal handling and use.

Zein films and coatings. Corn Products Refining Co. Brit. 507,807, June 21, 1939. Zein films, either cast or in the form of coatings, or other zein bodies, contg. a volatile solvent for zein are made resistant to H_2O and other liquids by being brought into contact, while in an incompletely dried but nontacky state, with steam at substantially atm. pressure. The solvent may be MeOH, EtOH, iso-PrOH, and a plasticizer, e. g., diethylene glycol, di-Bu tartrate, may be used. For increased hardness, CH_2O may be incorporated in the soln. The soln. may be used for lining paper containers, etc.

Impregnating compositions. Siemens & Halske A.-G. Brit. 507,855, June 21, 1939. An impregnating and sealing medium for elec. purposes is made by partially depolymerizing a hydrogenated "rubber hydrocarbon" (I) having a high degree of polymerization (I denoting a polymerization product of butadiene and its homologs, e. g., isoprene or dimethylbutadiene, or assocd. mixed polymerizates) by heating it, with exclusion of O from the atm., to such an extent that it is rendered readily sol., particularly in liquid benzine hydrocarbons or chlorinated hydrocarbons, and readily fusible without the use of a solvent and without decompn., and preferably to such an extent that the viscosity of a 10% soln. of the product is so low that the soln. is filterable through paper without the aid of pressure. Among examples, hydrogenated highly polymerized isoprene rubber in solid insol. form (obtained by heating isoprene with Na in a closed vessel and treating the product at 180–200° with H under 70 atm. pressure in the presence of a catalyst consisting of finely divided Ni) is heated, e. g., at 270°, in an autoclave contg. H at moderate pressure, e. g., 10 atm.; the product is dissolved in com. benzine, the soln. is passed over highly active Al_2O_3 under reduced pressure, liquid paraffin is added and the solvent is then removed by distn. under reduced pressure in several steps.

Press masses. Soc. pour l'ind. chim. à Bâle (Wilhelm Kraus, inventor). Ger. 679,873, Aug. 17, 1939 (Cl. 12o. 17.05). Hardenable masses are produced by condensing CH_2O, $(CH_2)_6N_4$ and urea or a mixt. of urea with other substances which react with CH_2O. The condensation takes place at a pH value of 3 with absorption of heat. Only sufficient $(CH_2)_6N_4$ is present to allow the reaction to remain acid at first, the whole being added subsequently. Examples are given.

Masses containing absorbents for the liquid constituents. N. V. W. A. Scholten's Aardappelmeelfabrieken. Brit. 506,929, June 7, 1939. A fibrous material obtained by washing potatoes until the remaining fibers contain 15% or less of starch and then drying and comminuting the fibers is used as an absorbent for the liquid constituent of plastic, explosive and other compns. comprising a liquid or liquefied constituent. Thus, the fibrous material may be used as a *substitute for cork meal in the production of linoleum, for wood meal* as a *filler in synthetic resin compns.* and *for diatomaceous earth* as an *absorbent for nitroglycerin*, etc., *in the manuf. of explosives.*

Bodying tung oil for use with fibrous material such as paper gaskets. Leander H. Hills (to Vellumoid Co.). U. S. 2,172,974, Sept. 12. Tung oil is heated to about 280° and then, before gellation occurs, cooled rapidly to below 175° in the absence of resin.

Compound sheet materials. Theophil Graser Brit. 508,210, June 28, 1939. Layers of wood veneer and fabric with an interposed foil of a cellulose deriv. are pressed together under heat to produce a reinforced veneer. A veneer may be provided with a triple layer of cellulose deriv., fabric and cellulose deriv. on both sides.

Plastic packing suitable for stuffing boxes. Frank E. Payne (to Crane Packing Co.). U. S. 2,173,744, Sept. 19. A packing is formed comprising an elongated compressible curved body contg. long fibers of heat-resistant materials such as asbestos with graphite and a binder of vulcanized rubber-like material, with a superficial reinforcing fabric.

Compressed powder magnetizable cores. Siemens & Halske A.-G. Brit. 506,878, June 6, 1939. A process for improving the permeability of compressed-powder cores produced by extrusion comprises adding to the mixt. of magnetic powder particles and binding agent, substances that improve the flowing capacity of the binding agent at the extrusion temp. so that a smaller proportion of binding agent is needed. Suitable substances are natural and artificial resins and salts of org. acids of high mol. wt., e. g., Ca stearate.

Transparent bodies. Patent-Treuhand Ges. für elektrische Glühlampen m. b. H. (John H. Partridge and Marcello Pirani, inventors). Ger. 679,916, Aug. 16, 1939 (Cl. 80*b*. 8.07). Glass-like bodies of m. p. above 1500° are made by sintering a powd. mixt. contg. at least 85% Al_2O_3 and SiO_2, at least 1% ThO_2 and at least 2% of BeO or MgO or both. The powder is sintered below the m. p.

Light-polarizing sheets. Edwin H. Land and Howard G. Rogers (to Polaroid Corp.). U. S. 2,173,304, Sept. 19. A transparent sheet which polarizes light by differential absorption of transmitted components comprises oriented long-chain mols. of an org. plastic such as dehydrated polyvinyl alc. some of which are dichroic and some of which are negligibly dichroic, the dichroic mols. being the product of an alteration within the sheet of the mol. structure of negligibly dichroic mols. and consisting only of atoms of elements present in the negligibly di-

chroic mols. Such alteration may be effected by heating while undergoing stretching.

Wax-like substances. I. G. Farbenindustrie A.-G. Brit. 507,244, June 13, 1939. These are produced by condensing aliphatic amines, having at least 1 hydrocarbon or hydroxylated hydrocarbon chain of 8 C atoms and at least 1 H atom attached to N, with cyclic polycarboxylic acids not capable of forming inner anhydrides, or functional derivs., e. g., halides or esters, thereof. Part of the amine may be replaced by an aliphatic polyamine, e. g., ethylenediamine, triethylenetetramine, or mixts. thereof. The materials may be condensed by heating together in the presence or not of high-boiling solvents or alkalies and with or without the addn. of oils, fats, waxes or the acids therefrom. Solvents for the products are turpentine and its substitutes, alcs., aromatic hydrocarbons, mineral-oil fractions, oils, fats, paraffin, ozocerite, ceresin and natural or synthetic waxes. The products may be purified, e. g., by active C, bleaching earths, sulfurous acid or H_2O_2; they may be used alone or in compns. for impregnating paper and textiles, and in wax compns., e. g., polishes and shoe creams. Among examples, terephthalic acid is condensed with octodecylamine (I), di-Me terephthalate is condensed with dodecylamine, and trimesic acid is condensed with I.

Antifreeze compositions. Wm. R. Canfield. U. S. 2,174,220, Sept. 26. A compn. having a freezing point below −45° contains NH_4Cl and Na_2CO_3 approx. 1 part each, a water-miscible polyhydric alc. such as glycerol 2–3 parts, and at least sufficient alkali metal hydroxide to neutralize acidity produced by other constituents, in an aq. soln.

Noncorrosive antifreeze liquid. Headlee Lamprey (to Carbide and Carbon Chemicals Corp.). U. S. 2,173,689, Sept. 19. An alc. such as EtOH or ethylene glycol is used with a corrosion inhibitor comprising a nitrite such as $NaNO_2$ and an alkali metal salt of maleic, crotonic, cinnamic or furyl acrylic acid, etc. Cf. *C. A.* **34**, 200².

Cooling medium for internal-combustion engines and heat-exchange systems. I. G. Farbenindustrie A.-G. Brit. 508,437, June 30, 1939. The medium consists of an aq. soln. contg. at least 10% of 1 or more neutral alkali metal fluorides with the addn. of 0.1–5% of the wt. of the fluoride(s) of an alkali metal silicate or chromate to lessen the corrosion, or comprise an aq. soln. of a fluoride of about 10% concn. and a monohydric alc. up to 50% by vol. of the soln., with or without the addn. of the silicate or chromate.

Sharpening files, rasps and the like with use of acid. Emanuele Zoppi. U. S. 2,173,218, Sept. 19. A method is employed which involves: (1) subjecting the articles to the degreasing action of a boiling 5% aq. NaOH soln.; (2) removing the articles from the NaOH soln. and rinsing them; (3) placing the articles in a bath consisting of about equal amounts of HCl and water, in which they are left for about 12 hrs. at normal temp.; (4) removing the articles from the acid bath and rinsing them; (5) placing the articles in a bath formed of HNO_3 of 42°Bé. 20 and water 80 parts in which they remain for 5–10 min. at normal temp.; (6) removing from the acid, rinsing and neutralizing any adhering acid in a milk of lime bath.

Apparatus for applying cellulose acetate solution, etc., to strands of material such as textile-covered wire. Waldemar C. Ewaldson and Heinz Kress (to Western Elec. Co.). U. S. 2,172,837, Sept. 12. Various structural, mech. and operative details.

Permanent waving of hair. Myles W. Fletcher (to Utility Sales Corp.). U. S. 2,173,297, Sept. 19. A mixt. which may comprise a chlorate such as $KClO_3$ about 3 and a powd. metal such as Al of a fineness of about 30 mesh about 1 and a powd. metal oxide such as Cu oxide about 1 part is used with a heat-producing soln. of NH_4Cl, etc.

Heat-generating materials for use in waving hair. Abraham R. Goldfarb and Edwin B. Michaels (to Lawrence R. Bruce, Inc.). U. S. 2,173,683, Sept. 19. A package for use in waving hair comprises a container of paper or cloth holding a filter of Al or other metal such as Zn or Mg and a mercurous salt such as HgCl which generate heat when moistened with a water-sol. NH_4 compd. Various examples are given.

Printing. Gerhard G. W. Madaus, Friedemund J. N. Madaus and Johannes M. T. Madaus (trading as Dr. Madaus & Co.). Brit. 508,166, June 27, 1939. Freshly printed matter is sprayed with a soln. in H_2O and alc. of a substance chemically related to the cellulose of the paper, e. g., hydrophilic colloids such as methylcellulose or other cellulose ethers. The soln. is obtained by swelling up the cellulose ether in H_2O, homogenizing the soln. and mixing it with alc. Thus, a soln. contg. 200 g. methylcellulose dissolved in 10 kg. H_2O, to which 2 kg. alc. is added, is made up and this soln. dild. before use.

Covering for printing rollers. Gustave Auvray. U. S. 2,172,491, Sept. 12. A composition for the manuf. of coverings for printing rollers, etc., consists essentially of an intimate admixt. of about 100 parts of satd. aq. $MgCl_2$, 95 parts of com. wheat starch having a water content of about 0.5–9%, the starch having had an original water content of about 13%; $MgCl_2$ in an amt. corresponding to the difference in wt. between the first-mentioned water content of the starch and its original water content; and 2 to 10 parts of a slightly drying oil.

Inking rollers for lithographic printing machines. Coates Brothers & Co. Ltd. and Lancelot Coates. Brit. 508,239, June 28, 1939. The rollers comprise a steel or other metal body having a surface of Cu that is not liable to be rendered ink repellent by the etches or gum arabic used in the printing. The rollers preferably comprise a Cu-plated steel roller that has been cleaned with a soln. of 1 in alc., provided with a film of bituminous wash-out and finally washed with paraffin or other ink solvent.

Hectograph roll or blanket. Wm. Hoskins, Jr. (to Ditto, Inc.). U. S. 2,172,873, Sept. 12. A duplicating sheet comprises a flexible backing such as paper or cloth, a layer of hectograph compn. applied to the backing and an adhesive compn. contg. an adsorbent inorg. colloidal material such as bentonite securing the hectograph compn. to the backing.

Electrotype matrices. Herbert Libberton (to Tenak Products Co.). U. S. 2,172,563, Sept. 12. A method of making a molded tablet for use as an electrotype matrix consists in applying a layer of plastic material upon an Al sheet of predetd. stiffness and then forming the tablet throughout its entire thickness, including the Al sheet, to the general contour of a master pattern while the specific configuration of the pattern is impressed upon a surface of the layer of plastic material. U. S. 2,172,564 relates to a moldable tablet for use in the prepn. of electrotype, comprising a sheet of Al of predetd. stiffness, a binding film on a surface of the sheet, a layer of moldable material secured to the sheet by the binding film and a parting layer in the exposed surface of the moldable material.

Inhibiting screw-thread seizure. Charles E. S. Place (to Clare L. Brackett). U. S. 2,173,003, Sept. 12. A covering coating of graphite is rolled into the thread surfaces. U. S. 2,173,004 also relates to the use of a thread-surface coating of a stable, nonoxidizing, heat-resistant material such as graphite.

Lightning arrester. Syuhei Huzitaka and Tositaro Takenouti. U. S. 2,173,625, Sept. 19. Plates of Cu covered with Cu sulfide are used in direct and intimate contact with plates of Al.

Air-permeable soles for footwear. Karl Mayer and Richard Haupt. Brit. 508,824, July 6, 1939. These comprise a basic material of felt, thick fabric, air-permeable paper, etc., uniformly impregnated with a soln. of an artificial resin and dried without hardening of the resin so as to preserve pliability. A nonhardening resin, e. g., polyvinyl acetate, is preferably used. A small quantity of nitrocellulose may be admixed with the impregnating soln.; also softening agents, e. g., tritolyl phosphate, or fillers, e. g., chalk.

Stiffening fabrics such as those for toes of shoes. Bjorn Andersen (to Celluloid Corp.). U. S. 2,173,821, Sept. 26. In the use of a stiffening material such as muslin contg. cellulose acetate, there is applied to an article such

as a box toe blank comprising an outer layer such as leather and the stiffening material a softening soln. contg. a solvent for the cellulose deriv. such as acetone, and an alkali such as NH_4OH which has a softening action on the outer layer, and the treated article is shaped and dried.

Stiffening sheet material such as that for box toes of shoes. Roy S. Ritchie (to Celluloid Corp.). U. S. 2,173,861, Sept. 26. A process of mfg. a sheet material capable of being made adhesive, flaccid, shaped and stiffened comprises prepg. a soln. of a cellulose deriv. such as cellulose acetate in a low-boiling solvent such as acetone, impregnating a base sheet material such as muslin with the soln. and then speedily pptg. the cellulose deriv. by applying a heated vapor of a pptg. agent such as steam to the impregnated sheet material.

Stiffening material for box toes of shoes, etc. Ernest Schweizer (to Celluloid Corp.). U. S. 2,174,170, Sept. 26. An arrangement of app. is described, and a method of forming a stiffening material comprising a base such as a suitable fabric impregnated with a cellulose deriv. compn. (such as one of cellulose acetate) which involves impregnating the base with a liquid medium comprising the deriv. of cellulose, a volatile solvent for the deriv. of cellulose and water, and applying steam to the impregnated material under such conditions that at least the bulk of the volatile solvent is removed while the water content of the impregnated material is increased whereby the deriv. of cellulose is pptd. on the base in a porous form, all steps being performed in substantial absence of air.

Insect-repellent materials. Albert Smith. Brit. 508,163, June 27, 1939. A prepn. for application to stockings, etc., comprises sucrose octoacetate and an insect repellent, e. g., oil of citronella, with or without menthol and thymol, and in some cases with the addn. of quinine, which may also replace the oil of citronella. The ingredients are made up with a base of soap flakes when for use as an aq. wash, or with spirit, e. g., methylated spirit, when intended as a spray.

Compositions for destroying slugs and other pests. Boot's Pure Drug Co. Ltd., Arthur D. Powell, James C. E. Tait and The Right Honourable Lord Wolmer. Brit. 508,125, June 27, 1939. The compns. are produced by forming discrete pieces of a paste contg. metaldehyde (I) and a fatty vehicle, e. g., lard, and baking the same at a temp. low enough to avoid substantial volatilization of the I, e. g., at about 130°F. The paste may also contain a material such as bran or "fourths," a mucilageous substance, e. g., flour mucilage, and a substance that liberates gas during the baking, e. g., NH_4 carbonate.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

Safeguards for ground-water supplies. Leslie K. Sherman. *J. New Engl. Water Works Assoc.* **53**, 299–306 (1939).—Location, construction and protection of distribution are all important. Analytical control is necessary. D. K. French

Heavy water content of the Manila water supply and of the artesian water of the University of the Philippines. Antonia F. Castañeda and Amando Clemente. *Univ. Philippines Nat. and Applied Sci. Bull.* **7**, 19–23(1939).—By means of d. detns. on concentrates obtained by electrolysis, and by taking d_{15}^{25} for D_2O as 1.1079 and for H_2O as 0.997044, the D_2O contents of Manila tap water and Univ. Philippines artesian water were 52.1 and 51.5 cc. per million cc., resp. D_2O cannot be quantitatively concd. in H_2O by mere open boiling of the latter. G. A.

Rapid sand filtration plant for Willimantic, Connecticut. Roland F. Kittredge. *J. New Engl. Water Works Assoc.* **53**, 328–36(1939).—River water, soft, highly colored and generally unsatisfactory, is used. It is aerated. Coagulant and, when necessary, alkali are added. Cl is added before the conditioning tank. The water is chlorinated. The settling basins and filters are described. The pH is held around 8.5 by lime. Results are considered good. D. K. French

Some popular misconceptions concerning the function, value and significance of water analysis. Charles D. Howard. *J. New Engl. Water Works Assoc.* **53**, 362–71 (1939).—The results of a water analysis must be interpreted in connection with many other factors—geological, historical, industrial and environmental, and definite conclusions cannot always be drawn from the analytical results. Neg. results cannot be depended upon as indications of the absence of danger. The relative value of the different kinds of analysis is discussed. D. K. French

Lime for water-works use. J. G. Thompson. *J. New Engl. Water Works Assoc.* **53**, 253–60(1939).—Following a summary of the A. S. T. M. specifications for quicklime and hydrated lime for water treatment, T. follows briefly the course of the limestone from the quarry to the finished product. D. K. French

Copper sulfate for water-works use. E. Fitzpatrick. *J. New Engl. Water Works Assoc.* **53**, 261–4(1939).—After a brief historical mention, "shot copper" from the smelters is followed through the plant to the production of the finished copper sulfate. D. K. French

Activated carbon—manufacture and specifications. E. A. Sigworth. *J. New Engl. Water Works Assoc.* **53**, 265–70(1939).—After a summary of the materials used and the A. W. W. A. specifications, there is a brief discussion of the threshold odor test. D. K. French

Methods of deoiling feed water. F. J. Matthews. *Eng. & Boiler House Rev.* **53**, 220–2, 224(1939).—A review. George Ayers

Cyanide compounds in water and sewage. Martin Strell. *Gesundh.-Ing.* **62**, 546–50(1939).—The sources of wastes contg. $(CN)_2$, HCN and its salts, CNS and complex cyanides are discussed together with methods of estn. Cyanides can be removed by formation of ferrocyanides or aeration from acid solns. Foster Dee Snell

Modern trends in sewage treatment. J. B. Baty. *Can. Engr.* **77**, No. 17, 24, 26, 28, 30, 32(1939).—Chem. pptn. has been revived in the last 7 years, the installations of magnetic filters are increasing and Cl is now being used to facilitate removal of grease. Elutriation of sludge, particularly digested sludge, has increased the efficiency of the vacuum filter and reduced operating costs. The use of mech. equipment and incineration is increasing. Ann Nicholson Hird

Trends in primary sewage treatment. Douglas L. McLean. *Can. Engr.* **77**, No. 17, 18, 20, 22, 32(1939).—Results obtained at the Greater Winnipeg plant. Ann Nicholson Hird

Interpretation of sewage tests. A. E. Berry and A. V. DeLaporte. *Can. Engr.* **77**, No. 17, 34, 36, 38, 40, 42, 44 (1939).—The technique of sampling and the chem. and bacteriol. analyses in common use are discussed with their sources of error. Ann Nicholson Hird

Activation of sludge. S. Mihaćloff. *J. pharm. chim.* **30**, 13–16(1939).—By passing air into 3 samples of sewage of different origins, it took about 30 hrs. at the start to nitrify 10 mg. NH_3 per l.; after 15–20 days, nitrification of 10 mg. NH_3 per l. took place within 1–2 hrs. There was also pptn. of $CaCO_3$ which adsorbed suspended and dissolved org. matter, forming filaments which contributed to rapid pptn. Only when sewage is sufficiently rich in $CaCO_3$ as bicarbonate, will nitrous and nitric enzymes present grow and multiply in abundance; i. e., the sludge is then activated. Soil humus and decaying leaves did not clarify sewage, as they are relatively poor in org. matter. In M.'s expts., nitrous enzymes oxidized NH_3 to HNO_2; this was oxidized to HNO_3 by the nitric enzyme; the latter cannot oxidize NH_3 at all. S. W.

Water pollution. Robert S. Weston. *Ind. Eng. Chem.* **31**, 1311–15(1939).—Use rather than abuse of

streams' capacity for self-purification indicates treatment to maintain 4 p. p. m. of dissolved O in streams used for water supply and 2 p. p. m. in others. 33 references. Foster Dee Snell

Pollution of an industrial ground-water supply by organic waste products. Gordon M. Fair. *J. New Engl. Water Works Assoc.* **53**, 316–17 (1939).—After several years' satisfactory operation org. deposits and *Crenothrix* appeared. Dumping of wastes, largely spent wort, upon low land was found to be responsible. D. K. French

Nonorganic pollution of well supplies. E. Sherman Chase. *J. New Engl. Water Works Assoc.* **53**, 318–27 (1939).—Several cases of pollution from gas or gas mains, phenols and coal-tar products are described. D. K. F.

Possible pollution of private water supplies. Ernest J. Sullivan. *J. New Engl. Water Works Assoc.* **53**, 309–15 (1939).—Different types of wells are described and then numerous typical sources of pollution are cited and their effect on the wells is described. D. K. French

Atmospheric pollution. Philip Drinker. *Ind. Eng. Chem.* **31**, 1316–20 (1939).—Atm. pollution by gas, liquid droplets or solid particles may be harmful to animal and vegetable life and to machinery, cause a nuisance or produce an explosive mixt. It may be man-made or a natural phenomenon. The types and their abatement are discussed particularly in terms of SO_2, H_2S, CS_2, CO, mists and fogs, dust and fumes. Foster Dee Snell

Waste problems of a chemical company. L. F. Harlow. *Ind. Eng. Chem.* **31**, 1346–9 (1939).—At the Dow plant about 24,000 bbls. per day of brine is disposed of by periodic discharge into a river at high water flow after notification of nearby manufacturers and water plants. Storage for 2 years' excess is provided. Concn. in the stream at discharge is kept below 5000 p. p. m. of NaCl. Pumping into a sand stratum was accompanied by surface seepage. Scrubbing water contg. taste and odor offenders is cooled and clarified in a 65-acre pond and recycled. Wastes contg. 13 30 p. p. m. of phenols were first inoculated with sewage bacteria, later with soil bacteria. Fed to trickling slag filters at 16 million gals./acre/day this is reduced to 0.4–3.0 p. p. m. The feed must be at 70°F. or higher to get this rate; below 50°F. there is practically no effect. Passage through a 31-acre detention pond further reduces it below 0.05 p. p. m. Effluents depositing sediments flow through 42 acres of shallow ponds. Atm. pollution is avoided by scrubbing vent gases with acid, alkali or charcoal, often at a profit. Foster Dee Snell

Utilization of industrial wastes. H. E. Howe and F. J. Van Antwerpen. *Ind. Eng. Chem.* **31**, 1323–30 (1939).—A great no. of cases of waste and by-product utilization from pulp and paper, wood, metal pickling, minerals and metals, petroleum and agriculture are described. Utilization of gases, dusts and sewage are followed by examples from miscellaneous industries. Foster Dee Snell

Biological processes for treating waste. A. M. Buswell. *Ind. Eng. Chem.* **31**, 1349–51 (1939).—All types of org. waste are amenable to biol. treatment. Aerobic fermentation yields CO_2, H_2O and a protoplasmic solid. Anaerobic treatment yields CO_2, CH_4 and a humus-like solid. Aerobic processes treat dil. liquors, often by recirculation, on rock beds or in tanks with air diffusers. Anaerobic treatment, which is normally less expensive, treats waste down to 1% concn. in simple covered tanks. F. D. S.

Boron [amt. in wells and springs] in horticulture (Overholser, *et al.*) **15**. App. for taking samples of water and for transporting the app. in a sterile condition (Brit. pat. 508,585) **1**. Clarifying waste water (Ger. pat. 679,906) **23**.

Apparatus for treating water with reagents. Frank B. Barclay and Henry E. May, Jr. (to Dearborn Chemical Co.). U. S. 2,172,951, Sept. 12. Various details of app. suitable for use with a locomotive tender tank.

Apparatus for agitating, aerating, mixing and purifying water or other liquids or gases. Gilbert C. Unger, Jr. U. S. 2,174,147, Sept. 26. Various details of an app. having an upwardly acting propeller and a downwardly acting fan mounted on the same vertical shaft.

Electrical treatment of water. Wm. A. Beatty. Brit. 507,052, June 5, 1939. In a method of treating H_2O flowing through a pipe for the prevention of scale formation as described in Brit. 450,594 (*C. A.* **31**, 194[8]), the c. d. is automatically maintained at an optimum value dependent on the rate of flow, within the limits prescribed in 450,594. App. is described.

Aeration apparatus for the activated-sludge sewage-treatment process. James D. Walker (to American Well Works). U. S. 2,172,646, Sept. 12. Various structural and operative details.

Septic tank sludge ejector. Duer H. Buckley (to J. W. Swanson). U. S. 2,173,932, Sept. 26. Various details of app. provided with a sludge pump.

Removing phenol from waste water. Hydrierwerk Scholven A.-G. (Wilhelm Urban, inventor). Ger. 679,974, Aug. 18, 1939 (Cl. 12*q*. 14.01). PhOH is removed from waste water from hydrogenation processes by using the PhOH-rich water as the washing liquid in the high-pressure washing system at the point where the vaporized hydrogenated oil has been condensed by cooling. The oil then removes the phenol.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

M. S. ANDERSON AND K. D. JACOB

Report of the Imperial Agricultural Chemist. B. Viswa Nath. *Sci. Repts. Imp. Agr. Research Inst., New Delhi* **1937–38**, 85–104; cf. *C. A.* **32**, 4265[5], 4206[1].—*Soils.*—The black soils of India, although differing in their geol. origin, are characterized by their high clay content with high values for Al silicates. Under the influence of large diurnal differences in temp. and high satn. deficit, they have developed profiles with high SiO_2:Al_2O_3 ratios, high base-exchange capacity and relatively high exchangeable Na and Mg in lower depths. The red, brown and laterite soils, irrespective of their origin, are characterized by low clay content, low exchange capacity and lower SiO_2:Al_2O_3 ratios. The pinkish soils of the Indus basins and valleys and their tributaries, which are probably derived from granitic syenites or other massive rocks yielding syenites during the early stages of decompn., show alky. to a greater or less extent. Their profiles indicate varying degrees of decompn., setting free alkali, and Fe and Al moving into lower layers. In arid and semiarid regions Ca constitutes 70–80% of the total exchangeable bases while Mg, Na and K together vary between 5 and 15%. In regions with high rainfall the exchangeable Ca is lower at the surface than in deeper layers. The black soils have the highest total exchange capacities, the red soils intermediate and the laterites the lowest values. Soils that in 6 weeks fail to nitrify more than 25% of the N added as oil-free mustard cake occur in a strip running east to west, the entire width of the northern strip of Peninsular India, and comprise practically all types of soils and climatic regions. The defective nitrification cannot be correlated with any of the soil characteristics so far detd. *Fixation of atm. N by cereal crops.*—Expts. with maize and wheat, grown in ignited and washed sand in an atm. free from combined N, indicated that these cereals are able to fix atm. N to the extent of about 40–57% of the total N present in the crop. *Effect of org. manures and fertilizers on the nutritive quality of wheat.*—Grain from plants fertilized only with cattle manure contained more total protein, had a higher net protein value, a decidedly higher digestibility coeff. and a slightly higher biol. value than did that from plants receiving only mineral fertilizers or no fertilizer. In all cases the values obtained

as a box toe blank comprising an outer layer such as leather and the stiffening material a softening soln. contg. a solvent for the cellulose deriv. such as acetone, and an alkali such as NH_4OH which has a softening action on the outer layer, and the treated article is shaped and dried.

Stiffening sheet material such as that for box toes of shoes. Roy S. Ritchie (to Celluloid Corp.). U. S. 2,173,861, Sept. 26. A process of mfg. a sheet material capable of being made adhesive, flaccid, shaped and stiffened comprises prepg. a soln. of a cellulose deriv. such as cellulose acetate in a low-boiling solvent such as acetone, impregnating a base sheet material such as muslin with the soln. and then speedily pptg. the cellulose deriv. by applying a heated vapor of a pptg. agent such as steam to the impregnated sheet material.

Stiffening material for box toes of shoes, etc. Ernest Schweizer (to Celluloid Corp.). U. S. 2,174,170, Sept. 26. An arrangement of app. is described, and a method of forming a stiffening material comprising a base such as a suitable fabric impregnated with a cellulose deriv. compn. (such as one of cellulose acetate) which involves impregnating the base with a liquid medium comprising the deriv. of cellulose, a volatile solvent for the deriv. of cellulose and water, and applying steam to the impregnated material under such conditions that at least the bulk of the volatile solvent is removed while the water content of the impregnated material is increased whereby the deriv. of cellulose is pptd. on the base in a porous form, all steps being performed in substantial absence of air.

Insect-repellent materials. Albert Smith. Brit. 508,163, June 27, 1939. A prepn. for application to stockings, etc., comprises sucrose octoacetate and an insect repellent, e. g., oil of citronella, with or without menthol and thymol, and in some cases with the addn. of quinine, which may also replace the oil of citronella. The ingredients are made up with a base of soap flakes when for use as an aq. wash, or with spirit, e. g., methylated spirit, when intended as a spray.

Compositions for destroying slugs and other pests. Boot's Pure Drug Co. Ltd., Arthur D. Powell, James C. E. Tait and The Right Honourable Lord Wolmer. Brit. 508,125, June 27, 1939. The compns. are produced by forming discrete pieces of a paste contg. metaldehyde (I) and a fatty vehicle, e. g., lard, and baking the same at a temp. low enough to avoid substantial volatilization of the I, e. g., at about 130°F. The paste may also contain a material such as bran or "fourths," a mucilageous substance, e. g., flour mucilage, and a substance that liberates gas during the baking, e. g., NH_4 carbonate.

In regions with high rainfall the exchangeable Ca is lower at the surface than in deeper layers. The black soils have the highest total exchange capacities, the red soils intermediate and the laterites the lowest values. Soils that in 6 weeks fail to nitrify more than 25% of the N added as oil-free mustard cake occur in a strip running east to west, the entire width of the northern strip of Peninsular India, and comprise practically all types of soils and climatic regions. The defective nitrification cannot be correlated with any of the soil characteristics so far detd. *Fixation of atm. N by cereal crops.*—Expts. with maize and wheat, grown in ignited and washed sand in an atm. free from combined N, indicated that these cereals are able to fix atm. N to the extent of about 40–57% of the total N present in the crop. *Effect of org. manures and fertilizers on the nutritive quality of wheat.*—Grain from plants fertilized only with cattle manure contained more total protein, had a higher net protein value, a decidedly higher digestibility coeff. and a slightly higher biol. value than did that from plants receiving only mineral fertilizers or no fertilizer. In all cases the values obtained

on grain from unfertilized plants were higher than those on grain from plants receiving mineral fertilizers. *Anthocyanin pigments in the rind of sugar canes.* The pigments isolated from the rind of colored canes, such as Purple Mauritius, Red Mauritius and Badila (Fiji B), appeared to be mostly monomethyl derivs. of *delphenidine*. The coloring matters were successfully eliminated in sulfitation sugar factories by heavy liming and then using $Al(OH)_3$. K. D. Jacob

Colloid chemical investigation on the soils near the Osaka Harbor. I. Test on the solidity. Noriyosi Morita and Tosizo Titani. *J. Chem. Soc. Japan* **60**, 826–30(1939).—The results of the compression test of the soils collected from various parts and various depths of the Osaka Harbor are given. It has been shown that the soil from a certain depth shows min. compressibility. **II. Water content, velocity of drying and contraction ratio.** *Ibid.* 831–4.—The results of the detn. of water content, velocity of drying and contraction ratio are given. T. K.

The quantity, distribution and composition of the organic matter and available nitrogen in Egyptian soils. David S. Gracie and Fahmy Khalil. *Ministry Agr. Egypt, Tech. Sci. Service, Bull.* 222, 42 pp.(1939).—Samples taken from 24 profiles at depths of 0–25, 25–50, 50–75 and 75–100 cm. averaged 0.84, 0.64, 0.57 and 0.53% org. C and 0.074, 0.053, 0.044 and 0.039% total N, resp. The surface soils, to a depth of approx. 10 cm., averaged 0.95% org. C and 0.086% total N. The org. matter consisted principally of hydrolyzable protein, resistant protein and lignin. The increase in the C:N ratio with depth was assocd. with an increase in the proportion of lignin and a decrease in the hydrolyzable and resistant protein. The C:N ratios and the total amts. of org. matter in the soils as originally laid down were likely the same in all layers, but the C:N ratio in the surface has become reduced through the accumulation of residues high in protein. In different years and with various crops the sum of the nitrate N and NH_4 N in the surface soils ranged from 18.6 to 27.4 p. p. m. and the hydrolyzable N (N converted into NH_3 by heating 50 g. soil with 500 cc. 0.1 *N* H_2SO_4 in an autoclave under 1 atm. pressure for 0.5 hr.) from 15.1 to 20.3 p. p. m. The hydrolyzable N and the sum of the nitrate N and NH_4 N both decreased with increase in depth and the ratio of nitrate N + NH_4 N to hydrolyzable N also decreased. The total available N (nitrate N + NH_4 N + hydrolyzable N) in the soil increased during the period of drying between crops, but the beneficial effect of the drying period on the accumulation of available N tended to be lost by irrigation too soon before the succeeding crop was planted, apparently as a result of the assimilation of N by the soil microorganisms. Expts. with wheat showed that the nitrate and NH_4 N of the soil are effective mainly on the straw and that the hydrolyzable N acts principally on the grain. Owing to variations in climatic conditions, there was a significant difference in the efficiency of nitrate and NH_4 N for straw production in different years. There were indications that all the available N down to a depth of 1 m. is of importance to the wheat plant. Twenty-four references. K. D. Jacob

Organic matter in orchard soils. Geo. H. Dickson. *Ann. Rept. Nova Scotia Fruit Growers' Assoc.* 75, 108–9, 111–13, 115(1938).—Over a period of 8 yrs., apple trees were mulched with green alfalfa hay twice each yr. with supplemental addns. of old hay from time to time. At the end of this time the 0–6, 6–12 and 12–18-in. depths of soils under mulch contained readily available K 50, 20, 20 p. p. m., nitrate 313, 136.5, 95 p. p. m. and water 10.9, 8.8, 4.9%, resp. The soil between the trees contained readily available K 15, 5, 5 p. p. m., nitrate 54.6, 27.8, 21.7 p. p. m. and water 5.7, 6.8, 4.5%, resp. K. D. J.

The decomposition of organic matter in soils at different initial pH. R. S. Dyal, F. B. Smith and R. V. Allison. *J. Am. Soc. Agron.* **31**, 841–50(1939).—A study was made of the decompn. of green crotalaria and green natal grass harvested at 2 different stages of growth in Norfolk loamy fine sand of varying degrees of acidity from pH 3.71 to 7.05. All plant materials decompd. more rapidly and more completely in soils at pH 5.94 to 7.05 than at pH 3.71 to 4.59. The detrimental effect of acidity on decompn. was more pronounced in soils treated with natal grass than in soils treated with crotalaria. The acidity of the soils treated with crotalaria was decreased markedly in the soils at low pH in the beginning of the expt. The addn. of N as KNO_3 to the natal grass-treated soils in an amt. sufficient to bring the total N content of these soils to that of crotalaria-treated soils did not increase the decompn. of the natal grass. Decreased nitrification in the soils at pH 3.71, 4.26 and 4.59 was undoubtedly brought about by the microörganisms utilizing the NH_3 in the decompn. of the carbonaceous materials and also partly by the detrimental effect of the increased acidity on the nitrifying bacteria. A deficiency of available Ca in the strongly acid soils could possibly have caused this decreased nitrification observed in the soils at low pH. Plant materials contg. large percentages of the hemicellulose, cellulose and lignin fractions decompd. more slowly than those contg. the smaller percentages of these constituents. J. R. A.

Some Nigerian cacao soils. F. Hardy. *Ann. Rept. Cacao Research* 8, 23–6(1938)(Pub., 1939).—The characteristics of 6 soil types and subtypes are described. Summarized results on surface 6-in. samples, representing 19 profiles, showed org. matter 0.9–4.9%, C:N ratio 9.1–15.2, pH 4.1–7.0, available P_2O_5 (Truog test) 2–1387 p. p. m. and available K_2O (extractable by 0.5 *N* AcOH) 38–472 p. p. m. K. D. Jacob

Soil demands of Kalanchoe blossfeldiana (var. selecta). F. Vogel, C. Biermann, R. v. Hösslin and K. Schneble. *Gartenbauwiss.* **13**, 327–50(1939).—Various soil and compost mixts. were tested in pot expts. to det. their effect on the growth and keeping qualities of *Kalanchoe blossfeldiana*. The optimum range of soil reaction for growth was between pH/KCl 5.5 and 7.0. A mixt. of equal amts. of strongly acid heath soil and compost produced the strongest growth. The compost alone when brought to the same pH with H_2SO_4 or $CaCO_3$ was less favorable. $CaCO_3$ had a slight beneficial effect in the pure compost but acted oppositely in the heath soil. The addn. of crude peat mull or loam to leaf soil caused 1 or more of the following: weak vegetative development, delayed blooming and poor keeping qualities of the flowers. More favorable results were obtained with a mixt. of the soils or the replacing of the peat mull with various kinds of peat humus or manure. Peat humus prepd. with org. fertilizers was better than that with mineral fertilizers. The reaction of the employed soil mixts. varied between pH/KCl 7.18 and 5.42, the total acidity between 0 and 2.45 and the $CaCO_3$ content between 0.02 and 0.70%. C. K. H.

The reciprocal relations between some soil properties in the light of a simple calculation of correlation. Vladimir Gossl. *Bodenkunde u. Pflanzenernahr.* **14**, 247–56(1939).—A math. study of the relation between certain phys. properties, e. g., pore vol. and H_2O capacity, with percentage of dispersable constituents and available K_2O of a no. of soils indicated no close correlation. Conclusion: Soils cannot be characterized by any "single value." Fourteen references. C. J. Schollenberger

Experimental investigation on the penetration of radiant energy into the soil. Franz Frischmann. *Bodenkunde u. Pflanzenernahr.* **14**, 257–90(1939).—Photoelec. measurements indicate that the energy of light of any wave length does not penetrate more than 8 mm. into soil, except as heat. C. J. Schollenberger

The relation of soil reaction, erosion and aggregation of silt and clay in Clarksville loam. H. T. Rogers. *J. Am. Soc. Agron.* **31**, 915–23(1939).—Increasing sheet erosion was observed on Clarksville loam as the acidity increased from pH 7.41 to pH 4.46, irrespective of $Al_2(SO_4)_3$ or other treatment. A highly significant neg. correlation was found between aggregation and H-ion concn. Increasing quantities of sol. Al were accompanied by decreasing quantities of silt and clay aggregated into units larger than silt size. No significant relationship existed between total org. matter and degree of aggregation or observed erodibility. The addn. of ground limestone to Clarksville loam up to the quantity required to produce a

neutral reaction definitely improved the phys. condition of the soil and its resistance to erosion. J. R. Adams

The oxidation-reduction potential of alkaline calcareous soils in relation to puddling and organic matter decomposition. T. F. Buehrer, W. P. Martin and R. Q. Parks. *J. Am. Soc. Agron.* **31**, 903–14(1939).—The Eh-pH relationship in arid alk. soils could be more satisfactorily studied by making use of the pH change due to simple diln. with water than by adding acid or alk. solns. Puddling causes a marked decrease in the reduction-oxidation potential, particularly when the soil has been treated with alfalfa. A sharp initial drop in the potential occurs in both puddled and unpuddled soils that have been treated with alfalfa. Measurements of reduction-oxidation potential made in an atm. of N and O, resp., give evidence of the existence of an oxygen potential, inasmuch as the reduction-oxidation potential drops sharply when N is bubbled through and increases in the presence of O. J. R. Adams

Some problems connected with fertilization of alkali soils. W. T. McGeorge. *Calif. Citrograph* **24**, 380, 424 (1939).—The effect of alky. in the alk. calcareous soils of Arizona is not one of direct toxicity from Na_2CO_3 or hydroxyl-ion concn. but rather one in which the nutritional balance and absorptive process of the plant are seriously disturbed. The continuous use of acidulated fertilizers will promote a normally balanced nutrition of both field and orchard crops on these soils. J. R. Adams

Availability, fixation and liberation of potassium in high-lime soils. Hubert Allaway and W. H. Pierre. *J. Am. Soc. Agron.* **31**, 940–53(1939).—A study of the high-lime soils of north central Iowa shows that the productive soil in any given field contains from 31 to over 700% more exchangeable K than the unproductive soil. The unproductive soil is generally higher in $CaCO_3$ and, in every case, shows a greater K-fixing power than the productive soil. Eight of the 12 productive soils contain less than 15% $CaCO_3$ in the surface 6 in. In 4 out of 5 fields the productive soils show a more rapid liberation of nonexchangeable K, although the differences are relatively small. Thus, differences in the amts. of exchangeable K present may account, at least in part, for the differences in plant growth between unproductive high-lime soils and adjacent soils which support normal plant growth. The high-lime soils of Iowa apparently require more exchangeable K to support good crop growth than do the normally acid soils of central U. S. Excessively high concns. of $CaCO_3$ and $Ca(HCO_3)_2$ may contribute to the low productivity of these soils. The study indicates that soils of north central Iowa which contain more than 15% $CaCO_3$ and less than 175 lb. of exchangeable K per acre will likely show signs of extreme K deficiency and respond markedly to K fertilization. The high K-fixing power of unproductive high-lime soils may be responsible for the relatively low amts. of exchangeable K in these soils which no doubt explains the small residual effects obtained from applications of K fertilizers. J. R. Adams

The polarographic estimation of alkalies and calcium in the electro-ultrafiltrate from forest soils poor in bases. L. Mainzhausen. *Bodenkunde u. Pflanzenernahr.* **14**, 290–6 (1939).—The app. and procedure of Heyrovský and Shikata (*C. A.* **19**, 2905) are recommended for rapidly detg. the minute quantities of Na, K and Ca sometimes occurring, and more concd. solns. can be dild. Six references. C. J. Schollenberger

The fixation and release of applied potash on three coastal plain soils. J. M. Blume and E. R. Purvis. *J. Am. Soc. Agron.* **31**, 857–68(1939).—The amt. of K fixed, when applied at the rates of 0, 50, 100, 200, 400, 800 and 1600 lb. of K_2O per acre to 3 different soils, varied greatly from month to month indicating that the properties of a soil which affect fixation are dynamic in nature. Under controlled conditions, the amt. of K held in the replaceable state remained const. over a 5-month period in Portsmouth and Elkton soils, while the fixed fraction varied greatly, the variation being reflected in the H_2O-sol. fraction. Monthly removal of the H_2O-sol. K by leaching greatly reduced the replaceable and fixed fractions of K in all 3 soils tested. J. R. Adams

Heat conductivity as an index of soil moisture. Byron Shaw and L. D. Baver. *J. Am. Soc. Agron.* **31**, 886–91 (1939).—A diagram and description are given of an adaptation of the Wheatstone bridge for measuring the changes in heat cond. of a soil at varying moisture contents. Heat cond. gives a reliable index of the moisture content of the soil. Changes in salt concn. of the soil soln. do not materially affect the heat cond. of the soil. J. R. Adams

A soil-moisture tensiometer with a compact manometer. L. A. Richards and R. W. Pearson. *J. Am. Soc. Agron.* **31**, 986–9(1939).—An illustration and the method of manipulation are given for a compact form of manometer, which can be used on tensiometers installed in greenhouse pots, to aid in detg. when water is needed and the amt. to be applied. J. R. Adams

The influence of soiling and silage crops in the rotation upon the moisture supply of the soil and yields of main crops. K. Opitz and E. Tamm. *Bodenkunde u. Pflanzenernahr.* **15**, 1–46(1939).—Extensive plot tests with frequent detns. of the H_2O content of the soil indicate that green crops harvested by late fall do not seriously deplete the soil moisture for the next crop, but if growth continues into the next spring, yields of the main crop following are likely to be less in seasons of normal rainfall. The N supplied by residues from a leguminous intercrop may overcome the adverse effect; a rye-vetch mixt. is one of the best for the purpose, under German conditions. C. J. Schollenberger

Queensland Cotton Research Station, Biloela. Progress report for the season 1937–38. [Effect of cropping system on moisture and nitrogen in soils.] W. G. Wells. *Empire Cotton Growing Corpn., Progress Repts. Expt. Stas.* **1937–38**, 1–10(1939).—Detns. of moisture and nitrate were made during the period July-Oct. on soils where cotton had been grown continuously (I) and where cotton followed cotton following 3 seasons of growth of Rhodes grass (II). The moisture content was consistently higher in II. The nitrate content progressively increased from 0.25 to 5.10 p. p. m. in II and from 6.1 to 10.5 in I; it was consistently lower in II until the end of the following June. K. D. Jacob

An investigation of the problems of salt accumulation on a mallee soil in the Murray Valley irrigation area. J. E. Thomas. *Australia Council Sci. Ind. Research, Bull.* No. **128**, 88 pp.(1939).—A contour, vegetation, soil and salt survey was made of the selected virgin mallee area. The 3 soils in this area are Coomealla loam, Coomealla sandy loam and Barmera sand (cf. Marshall and Walkley, *C. A.* **31**, 8780[4]). The salt, mainly NaCl, distribution is irregular with a well-marked tendency to increase with depth. Apart from the general assocn. of the mallee communities with areas of high salinity and the natural assocn. of the bluebush with the low-lying areas of low surface salinity, there appears to be no general relation between vegetation and soil salinity. The development of salt after irrigation is assocd. with several features which include the original salinity, the soil type, the design of the holding, and the methods of irrigation. The original salinity appears to be of lesser importance than the soil type. Salty areas appear first on permeable soils in which free water accumulates at a relatively early stage. The significance of a free water table is discussed, and it is concluded that on soils of this type the surface concn. of salt at any time represents the net result of the upward movement of salt from the water table and the downward movement by leaching at irrigation. Extensive data and discussion are given on the field expts., factors affecting salt accumulation, soil changes under irrigation and on the method of salt prevention and soil reclamation. J. R. Adams

"Slick spots" in Nebraska. J. W. Fitts, H. F. Rhoades and E. S. Lyons. *J. Am. Soc. Agron.* **31**, 823–31(1939).—Mech. analysis, carbonates, pH, exchange capacity, exchangeable Ca, Mg, Na and K and percentage of satn. with Na and K are reported for slick spots and normal soils from 4 fields in the North Platte and Platte valleys of Nebraska. No consistent difference was found between

the $CaCO_3$ content of the particles less than 0.005 mm. of slick spots and normal soils. The slick spots were consistently higher than the normal soils in percentage of satn. with Na and K. The poor phys. properties of the slick spots were attributed to the higher content of exchangeable Na and K. A close relationship was found between the pH of the slick spots and normal soils and their resp. percentages of exchangeable univalent ions and $CaCO_3$. J. R. Adams

The cation effect upon the color values of humus materials. G. Halfter. *Bodenkunde u. Pflanzenernahr.* **14**, 322–45(1939).—Expts. with Merck's *acidum huminicum*, Cassel brown, *Rohstoff* from brown coal and peat showed that NaOH in addn. to that used in extn. invariably increased the depth of color to a max. corresponding to the *T*-value (total base absorptive capacity) of each material. Extn. with equimol. solns. of Li, Na and K oxalates gave color intensities decreasing in that order, and corresponding to the resp. dispersive powers. The effects of Ca to ppt. humus substances are best avoided by extg. with a mixt. of NaOH and $Na_2C_2O_4$. Mg has relatively slight effects compared to Ca. The Mg compd. with *acidum huminicum* is rather sol. in H_2O; those with Cassel brown and *Rohstoff* are practically insol. The form in which Ca occurs in soil is important in its effect upon humus extn. procedures; if as $CaCO_3$, Na_2CO_3 + $Na_2C_2O_4$ may be used for extn., but sorbed Ca produces NaOH, which has a greater solvent power. Thirty-five references. C. J. Schollenberger

The nitrogen economy of wheat soils. With special reference to nonsymbiotic nitrogen fixation. H. L. Jensen. *J. Australian Inst. Agr. Sci.* **5**, 154–9(1939).—*Azotobacter* is only sparsely represented in the soils of the wheat belt of New South Wales. In these soils the conditions for N fixation by *Azotobacter* are generally far from favorable, largely owing to acid soil reaction and P_2O_5 deficiency. Other microörganisms hardly come into consideration as nonsymbiotic N fixers of any significance. Nonsymbiotic N fixation on the basis of residues from crops, spontaneous vegetation, etc., could account for only about $^1/_4$ to $^1/_3$ of the N requirements of the wheat crop. It thus appears that nonsymbiotic N fixation is a minor and mostly a quite insignificant factor in maintaining the N content of soils under wheat cultivation. Rain water may bring down in 5 to 6 yrs. sufficient N for an av. wheat crop. J. R. Adams

Chromium in the soils of Western Samoa and Niue Island. K. S. Birrell, F. T. Seelye and L. I. Grange. *New Zealand J. Sci. Tech.* **21A**, 91–5(1939).—Lateritic soils high in total Cr are described. Methods for the *detn. of small amts. of Cr* in HCl and weak acid exts. are discussed. Cr in the soils of Samoa and Niue Island does not occur in exchangeable form and is considered to be nontoxic to plants. John O. Hardesty

Selenium in Canada. Horace G. Byers and H. W. Lakin. *Can. J. Research* **17B**, 364–9(1939).—The existence of an enormous area of seleniferous soil is revealed through the results of a reconnaissance examn. of portions of Alberta, Saskatchewan and Manitoba provinces of Canada. About 300 samples of shales, soils and plants were collected at 90 different locations. The Se content of the shales varied from 0.3 to 3.0 p. p. m., of the soils from 0.1 to 6 p. p. m. and of the vegetation from 3 to 4190 p. p. m. J. W. Shipley

The seleniferous Astragalus osterhoutii Jones. O. A. Beath. *Am. J. Botany* **26**, 729–30(1939).—*A. osterhoutii* grows only on seleniferous soils and can absorb Se in toxic quantities. The growth of *A. lonchocarpus* is not confined to seleniferous soils and it does not absorb Se in toxic amts. from such soils. Nelson McKaig, Jr.

Association of sulfate reduction in the soil with anaerobic iron corrosion. Edwin G. Pont. *J. Australian Inst. Agr. Sci.* **5**, 170–1(1939).—The presence of sulfate-reducing bacteria, high concn. of sulfides and low concn. of sulfates in the neighborhood of corroded pipes under the soil indicates that biol. sulfate reduction produces the free O which increases corrosion. J. R. Adams

The effect of soil reaction on the chemical composition of mulberry leaves and the growth of mulberry trees. Kiyotoki Kato and Sadatoku Miwa. *J. Sci. Soil Manure, Japan* **13**, 591–6(1939).—The mulberry grew best on a soil which had sufficient lime and had a weak acid reaction. The chem. compn. of mulberry leaves was influenced by the reaction of soils and was normal on soil of weak acid reaction. Y. Kamoshita

Boron in horticulture. E. L. Overholser, F. L. Overley and Len B. Wooton. *Proc. Wash. State Hort. Assoc.* **33**, 73–85(1937).—Samples of *water* from wells and springs in the vicinity of Wenatchee, Wash. contained only 0.02–0.08 p. p. m. of B. Cork spot of d'Anjou pears was not corrected by either tree injections or soil applications of either H_3BO_3, $Na_2B_4O_7$ or NH_4 borate, but CuB_2O_4 caused a significant reduction in the incidence of the disease. B treatments did not definitely improve the hard-end and black-end conditions of Bartlett pears, but there were indications that Mn may be helpful in reducing hard-end. The literature is reviewed. 31 references. K. D. J.

The effect of boron on sugar beets. Natalie Saru. *Kühn-Arch.* **48**, 1–51(1939).—H_2O economy, Ca metabolism and the effect of B on young plants in sand and H_2O cultures were studied before the symptoms of heart- and dry-rot became marked. The concn. of B giving the optimum effect was greater with increasing addns. of Ca. Root development was especially favored by B. Increasing the concns. of B to 5–10 mg. per pot improved the H_2O economy of the plants, giving a greater green wt. The dry wt. was hardly affected and the sugar content was lowered somewhat. B deficiency was compensated to a large extent by excess K. Variable pH values of the nutrient soln. from 5 to 8 had a negligible effect on the susceptibility of the plants toward the disease. The physiol. role of B in the plant is discussed and the hypothesis proposed that B is involved in the regulation of the K:Ca ratio. Fifty-three references. C. K. Horner

Brown-spotting of apricots, a boron-deficiency disease. H. O. Askew and W. R. Lloyd Williams. *New Zealand J. Sci. Tech.* **21A**, 103–6(1939).—B deficiency caused a browning of the flesh of apricots. Damage was most evident near the stem end of the fruit. A marked increase in the B content of the fruit, following treatment with 0.1% borax spray soln. or top-dressing with borax at the rate of 0.5 lb. per tree, was correlated positively with freedom from browning of the flesh. John O. Hardesty

The effect of cobalt compounds on the cobalt content of supplementary fodder crops. E. B. Kidson and P. W. Maunsell. *New Zealand J. Sci. Tech.* **21A**, 125–8(1939).—Turnips, swedes, rape and oats showed a marked increase in Co content as a result of using cobaltized superphosphate or $CoCl_2$ either for drilling with the seed or for top-dressing over the young plants. The increase in Co content appeared to be proportional to the amt. of Co applied. The effect of Co dressings persisted for several months. John O. Hardesty

The reciprocal action of the nutrients potassium and calcium dependent upon the crop plant, as with oats and flax. Egon Penner. *Bodenkunde u. Pflanzenernahr.* **14**, 204–30(1939).—Oats and flax were grown in Mitscherlich pots of sand and sand-soil mixts. completely fertilized and with K_2O and $CaCO_3$ addns. varied widely. In sand with a little $CaCO_3$, flax became chlorotic at an early stage, whereas in even the most heavily limed sand-soil mixts. the plants developed normally except for slight yellowing. Oats was not harmed by liming at any rate, nor by fertilization with KCl, which was always harmful to flax, attributed to increased mobilization of Ca. Oats and flax differ in degree of assimilation of nutrients at different stages of development. Young flax is highly sensitive but older plants are more tolerant to excess Ca. Fiber flax shows a heavy demand for K_2O at a later stage of growth, required for fiber production; much Ca must previously be assimilated and is utilized in forming the plant's mineral skeleton. The plant is able to take whichever element it requires at each stage of growth. The slightly developed capacity to utilize K_2O in the seedling stage is assocd. with a low assimilation of CaO; the process is not merely the selection of a certain material from soln., but

is accomplished through a considerable shift in the concn. of the ions of the substrate produced by internal growth factors. Fifty-two references. C. J. Schollenberger

The effect of calcium arsenate upon the yield of cotton on different soil types. Clarence Dorman and Russell Coleman. *J. Am. Soc. Agron.* **31**, 966–71(1939).—Cotton yields on Houston clay loam, Memphis silt loam, Sarpy silty clay loam, and Sarpy fine sandy loam were unaffected even by an application of 1600 lb. of $Ca_3(AsO_4)_2$ per acre. A beneficial effect was obtained on Ruston sandy loam from light applications and a detrimental effect from heavy applications of $Ca_3(AsO_4)_2$. However, the As toxicity was reduced with time. The beneficial effect was attributed to the applied Ca acting as a nutrient, the As liberating insol. P, and the $Ca_3(AsO_4)_2$ stimulating bacterial activity. The ability of the unaffected soils to render As insol. was probably due to their high pH and high colloidal content. J. R. Adams

Pot experiments with food plants. Arthur Taubitz. *Gartenbauwiss.* **13**, 354–405(1939).—In pot expts. the av. error appeared to depend upon yield. Greater accuracy was obtained by having a large no. of replicates or by using a particular type of plant which gives the most favorable response toward the nutrient. The exptl. accuracy was also increased by increasing contents of humus. Pure quartz sand was unsuitable as a substrate for the plants; the addn. of 1% peat mull acted very favorably, apparently improving the phys. condition and relative concn. of nutrients. The peat mull had no direct influence on the plant response toward N, K or P. Certain plants were found to be more favorable than others for studying the response toward a particular element. Low moor soil when mixed with the sand gave the same harvest yield and magnitude of error as the sand and peat mull mixt. Low moor soil inhibited the effect of P but not that of K. 45 references. C. K. Horner

Changes in the photosynthetic activity of plants during their growth and development as related to the problem of carbon dioxide fertilization. V. M. Katunskiĭ. *Bull. acad. sci. U. R. S. S., Sér. biol.* **1939**, 85–101(in English, 101–2).—Smoke gases, prepd. by catalytic combustion of fuel oil, wood, etc., and contg. up to 15% CO_2, are suitable for the atm. fertilization of plants. Fertilization with CO_2 gas is most effective if applied at those stages of development, different for different plants, when the accumulation of org. substances in the plant is greatest. For beans, peas and hemp this corresponds to the stage when the flower buds are just beginning to form. For oats it is at the tillering stage. John Lĭvak

Some factors controlling the yield of young cacao. II. F. W. Cope. *Ann. Rept. Cacao Research* **8**, 4–15(1938) (Pub., 1939).—Attempts to analyze the effects of fertilizers on the various stages which make yield possible gave no statistically significant results, except that K was beneficial in enhancing pod yields. Self-incompatible trees were benefited more than self-compatible trees by the application of fertilizers. K. D. Jacob

Investigations on the influence of fertilizing on the growth and development of the soybean. F. Alten and R. Gottwick. *Ernähr. Pflanze* **35**, 277–84(1939).—Comparative plot expts. were carried out over a period of 3 yrs. with soybeans receiving the following different treatments: unfertilized, N and P only, 3 types of complete fertilizer contg. different forms of K, namely, kainite, 40% K_2O salts and $K_2Mg(SO_4)_2$. The beans from plots receiving complete fertilizer contained more fat and lecithin and less crude protein than those from plots receiving no fertilizer or only N and P. The form of K had no effect on the fat content of the beans. The lecithin content of the beans was highest with complete fertilizer contg. $K_2Mg(SO_4)_2$. K fertilizers did not affect the K and P contents of the beans but increased the K content of the straw. Nutrient requirements of soybeans are discussed. J. O. H.

Reëstablishing and maintaining cover crops in apple orchards. O. M. Morris. *Proc. Wash. State Hort. Assoc.* **33**, 67–70(1937).—In greenhouse expts., addn. of Pb arsenate at the rate of 1 ton/acre to soil, collected from fields that had never grown an orchard nor been sprayed for any other crop, decreased the growth of alfalfa about 50%, as compared to that obtained on untreated soil. Only slight growth was obtained with larger quantities (2–5 tons/acre) of Pb arsenate. Neither F compds. nor Ca arsenate, at the rate of 1–5 tons/acre, had any ill effects on plant growth. With phenothiazine (1 ton/acre) a crop of weak, short-lived plants was produced and no crop was obtained with larger quantities. As_2O_3 (1–5 tons/acre) produced results similar to those obtained with Pb arsenate. Pb acetate (1–5 tons/acre) had no adverse effect, whereas $Pb(NO_3)_2$ (1–5 tons/acre) produced a distinctly better crop than was obtained on the untreated soil. An application of nitrogenous fertilizer, together with liberal quantities of easily decomposable org. matter, appeared to be the best procedure for overcoming the adverse effects of Pb arsenate on the growth of alfalfa in apple orchards. K. D. Jacob

Studies on the nutrition of tulips and narcissi. C. Bould. *J. Pomology Hort. Sci.* **17**, 254–74(1939).—Nutrition expts. on tulips and narcissi grown in sand over a period of 3 yrs. are described. The treatments were: complete nutrient soln., solns. omitting N, P and K, resp., and H_2O only. Omission of N produced typical deficiency symptoms in the foliage and a significant reduction in bulb-wt. increase. Omission of K caused a reduction in bulb-wt. increase but did not produce leaf scorch or affect the quality of the flowers. The treatments had no significant effect on the carbohydrate content of the bulbs during the 1st yr. but produced marked changes in their content of inorg. constituents. Data on the N, P and K contents of dormant bulbs may be useful in assessing the quality of an unknown stock. J. O. H.

Nutrient uptake of the tomato plant. A. H. Lewis and F. B. Marmoy. *J. Pomology Hort. Sci.* **17**, 275–83 (1939).—The course of uptake of N, P, K, Ca, Mg, Na, Fe, Mn, Cu, B, Cl and S by the tomato crop was studied. The relative proportion of nutrients in the crop was fairly const. throughout its whole life. The rate of nutrient uptake paralleled the rate of dry matter production, i. e., nutrient uptake was slow in the early stages, rose to a max. in June to July and then declined. The results suggest that a nutrient supply of const. compn. (N: P_2O_5: K_2O = 1.1 2) might be used and applied in amts. corresponding to the stage and rate of growth. John O. Hardesty

Fertilizer requirements of the potato on different soils of Alabama. L. M. Ware. *Am. Potato J.* **16**, 259–66 (1939).—Applications of K, P and N were necessary for highest yields on all soil types. Where no K had been applied to a Norfolk soil since clearing, only 56% of a full yield was obtained in the 1st 3 yrs. and only 37% in the 6th through 8th yrs. Only 7% of the max. yield was obtained the 1st yr. on newly cleared land that had never been fertilized with P. Without N the yield was 21% of the max. in the 1st yr. after clearing the land, 76% in the 2nd yr. and approx. 40–50% in the next 3 yrs. K. D. Jacob

Fertilizer experiments on cacao in Trinidad—summary of results for 1938. F. Hardy. *Ann. Rept. Cacao Research* **8**, 27–34(1938)(Pub., 1939); cf. *C. A.* **32**, 8058⁸.—The constituent of pen manure that causes increased yields of cacao on shaded trees is generally not N but K, though the cellulosic and other carbohydrate components and occasionally P may play a part. Apparently, trees of the Immortel, variety, as normally distributed in cacao fields in Trinidad and Tobago, are capable of providing, by the fall of leaves, twigs, flowers and fruits, sufficient N for the needs of the cacao crop and the soil's supply of N is enhanced by the presence of N-fixing organisms in the root nodules. On P-deficient soils superphosphate and other sol. phosphates give the quickest responses. In the case of available P_2O_5 (Truog test) the lower limits of adequacy in the surface 6-in. layer of cacao soils in Trinidad and Tobago are 50 p. p. m. for air-dry clay soils (index of texture above 25) and 30 p. p. m. for sandy soils (index of texture below 25). For available K_2O (exchangeable K, extractable by 0.5 *N* AcOH) the limits are 175 and 100 p. p. m., resp. The value and reliability

of these tests as a means of deciding initial deficiencies of P and K in such soils have been fully demonstrated. A remarkable response to an application of sucrose (3000 lb./acre) to an acidic alluvial sandy soil, where the yield of cacao was increased 24% in 1 yr., gave further evidence of the pos. relation between high yield and high C:N ratio. On black clay soil, applications of gypsum (6 lb./tree) had a small, but significant, depressing effect on yields of cacao, which was partially overcome by the simultaneous application of either superphosphate or double superphosphate. K. D. Jacob

Report of the Agricultural Chemist for 1938. [Decomposition of green material.] T. Eden. *Tea Research Inst., Ceylon, Bull.* No. 19, 57–64; cf. *C. A.* **32**, 2672⁵. —Under aerobic conditions, materials such as straw, gliricidia and weeds develop mucilaginous substances readily and the quantity increases with increase in the pH of the compost. Owing to the presence of tannin, refuse tea and tea pruning leaf produce little or none of these substances regardless of the pH and similar results are obtained when decompg. gliricidia is kept moist with an aq. ext. of tea leaf instead of plain water. The presence of tannin also completely inhibits formation of NH_4 compds. and nitrites during the aerobic fermentation of tea leaf, whereas a considerable portion of the N in green manures is converted into these forms. The pH values of 69 samples of various types of composts ranged from 6.0 to 8.0 and higher. K. D. Jacob

Phosphoric acid fertilization. Werner Selke. *Bodenkunde u. Pflanzenernähr.* **14**, 28–59(1939).—Three-yr. pot expts. with oats on neutral humus loess loam indicate that the citric acid-sol. P_2O_5 of ammoniated superphosphate with 7% N is inferior both to the P_2O_5 of basic slag sol. in the same soln. and to the H_2O-sol. P_2O_5 of plain superphosphate. The percentages of the P_2O_5 applied in these carriers which were utilized were 15.8, 31 and 39, resp. In similar expts. with barley on a sandy soil, pH_{KCl} 4.35, if the utilization of the P_2O_5 of Rhenania phosphate was rated at 100, that of the carriers named was, in order, 54, 106 and 29. Liming this soil changed the relative figures to 100, 76, 94 and 89, resp., but the liming released so much of the native P_2O_5 of the soil that the relative recovery of P_2O_5 was 76 when none was applied, indicating no return from ammoniated superphosphate. Seventeen references. C. J. Schollenberger

The activity of various newer phosphoric acid fertilizers compared with that of the forms previously used. R. Thun. *Bodenkunde u. Pflanzenernahr.* **14**, 112–32(1939). —In addn. to the new products discussed in the following abstrs., pot and Neubauer tests with the "Kaliglühphosphat" of Messerschmidt are included. It is made by calcining a mixt. of K_2SO_4 and Kola apatite, which is ⅓ nephelite; thus a silicophosphate similar to "Rhenania" is obtained. All the tests confirm the inferiority of "Réno" except on strongly acid soils, where it is better than raw phosphate rock. The other products are satisfactory P_2O_5 fertilizers for German soils in general. C. J. Schollenberger

The action and aftereffects of new phosphates. L. Schmitt. *Bodenkunde u. Pflanzenernähr.* **14**, 83–112 (1939).—The prepn. and compn. of the new P_2O_5 fertilizers discussed in the following abstr. are given in greater detail. Similar 3-yr. pot expts. with oats and red clover indicate that "Wasag" is equal to superphosphate on a sandy soil at pH 4.3, also when limed to pH 5.5 and 7.0. Detns. of soil pH indicated that it is physiologically neutral, but the tests indicate that it is the equal of basic slag for red clover. Essentially the same conclusions apply to "Lübeck" also, and in addn. it has a pos. value in overcoming soil acidity. "Réno," which is stated to be an imported product, is not adapted for use on any but strongly acid soils, mineral or org. The results with this product indicate that evaluation of raw or incompletely converted phosphates from soly. in 2% citric acid or citrate soln. is defective; only vegetation tests are trustworthy. C. J. Schollenberger

Pot experiments to ascertain the action of some newer phosphoric acid fertilizers. F. Giesecke, G. Michael and L. Kuhn. *Bodenkunde u. Pflanzenernähr.* **14**, 70–82 (1939).—"Réno" I and II are calcined Tunisian phosphate with 25 and 29% total, 11 and 14% P_2O_5 sol. in 2% citric acid soln., none sol. in H_2O, and basicity equiv. to 10 and 8% CaO, resp. "Lübeck" is made by calcining phosphate rock with Na_2SO_4 and coal dust, giving a product different from "Rhenania," also calcined but with Na_2CO_3 and SiO_2. "Wasag" is similar to superphosphate but is made with min. H_2SO_4 so that it contains no free H_3PO_4. "Lübeck" has basicity equiv. to 22% CaO, with 23.3% total P_2O_5, 22.6% P_2O_5 sol. in 2% citric acid and 1.2% P_2O_5 sol. in H_2O. "Wasag" contains 18.9% total, 17.6% citric acid-sol. and 15.3% H_2O-sol. P_2O_5, and has no basicity. Resp. figures for "Rhenania" and basic slag are 25.0 and 15.7; 23.3 and 14.8; 0.2 and 0.0; 11 and 25% CaO equiv. basicity. The foregoing and 18.5% P_2O_5 superphosphate (18.8% P_2O_5 sol. in H_2O) were compared in 2-yr. tests with oats in Mitscherlich pots, filled with glass sand, sand plus 2% peat, acid sandy heath soil, calcareous low moor soil and neutral loam, with the conclusion that all are satisfactory P_2O_5 fertilizers for German soils, excepting "Réno," which seems adapted only to acid humus soils. C. J. S.

The phosphoric acid fractions in oats grain and spinach leaves as affected by different phosphate fertilizers. A contribution on the problem of influencing quality by fertilization. G. Michael. *Bodenkunde u. Pflanzenernahr.* **14**, 148–71(1939). Oats grain grown in Mitscherlich pots used for a test on the utilization of P_2O_5 from various carriers (cf. preceding abstr.) was ground to meal and extd. with Et_2O, EtOH, $CHCl_3$, AcOH, HCl, etc., to sep. the different P_2O_5 compds. The methods so worked out were afterward applied to spinach similarly grown. Conclusions: The EtOH- and $CHCl_3$-sol. P_2O_5 appear to be identical, probably phosphatides, and the quantity in oats is fairly const. and independent of the total P_2O_5. Oats seedlings are especially rich and spinach leaves rather variable in their content of this fraction. The AcOH-sol. P_2O_5 is accompanied by most of the Ca and Mg of the material, and probably includes both org. and inorg. compds.; it varies markedly, but consistently with the total P_2O_5. HCl-sol. and residual P_2O_5 are likewise variable, but less so than the AcOH-sol. fraction, and are believed to be assocd. with nucleoproteins. Twenty-seven references. C. J. S.

Investigations on Wasag phosphate. L. Meyer. *Bodenkunde u. Pflanzenernahr.* **14**, 133–40(1939).— Observations and tests on the new P_2O_5 fertilizer "Wasag" (I) (cf. 2nd preceding abstr.) indicate good storage qualities, caking less and not reverting much more than standard superphosphate (II), and in mixts. with 40% K_2O salt or kainite the mech. properties are better. Extn of small samples with pure and CO_2-satd. water shows slower removal of P_2O_5 than from II, but Neubauer tests with various soils known to have strong fixing powers for P_2O_5 indicate equal availability of the P_2O_5 from each after 6 months in the soil. C. J. Schollenberger

Pot experiments for evaluating some new phosphoric acid fertilizers—Wasag and M (Lübeck) phosphates. F. Nieschlag and C. Windorf. *Bodenkunde u. Pflanzenernähr.* **14**, 141–8(1939).—Mitscherlich pots of 3 acid soils limed and completely fertilized with 100, 300 and 900 lb. P_2O_5/acre in various carriers mentioned in the 3rd preceding abstr. were seeded to oats. Yields and compn. of the crop indicated that "Wasag" is equal to superphosphate, and the value of the P_2O_5 in this material corresponds to the NH_4 citrate soly. The "M (Lübeck)" phosphate gave inferior results, perhaps because of the liming. C. J. Schollenberger

Production and action of a mixed fertilizer containing urea from calcium cyanamide and potassium sulfate. H. Kappen. *Bodenkunde u. Pflanzenernahr.* **14**, 380–4(1939).—A concd. fertilizer can be prepd. by the reactions

$$Ca(HCN_2)_2 + K_2SO_4 + H_2O \rightarrow 2KHCN_2 + CaSO_4 \quad (1)$$
$$KHCN_2 + H_3PO_4 \rightarrow KH_2PO_4 + H_2CN_2 \quad (2)$$
$$H_2CN_2 + H_2O\ (MnO_2\ \text{catalyst}) \rightarrow CO(NH_2)_2 \quad (3).$$

The final soln. is evapd. to obtain a residue contg. about 15% N (0.7% N still in $(H_2CN_2)_2$), 27% P_2O_5 and 25% K_2O. Mitscherlich pot tests with summer barley, comparing the above product and the usual fertilizers carrying the same nutrients, indicated that it is equal to any fertilizer. C. J. Schollenberger

Manufacture of boron-magnesium fertilizers from mother liquors of boric acid manufacture. L. Berlin. *Novosti Tekhniki* **1939**, No. 3, 39-40.— The mother liquors obtained in the crystn. of H_3BO_3 from Inder borates contg. H_3BO_3 2, free H_2SO_4 0.6 1, $MgSO_4$ 21–24, and admixts. under 1% are neutralized with $CaCO_3$ and dried until solid. The product contains 6–8% H_3BO_3 and may be used as a fertilizer. B. Z. Kamich

Industrial and agricultural utilization of defecation slime. O. Spengler. *Centr. Zuckerind.* **47**, 762(1939).— Moist defecation slimes were too viscous to give uniform distribution in lime-deficient soils. Attempts to recover lime and other useful products from dried slimes failed. W. W. Binkley

The decomposition of blast-furnace slag. Günther Naumann. *Bodenkunde u. Pflanzenernahr.* **15**, 74–126 (1939).—Slags of varied compn. and mech. treatment from many German furnaces and generally of fineness such that 65–90% was within the limits 0.02–0.2 mm. were investigated as to soly. of the CaO and MgO with 1 g. substance/1 l. of plain and carbonated water, and behavior on hydrothermal treatment and electrodialysis with the app. of Loddesol (*C. A.* **26**, 1160), including x-ray spectra of the residues. Equil. expts. indicated that up to 16% in the case of sprinkling-cracked slags, 11% and 6% of the CaO of massive and granulated slags, resp., were sol. in H_2O; in CO_2-satd. H_2O, these figures were about 4 times as high, and considerable MgO also appeared in soln. The time curve of decompn. by these solvents, as measured by bases dissolved, was approx. logarithmic. Rate and abs. soly. increased with temp., and the influence of surface as detd. by particle size and of the ratio of water to slag was great. The rate and extent of decompn. were greatly increased by electrodialysis, and SiO_2, Al_2O_3, FeO and MnO were thereby brought into soln. Examn. of the residues for H_2O content and soly. in KOH soln. showed that electrodialysis caused the formation of colloidal substances; except with one glassy slag, no recrystn. of the gels was shown by x-ray examn. after hydrothermal treatment, but the spectra indicated that under conditions resembling those of the soil, the originally coarsely cryst. slag particles in time became finely cryst. It is concluded that the rate of attack by solvents in the soil decreases with time, from the formation of a protective envelope of colloidal SiO_2 and Al_2O_3 over the particles, as well as for other reasons. The productivity of soils can be improved by the colloids and bases supplied, and ground slag is considered a promising liming material, possibly excepting the granulated material, which was indicated by this work to be less sol. than others of comparable fineness and compn. Twenty-nine references. C. J. Schollenberger

Control of the purple scale and the Florida red scale. Max R. Osburn. *J. Econ. Entomol.* **32**, 688–90(1939).— A spray of 2% lime-S soln. and 5 lb. wettable S in 100 gals. water reduced populations of purple scale (*Lepidosaphes beckii*) but was ineffective against the red scale (*Chrysomphalus aonidum*). A petroleum oil spray (an emulsion contg. 83% of light-medium oil; 92% sulfonated residue), used at 1.6% concn., was more effective than the S spray against purple scale but did not furnish satisfactory control of the red scale. C. H. Richardson

Insecticides for June beetle control. Bernard V. Travis and G. C. Decker. *J. Econ. Entomol.* **32**, 607–11 (1939).— In lab. tests with adult *Phyllophaga implicita*, light applications of $PbHAsO_4$ (1–1.5 lb. per tree) killed 74–90% of the beetles, moderate applications (3 lb. per tree) 81–95% and heavy applications (4.5 lb. per tree) 88–98%; Ca arsenate was less effective, light, moderate and heavy applications killing 18–52%, 36–70% and 51–84%, resp., of the beetles; Ca arsenate was also less effective in field tests. Mg arsenate and Na_2SiF_6 were ineffective. The beetles fed longer on foliage dusted with $PbHAsO_4$ than with Ca arsenate. Sprays of the arsenates used were less effective than the dusts, the waxy coating of the leaves preventing an even coating of the leaf surfaces. C. H. Richardson

Control of borers in newly set shade trees. M. D. Farrar. *J. Econ. Entomol.* **32**, 634–8(1939).—Mech. protection by wrapping paper was superior to a $C_{10}H_8$ repellent, a nicotine soln. and a miscible oil contg. *p*-$C_6H_4Cl_2$. C. H. Richardson

Further studies with ethylene dichloride emulsion for the control of the peach borer. Oliver I. Snapp. *J. Econ. Entomol.* **32**, 683–5(1939); cf. *C. A.* **33**, 2273[2].— This emulsion continues to give better results than *p*-$C_6H_4Cl_2$ against *Conopia exitiosa*. A new simplified formula for making the emulsion requires the addn. of 8 vols. of water to 1 vol. of K-fishoil soap (contg. approx. 30% soap) and then 9 vols. of ethylene dichloride. The mixt. is emulsified by pumping in the cold. C. H. R.

Soil treatments for the control of the fire ant, Solenopsis geminata (F.). Bernard V. Travis. *J. Econ. Entomol.* **32**, 645–50(1939).— NaCN, $Ca(CN)_2$, $C(NO_2)Cl_3$, CS_2, CCl_4, SO_2, S, NaF and derris were used in various ways to control this insect. Repeated applications of aq. solns. of NaCN into the nests greatly reduced the no. of ants but failed to eliminate them, and actually increased the no. of colonies. Solid NaCN was less effective than the solns. $Ca(CN)_2$, as a dust, gave slightly better results than NaCN but was more expensive. S, NaF and derris were ineffective; the other compds. controlled the ants only when the applications were so large that the expense was prohibitive. C. H. Richardson

Experiments using several insecticides with and without wetting agents and stickers for boll-weevil control. C. F. Rainwater. *J. Econ. Entomol.* **32**, 700–3(1939); cf. *C. A.* **33**, 2273[1].—Cotton plants infested with *Anthonomus grandis* were dusted with the following insecticides: Ca arsenate, nicotine bentonite, nicotine bentonite + nicotine tannate, finely ground synthetic cryolite contg. 90.8% Na_3AlF_6, coarsely ground cryolite contg. 78.3% Na_3AlF_6, and a mixt. of Ca arsenate and $CaCO_3$ without spreader or sticker. The following com. wetting agents and stickers were used: Na salt of an alkylated naphthalenesulfonate, monosodium sulfonate of butylphenylphenol, a sulfonated alkylated biphenyl, a synthetic liquid sticker and spreader, and a dry gum contg. a tapioca base. None of the wetting agents or stickers increased the effectiveness of Ca arsenate or the nicotine prepns.; the synthetic liquid sticker made the finely ground cryolite equal in effectiveness to Ca arsenate. The nicotine prepns. were inferior to Ca arsenate and cryolite. Cryolite might become a satisfactory substitute for Ca arsenate; it should have good dusting qualities and a high content of Na_3AlF_6. C. H. Richardson

The use of phenothiazine in the medication of cattle for the control of horn flies. W. G. Bruce. *J. Econ. Entomol.* **32**, 794–6(1939).—This is a continuation of studies previously reported (Knipling, *C. A.* **32**, 7650[6]). The min. dose of the compd. fed in bran to cattle which would kill all the larvae of *Haematobia irritans* was 22 mg. per kg. of body wt. of the animal. The manure from animals fed this dose was unfavorable for the development of horn-fly larvae for approx. 24 hrs. beginning 12 hrs. after administration. Mixed directly with the droppings the min. lethal dose was 4 mg. per 100 g. droppings. C. H. Richardson

The control of Diaprepes abbreviatus L. and Lachnosterna (Phytalus) smithi arrow, in Barbados surveyed over a period of eleven years. R. W. E. Tucker. *Agr. J.* (Barbados) **8**, 8–18(1939).—Tests with soil fumigants and contact insecticides (9 different treatments) against root borers and brown hard backs give little promise. The soils of Barbados are too heavy and impervious to warrant soil treatments. The control of these 2 pests depends upon (*a*) hand collection of adults and egg masses in cane fields and (*b*) cultural methods. J. R. A.

Report of the Imperial Entomologist. Hem Singh Pruthi. *Sci. Repts. Imp. Agr. Research Inst., New Delhi*

1937–38, 113–28.—Hoppers and adults of *Poecilocerus pictus* on brinjal plants were effectively controlled by spraying with Na arsenite (2 lb./100 gal.). Pb arsenate sprays, Na_2SiF_6 baits or Na_2SiF_6 and lime dusts were ineffective. Na_2SiF_6 baits were highly effective in controlling crickets (*Gryllus domesticus*) damaging rayon in a textile mill. Sugar-cane setts were protected against white ants by immersing the setts, immediately before planting, for 0.5–1.0 min. in either 5% Pb arsenate soln. or 2% soln. of Paris green mixed with 4% soln. of lime and drying in the shade. Attack of the ants was deterred but not prevented by treating the setts with 5% soln. of Na_2SiF_6 or smearing the ends with coal tar. Young cucurbit crops were protected against the pumpkin beetle (*Aulacophora foveicollis* (Lucas)) by dusting 2–3 times at weekly intervals with a 1.80 mixt. of Paris green and wood ashes. K. D. Jacob

The use of chlorinated nitrobenzenes for the control of club-root disease of Brassica. Margaret J. Smieton. *J. Pomology Hort. Sci.* **17**, 195-217(1939).—Pentachloronitrobenzene (I), trichloronitrobenzene (II) and $HgCl_2$ were compared in seed-box expts. for the control of club-root disease (*Plasmodiophora brassicae*). I and II were com. prepns. contg. 20% active ingredient. II was sometimes as efficient as $HgCl_2$ and was superior to I. In outdoor seed-bed trials II, applied at the rate of 1.5 to 3 oz. per sq. yd., gave a varying degree of control depending on the degree of soil contamination. Substantial control of the disease was obtained by the addn. of a small amt. of II, dild. with soil, to the dibble hole at the time of transplanting. These fungicides are liable to check the growth of the plants. A method of applying the fungicides by dipping the plant roots in a wet mixt. of fungicide and soil previous to transplanting was inferior to the standard dibble-hole method. Promising results were obtained by broadcasting the fungicides. John O. Hardesty

South Africa Cotton Experiment Station, Barberton. Progress report for the season 1937–38. Rotation crops. [Grain moth and weevil control in stored maize.] M. F. Rose. *Empire Cotton Growing Corpn., Progress Repts. Expt. Stas.* **1937–38**, 23–7(1939).—In expts. with borax, $Ca(OH)_2$, Na_2SiF_6, flaked naphthalene and NaF, the best control was obtained with NaF used at a 1 1000 wt. ratio. As compared to results obtained with maize fumigated with CS_2 (3 lb./1000 cu. ft. at monthly intervals), a single application of NaF (wt. ratio of 2 1000), mixed with the grain approx. 4 months before planting, delayed germination, reduced the percentage of seeds germinating and markedly retarded growth of the plants in the early stages. In tray expts., CS_2 had a definite stimulating action on germination. K. D. Jacob

Animal pests. Rose thrips (Thrips fuscipennis Hal.). E. R. Speyer. *Exptl. Research Sta., Turner's Hill, Herts, Ann. Rept.* **24**, 64–6(1938)(Pub. 1939).—In lab. expts., rose leaves dusted with pyrethrum produced paralysis of the thrips in 10–20 min. and a total mortality in 2 days. In sunlight the lethal action was lost in 24 hrs., but a deterrent effect persisted for at least 3 days. A 1% soln. of potash soft-soap contg. 0.2% nicotine was very effective during the 24-hr. period following its application but rapidly lost its toxic action thereafter. Derris sprays and dusts gave erratic results. **Leaf-miners of glasshouse plants.** *Ibid.* 67–73.—Tomato leaves sprayed with solns. contg. 0.15–0.25% Na_2SiF_6 and 2.0–2.5% sugar were lethal to the adult tomato leaf-miner (*Phytomyza solani* Macq.). Nicotine sulfate sprays (nicotine concn. 1:650–800) with saponin (4 oz./100 gal.) as a spreader were also lethal to adult insects, but neither these sprays nor combinations thereof with derris controlled the larval stages in mined leaves. Adults of *P. atricornis* Mg., *P. ranunculi* Mg. and *Delia brunnescens* Zett. were attracted to and killed by foliage that had been sprayed with a soln. of Na_2SiF_6 0.2 and sugar 2.0%. **Angle-shades moth (Brotolomia meticulosa L.).** *Ibid.* 73–4.—The insect was controlled on chrysanthemums by spraying the plants with Pb arsenate (6 oz. paste per 100 gal. water) up to a period of 3 weeks before the blooms were ready for the market. Later appearances of the caterpillars were controlled by lightly dusting the open blooms with finely powd. cryolite unmixed with a filler. **Yellow underwing moth (Triphaena pronuba L.).** *Ibid.* 74–5.—The larval stages of the insect were quickly killed when fed either carnation plants dusted with derris powder or a bait contg. bran 28, Paris green 1 part and sufficient molasses (5–7% soln.) to moisten. **Aphids in glasshouses.** *Ibid.* 76–7.—The rose aphis (*Macrosiphum rosae* L.) was controlled in com. nurseries by applications of pyrethrum powder. The chrysanthemum black-fly (*Macrosiphum sanborni* Gill.) was destroyed on young plants by a single application of a spray contg. nicotine (95–98%) 10 fluid oz. and soft soap 8 lb./100 gal. water. Fumigation of glasshouses with $Ca(CN)_2$ (0.25 oz./1000 cu. ft.) did not control the arum green-fly (*Mygus circumflexus* Buckt.). **Mushroom flies.** *Ibid.* 77.—There was evidence that Sciarid flies are attracted to baits contg. a mixt. of ale and treacle, but Phorid flies principally to treacle alone. Male Sciarids, but not the females, appeared to be repelled by baits contg. 1% AmOAc. **Control of the carnation Tortrix moth (Tortrix pronubana Hb.) on pot plants.** O. B. Orchard. *Ibid.* 77–8.—Satisfactory results were obtained by spraying nonflowering plants with Pb arsenate paste 10 and saponin 0.5 oz./100 gal. Nicotine and derris sprays and dusts were ineffective. **Control of capsid bugs [Lygus pratensis L.] on chrysanthemums.** *Ibid.* 79–82.—Derris, S and nicotine dusts were ineffective. Nicotine sprays were highly efficient when applied during periods of sunshine. The insect was satisfactorily controlled by fumigating glasshouses with Cyanogas (0.33 oz./1000 cu. ft.). **The use of derris extracts in combination with petroleum oil emulsions.** W. H. Read. *Ibid.* 82–3.—Petroleum oil emulsions, dild. to 1:100 and contg. 0.007% rotenone, gave complete control of tomato-moth caterpillars (*Polia oleracea*). Combination sprays of petroleum oil emulsion and derris ext. gave better control of *red spider mites* than did those contg. derris alone. **The control of red spider mites on carnations.** *Ibid.* 84–5.—Good control of the mites, including eggs, without injury to the foliage was obtained by spraying with either a 0.17% soln. of dodecyl thiocyanate or a synthetic wax emulsion consisting of an emulsified soln. of chlorinated naphthalene in benzene used at a dilu. of 1:160 with addn. of 0.125 fluid oz. of spreader (Liquid Agral Wetter). The latter spray was somewhat more injurious than the former to the petals of open flowers. **Cucumber root fly maggot investigations.** *Ibid.* 85–6.—Control of the maggots of *Plastosciara perniciosa* and *Pnyxia scabiei* in cucumber beds was not obtained with a wide variety of insecticides, including nicotine-contg. emulsions of either sulfonated petroleum oil or tar acids. K. D. Jacob

Toluene compounds to control plant disease. Helen Hart and J. L. Allison. *Phytopathology* **29**, 978–81(1939).—Toluenesulfonylamides proved very effective in greenhouse expts. in controlling leaf rust as *Puccinia triticina*. R. C. Burrell

Damping-off of lettuce. H. L. White. *Exptl. Research Sta., Turner's Hill, Herts, Ann. Rept.* **24**, 56–8(1938)(Pub. 1939).—Damping-off of lettuce seedlings in soil cultures contaminated with *Rhizoctonia* was not prevented by pretreating the soil with either Cu_2O dust or aq. solns. of Cheshunt compd. The fungicides had no deleterious effect on germination of the seed. K. D. Jacob

Verticillium wilt of the carnation. H. L. White. *Exptl. Research Sta., Turner's Hill, Herts, Ann. Rept.* **24**, 49–53 (1938)(Pub. 1939).—Growth of *V. cinerescens* (the causal organism) on agar enriched with Richard's soln. was prevented by the presence of a 1:100,000 concn. of malachite green. Control of the disease on carnation cuttings was not effected, however, by immersing the severed ends of the cuttings overnight in a 1:50,000 aq. soln. of the dye, because of failure of the dye to penetrate the cutting to a sufficient depth. K. D. Jacob

Yellow patch of tobacco seedlings. L. F. Mandelson and E. C. Tommerup. *Queensland Agr. J.* **52**, 280–94 (1939).—In affected seedbeds the germination of the seed

is poor, patches or groups of plants are dwarfed and may turn pale green or yellow about 10 days after emergence, before they eventually die, thereby causing a poor and uneven stand of seedlings. The condition appears to be a physiol. disease assocd. with the use of excessive quantities of org. N in mixed fertilizers applied to the seedbeds and is probably caused by the accumulation of free NH_3 in the soil. Application of 0.1 oz. N as dried blood per sq. yd. retarded growth and practically none of the seedlings survived when the application exceeded 0.5 oz. Although the toxicity was not permanent and disappeared in time, it could not be rectified by adding either $KMnO_4$, MnO_2 or $CuSO_4$ to the soil. Yellow patch did not develop when only $NaNO_3$ was used in various quantities as the source of N. K. D. Jacob

Further investigations on the leaf edge disease of currant caused by chlorides. Karl Boresch. *Bodenkunde u. Pflanzenernähr.* **14**, 230–47(1939); cf. *C. A.* **33**, 3027.— Chloride fertilizers frequently cause currant leaves to show a blighting at the edges resembling a symptom of K_2O deficiency, when the latter may be present in sufficient amt. for normal requirements but not sufficient to combine with all the Cl in the leaves; the excess Cl is combined with Ca, and an antagonism between K and Ca produces the symptoms of K starvation. Pot expts. with CaO and NaCl addns. showed that red currants and *Ribes alpinum* are sensitive to Cl and excess CaO, whereas black currant is not. Ten references. C. J. Schollenberger

Study and control of antirrhinum rust. Amin Fikry. *Ministry Agr. Egypt, Tech. Sci. Service, Bull.* **223**, 16 pp. (1939).—Complete control of the disease, caused by *Puccinia antirrhini*, was obtained by dusting the plants at intervals of 2-3 weeks with S or by spraying with a mixt. of colloidal S 0.5 and soap 0.25%, beginning immediately after the fungus made its appearance. Lime-S, colloidal Cu, Bordeaux mixt., Burgundy mixt. and $CuSO_4$ sprays were only partially effective. K. D. Jacob

Effect of sulfuric acid treatment on fungi and bacteria present on cottonseed from diseased bolls. Douglas Bain. *Phytopathology* **29**, 879-84(1939).—Cottonseeds from bolls infected with *Bacterium malvacearum* were treated with concd. H_2SO_4 for 15, 30, 45 and 60 min. With the longer acid treatment, fewer fungi and bacteria were obtained when the seeds were cultured on potato-dextrose agar. Addnl. treatments with $HgCl_2$, 1 to 1000 in 50% alc., had no marked effect upon the nos. of seed-borne organisms. R. C. Burrell

Tests with various elm-wood traps for bark beetles. R. R. Whitten and W. C. Baker. *J. Econ. Entomol.* **32**, 630–4(1939).—Elm trees were treated with $NaClO_3$, $FeSO_4$ and $CuSO_4$ by a method (Lantz, *C. A.* **32**, 5988[8]) which introduces solns. of the compds. into the living tree. Trees treated with $NaClO_3$ were most attractive to bark beetles (*Scolytus multistriatus; Hylurgopinus rufipes*); the trees so treated were more attractive to these beetles than felled trees. C. H. Richardson

Habits of the June beetle, Phyllophaga lanceolata (Say) in Iowa [and response to aromatic compounds]. Bernard V. Travis. *J. Econ. Entomol.* **32**, 690–3(1939).—Of 24 org. compds. tested, mostly esters, alcs., aldehydes and amines, only one, isoamylamine, proved attractive, and this one only to the males. The response of the males to this compd. was similar to that produced by crushed or sexually active females. C. H. Richardson

Poisoned bait tests against the fire ant, with special reference to thallium sulfate and thallium acetate. Bernard V. Travis. *J. Econ. Entomol.* **32**, 706–13(1939).— Tl_2SO_4, in bait concns. of 1 to 2%, was toxic in lab. tests to *Solenopsis geminata* but not in the field. Tl acetate in bait concns. of 2–4% was very effective in lab. and field tests. A large no. of other insecticides gave neg. results. The addn. of Na benzoate and tartaric acid to the baits rendered them repellent. Insol. insecticides could not be studied adequately since the ants suck the liquid material out of the baits and avoid the solid particles. C. H. Richardson

Effects of acid arsenate of lead used against the termite, Reticulitermes flavipes (Kollar). Thomas J. Headlee and D. Manley Jobbins. *J. Econ. Entomol.* **32**, 638–40(1939). —Field tests showed that $PbHAsO_4$ protected white pine boards buried in soil contg. 0.05 lb. or more arsenate per cu. ft. from termite infestation. Protection endures for a long time even when the soil is fully exposed to weathering. The method appears to be cheap and practical. C. H. Richardson

Effects of heat-treatments of some calcium arsenates on their toxicities to silkworms and bean plants. J. W. Bulger and O. A. Nelson. *J. Econ. Entomol.* **32**, 615–19 (1939).—Pure Ca arsenates of 4 different CaO/As_2O_5 ratios (I, $CaO.As_2O_5.2H_2O$; IIa, $2CaO.As_2O_5.3H_2O$; IIb, $2CaO.As_2O_5.5H_2O$; III, $3CaO.As_2O_5.8H_2O$; IV, $4CaO.As_2O_5.xH_2O$) were prepd.; a sample of each was ignited to a glowing red to obtain the corresponding anhyd. compd. The hydrous and anhyd. compds. were tested for toxicity to silkworm larvae (*Bombyx mori*) by a leaf sandwich method, and to bean plants (variety Red Valentine) when applied as sprays (3 lb. in 100 gal. water). All the hydrous compds. were fairly toxic to the larvae (median lethal dose (M. L. D.) 0.04 to 0.18 mg. per g. body wt.) while the anhyd. compds. were practically nontoxic. Toxicity to bean plants paralleled that to the larvae. Compd. III when heated 3 hrs. at 500° did not show a great loss of toxicity to the larvae; but when heated 3 hrs. at 800° it became relatively nontoxic. Compd. IV gave M. L. D. 0.10–0.12 and no plant injury. It was therefore used in subsequent expts., com. samples of it being subjected to autoclave and dry-heat treatment at various temps. Autoclaved at 100° for 1 hr. and dried at the same temp. for ½ hr., IV was still fairly toxic; but when autoclaved for 3 hrs. and dried 1 hr., or autoclaved at 182° for 1 hr. or more, the compd. became relatively nontoxic. Dry heating of IV at 100° and 180° for 3 hrs. had little effect on toxicity while heating at 500° for ½ hr. or more made the compd. relatively nontoxic. Compds. I, IIa and IIb were about equal in toxicity to the larvae and about twice as toxic as compds. III and IV. Ignition decreased the percentage of sol. As in the compds.; but there was no evident correlation between percentage of sol. As and toxicity to insects or plants. C. H. R.

Lead and arsenic residues resulting from several spray schedules and materials, Lafayette, 1937. C. L. Burkholder, O. W. Ford and D. L. Johnson. *Trans. Indiana Hort. Soc.* **78**, 139–43(1938)(Pub., 1939).—Data are given on the Pb and As residues on apples at various periods during the use of 7 different spray programs. The spray deposit can be increased during the 1st brood codling-moth egg hatch by adding 0.5% of summer oil to the Pb arsenate spray, but such treatment has the disadvantage that the spray deposit is much higher at harvest in seasons of normal rainfall than is that obtained with Pb arsenate-lime sprays. The value of soybean flour as a builder and sticker with lime and Pb arsenate has not been definitely proved. Sprays composed of Pb arsenate, lime and soybean flour can be rendered more resistant to weathering by the addn. of 1 pint soybean oil per 100 gal. K. D. J.

Some types of injury to apples and pears from spraying and washing. F. L. Overley and E. L. Overholser. *Proc. Wash. State Hort. Assoc.* **33**, 143–52(1937).—Five types of injury are described and their causes are discussed. K. D. Jacob

Residue-removal studies for 1937. F. L. Overley, Kermit Groves, E. L. Overholser and J. L. St. John. *Proc. Wash. State Hort. Assoc.* **33**, 137–41(1937).—Data are given on the effectiveness of various washing procedures in removing As, Pb and F from apples sprayed with Pb arsenate, Ca arsenate or cryolite. Soda ash was equal to Na silicate in removing Pb from early washed fruit but was not so effective later in the season after the soft wax had developed. Tandem HCl washes were not so effective as tandem washes with either Na silicate or soda ash and HCl. Stored fruit was cleaned more readily when Na silicate was used with HCl than with other combinations. Fruit difficult to clean at harvest time without producing injury was successfully cleaned with a tandem wash of Na silicate and HCl after a period in storage at higher temps.

with less injury than when washed shortly after harvest. K. D. Jacob

Ease of residue removal from late and early spray applications of lead arsenate to apples. Jack E. Fahey, Harold W. Rusk, Loren F. Steiner and R. F. Sazama. *J. Econ. Entomol.* **32**, 714–17(1939).—The residue at harvest from $PbHAsO_4$ sprays increases as the time of spray application approaches harvest time. A final spray may leave at harvest a residue load equal to the load from 4 first-brood sprays. Residues from 2nd-brood sprays are more easily removed than those from the same no. of first-brood sprays. The use of oil adhesives with org. insecticides in 2nd-brood sprays makes the $PbHAsO_4$ from first-brood applications as difficult to remove as the residues from $PbHAsO_4$ used throughout the season. HCl solns. were used to wash the apples in these expts. C. H. Richardson

Aftereffects of the contact dust "Lipan" on the pine moth surviving the poisoning. Fritz P. Müller. *Forstwiss. Centr.* **61**, 538 44(1939).—Surviving moths, chrysalis, larvae and eggs, which were gathered from trees that had been dusted, showed but slight differences in viability and development over those obtained from sections that had not been treated. The chief differences were a somewhat greater mortality of the younger larvae and a lower wt. of the pupae. C. K. Horner

Increases in citrus scale infestations from heavy residue and from copper spray mixtures. Herbert Spencer. *J. Econ. Entomol.* **32**, 686 8(1939).—Heavy residues on citrus from sprays contg. $Ca(OH)_2$ increase the infestations of purple scale (*Lepidosaphes beckii*) and Florida red scale (*Chrysomphalus aonidum*); the presence or absence of Cu is unimportant. The results of expts. suggest that scale increases after application of Bordeaux mixt. may be reduced by decreasing the $Ca(OH)_2$ in the sprays to a quantity as low as horticultural or pathol. considerations will permit. Charles H. Richardson

A bibliography of cyanide compounds used as insecticides, 1933. H. D. Young. *U. S. Dept. Agr., Bur. Entomol. Plant Quarantine* **E-493**, 40 pp.(Sept., 1939); cf. *C. A.* **31**, 1943¹.—Abstracts of 191 papers and patents. **A bibliography of cyanide compounds used as insecticides, 1934.** H. D. Young and R. L. Busbey. *Ibid.* **E-494**, 57 pp.(Oct., 1939).—Abstracts of 269 papers and patents. K. D. Jacob

Chlorine gas as a seed disinfectant. R. W. Leukel and O. A. Nelson. *Phytopathology* **29**, 913–14(1939).—The effect of Cl_2 gas on smuts, wheat bunt and weevils was studied. It was not adaptable to the continuous type of seed-treatment equipment in common use. R. C. B.

Some results from insecticides. A. Kelsall. *Ann. Rept. Nova Scotia Fruit Growers' Assoc.* **75**, 59–61(1938).—Pyrethrum and derris sprays were entirely ineffective against rosy aphids and lauryl thiocyanate sprays were only partially effective. The best results were obtained by the use of either nicotine sulfate (1 pint per 100 gal.) in combination with fungicidal sprays or by coal-tar oil sprays. Arsenical insecticides, in addn. to acting as poisons against insects, appreciably improved the fungicidal value of flotation S sprays. The value of flotation S sprays was not impaired by the addn. of 3–5 lb. hydrated lime per 100 gal. and the lime prevented arsenical injury when such sprays were used in combination with Ca arsenate. Effective control of the gray banded leafroller was obtained with sprays of either Ca arsenate or Pb arsenate, particularly the latter. Derris, pyrethrum, cryolite, phenothiazine, nicotine sulfate and Black Leaf 155 (an insol. combination of nicotine sulfate and bentonite) were ineffective. Applications of Black Leaf 155 prevented deer from feeding on the foliage of treated trees. K. D. Jacob

The laboratory-field method for testing codling-moth insecticides. L. F. Steiner. *U. S. Dept. Agr., Bur. Entomol. Plant Quarantine* **E-488**, 10 pp.(Sept., 1939).—A discussion of the advantages and disadvantages of the so-called apple-plug method (cf. Lathrop and Sazama, *C. A.* **26**, 2815; Siegler and Munger, *C. A.* **27**, 4017). K. D. Jacob

Estimation, by the rotenone determination, of the insecticidal value of plants containing rotenone. A. Guillaume and G. Hervé. *Rev. botan. appl. agr. trop.* **19**, 552–64(1939).—In detg. the rotenone content of plants care must be taken to obtain a representative sample, as different parts of the same root do not contain the same quantity of rotenone and small roots are richer in rotenone than large roots. The method of detg. rotenone by crystg. a rotenone salt from a solvent and weighing the crystals is very unsatisfactory. The estn. of rotenone by measuring the MeO groups or by the colorimetric method is discussed and some modifications are suggested. J. R. Adams

The use of pyrethrum in the control of fruit insects. A. Kelsall. *Ann. Rept. Nova Scotia Fruit Growers' Assoc.* **74**, 84–7(1937).—Excellent control of the blunt-nose leafhopper was obtained by dusting cranberry bogs with a mixt. of pyrethrum 30 and gypsum 70% at the rate of 100 lb./acre. Applications of the dust (50–90 lb./acre) to apple trees gave effective control of the green apple bug and the red apple bug. Pyrethrum spray (3 lb./100 gal.) controlled the green apple bug, but its effectiveness seemed to be reduced by addn. of Fe sulfate. The apple leafhopper was readily controlled by either pyrethrum dust or spray. K. D. Jacob

Codling-moth insecticide investigations in 1938 at the Vincennes laboratory. L. F. Steiner, J. E. Fahey and S. A. Summerland. *Trans. Indiana Hort. Soc.* **78**, 86–99 (1938)(Pub. 1939); cf. *C. A.* **32**, 293⁶.—The best control was obtained with a tank-mixed combination of 40% nicotine sulfate 1 pint, soybean oil 1 quart, Na lauryl sulfate 0.25–0.50 oz. and Wyoming bentonite 5 lb./100 gal. The schedule started with the 1st hatch of larvae and included 8 cover sprays, the last 4 with the nicotine sulfate and bentonite reduced to 0.67 pint and 3.3 lb., resp., per 100 gal. Na lauryl sulfate could be omitted from the formula if the pellet form of bentonite was used, although there was some evidence that its presence was helpful in maintaining a higher efficiency during long periods of weathering. The substitution of mineral oil 2 quarts, nicotine sulfate 0.67 pint and bentonite 1 lb./100 gal. for the standard tank-mixed spray in the 3 second-brood sprays eliminated the necessity for washing the fruit without seriously lowering the insecticidal efficiency. Late oil-nicotine sprays were most helpful in masking and softening the visible bentonite deposits on nonwaxy varieties of apples. Varieties that form considerable wax before harvesting may require washing with a soln. of 5% Na silicate and 0.5% oil in a brush machine. Trees sprayed with Pb arsenate retained at harvest 66% of the total deposit applied, with tank-mixed nicotine-bentonite 20%, with com. nicotine-bentonite 18% and with phenothiazine 11%. Nicotine treatments weakened more rapidly around the calyx end of the apple than did Pb arsenate treatments, because more of the early cover spray deposits were dissipated before late summer. K. D. Jacob

Substitutes for lead arsenate [for codling-moth control]. R. L. Webster. *Proc. Wash. State Hort. Assoc.* **33**, 111–17(1937).—A review of results obtained in Wash. State with nicotine, pyrethrum, rotenone, phenothiazine, F compds. and Ca arsenate. K. D. Jacob

The role of calcium hydroxide in preventing hydrogen sulfide from decomposing lead arsenate. J. M. Ginsburg and L. E. Perlgut. *J. Econ. Entomol.* **32**, 612–15(1939).—Small quantities of H_2S present in spray mixts. readily decomp. $PbHAsO_4$, releasing large amts. of sol. As (G. and P., *New Jersey Agr. Exptl. Sta. Bull.* **655**(1938)). The sources of the H_2S are many: spray water from stagnant pools and polluted wells; from the S fungicides used in arsenical sprays; from the action of certain org. reducing substances (glutathione) in leaf tissues and fungous spores on the S deposited on plants by fungicidal sprays. $Ca(OH)_2$ reacts directly with H_2S forming CaS. An excess of $Ca(OH)_2$ is necessary to prevent the decompn. of $PbHAsO_4$ by H_2S since CaS in low concns. itself tends to decomp. $PbHAsO_4$. C. H. Richardson

Tandem doses of calcium cyanide for controlling insects on plants. W. E. McCauley. *J. Econ. Entomol.* **32**, 729–30(1939).—In preliminary expts., chrysanthemum

plants and *Thrips nigropilosus* were fumigated with 0.5 oz. $Ca(CN)_2$ per 1000 cu. ft. for 1 hr.; then ventilated 3 hrs. and again treated with the same dose and exposure time. The results were encouraging. It is possible that resistant insects on tender plants can be controlled by the use of successive small doses of $Ca(CN)_2$ for short exposures with intervening periods of ventilation. C. H. R.

Fungicide investigations. W. H. Read. *Exptl. Research Sta., Turner's Hill, Herts, Ann. Rept.* **24**, 62–3 (1938) (Pub. 1939); cf. *C. A.* **32**, 8064[b].—A Cu Zn silicate (Cu 25, Zn 4%) when used at 0.2% concn. in combination with a petroleum oil emulsion gave good control of tomato leaf mold (*Cladosporium fulvum*) without noticeable marking of the foliage or fruit. Control of the mold by 0.2% Cu Zn silicate with a sol. wetting agent was not effective and left a more readily visible deposit than when used with an oil emulsion. K. D. Jacob

Comparisons of orchard fungicides, 1938 J. F. Hockey. *Ann. Rept. Nova Scotia Fruit Growers' Assoc.* **75**, 53–5, 57–8 (1938).—Results obtained with a wide variety of fungicides are summarized. K. D. Jacob

Comparisons of spray materials in 1937. J. F. Hockey. *Ann. Rept. Nova Scotia Fruit Growers' Assoc.* **74**, 73–8 (1937).—No injury to apple trees was caused by the addn. of borax to Bordeaux mixt. sprays at the rate 5 lb./100 gal. Although borax has no special virtue as a fungicide against apple scab, its use in standard Bordeaux sprays may be effective in overcoming B deficiencies in the trees. K. D. Jacob

Observations on the chemistry of sulfur sprays. J. L. St. John and Kermit Groves. *Proc. Wash. State Hort. Assoc.* **33**, 128–34 (1937).—A review, with 26 references. K. D. Jacob

Further experiments with inverted or "dynamite" spray mixtures [in codling-moth control]. James Marshall and Kermit Groves. *Proc. Wash. State Hort. Assoc.* **33** 119–27 (1937); cf. *C. A.* **33**, 5578[3,6].—Inversion of Pb arsenate mixts. was speeded up and the spray deposit improved in the early cover sprays by adding 0.5 oz. $ZnSO_4$ (23% Zn) per 100 gal. $ZnSO_4$ in amts. up to 3 oz. per 3 lb. Pb arsenate did not affect the toxicity of the latter. As much as 2 oz. $ZnSO_4$ per 100 gal was required to stabilize the last cover spray. Inverted sprays made from ZnO and oil were very effective in preventing the entrance of codling-moth larvae into apples but were not toxic to the worms. Sperm oil, peanut oil and cottonseed oil of certain specifications were satisfactory substitutes for herring oil in conjunction with kerosene and Pb arsenate to make certain types of inverted sprays and stove oil was an effective substitute for kerosene. Petroleum oils varying from 70 to 80% unsulfonatable residue, and of less than 70 sec. Saybolt viscosity, gave satisfactory results when used at 0.5% concn. in inverted Pb arsenate mixts. Monoethanolamine was superior to either triethanolamine or NH_3 as a base for use with oleic acid in prepg. inverted Pb arsenate sprays. Cryolite was successfully used as an inverted mixt. and it was possible to obtain a wide range of spray deposit with such mixts. K. D. Jacob

A method for testing the value of chemical mixtures as repellents of the Gulf Coast tick [Amblyomma maculatum Koch]. Arthur L. Brody. *U. S. Dept. Agr., Bur. Entomol. Plant Quarantine* **ET-152**, 4 pp. (Oct., 1939).—Definite nos. of male and female ticks are confined to the chemically treated ears of the animal by means of an adjustable headgear and 2 cylindrical cages held tightly in place, one over each ear. K. D. Jacob

Experiences with sulfonated oil. J. A. McClintock. *Trans. Indiana Hort. Soc.* **78**, 128–9 (1938) (Pub. 1939).—A satisfactory product for use in preventing rodents from attacking the trunks of young fruit trees was prepd. by heating raw linseed oil to 350°F. in a large container and slowly sifting into the hot oil 300-mesh S at the rate of 12 oz./gal. Effective combination of the S with the oil was obtained. K. D. Jacob

Cleansing chlorate-contaminated pots. O. Owen. *Exptl. Research Sta., Turner's Hill, Herts, Ann. Rept.* **24**, 88 (1938) (Pub. 1939).—**The chlorate was effectively removed by soaking the pots for 2 hrs. in a 5% soln. of** $Na_2S_2O_3.5H_2O$ and then rinsing with cold water. The cleaned pots produced no injurious effects, either from chlorate or from thiosulfate on plants grown therein. K. D. Jacob

Development and assimilation of nutrients by flax (Opitz) **11D.** Removal of nicotine-bentonite spray residues from apples at harvest (Fahey, *et al.*) **12.** Effect of recent increase in government Pb tolerance on spray practice (Burkholder) **12.** Compns. for destroying slugs and other pests (Brit. pat. 508,125) **13.** Fog or mist for plant protection (U. S. pat. 2,173,756) **13.** Product having insecticial and pest-destroying properties (Brit. pat. 508,407) **17.**

Fertilizers. Ottomar Weber. Brit. 508,127, June 27, 1939. A readily transportable fertilizer is obtained from sea slime or like slime-like masses that form in river estuaries, rivers, seas and ponds by dehydrating the slime into a pulp that is still sufficiently thin to flow and then mixing it with such quantities of nonabsorptive or slightly absorptive and finely grained substances, e. g., sand, ground granite, ground basic slag, that a loose mixt. is obtained that is easily penetrable by air.

Fertilizers. Kai Petersen. Brit. 508,145, June 27, 1939. A granular and pulverulent biol. composite fertilizer is obtained by subjecting household and town refuse and like solid waste materials to a mech. disintegration with simultaneous and (or) subsequent intermixing and sepn. of noncrushable components, subjecting the product so obtained to a temporary thermophile fermentation to kill the pathogenic bacteria present, admixing therewith a waste material aerobically biologically activated in the state of a pulpy mass and drying the product prior to, during or after the admixt. The aerobically activated waste material may be obtained by treating sewage sludge and nightsoil as described in Brit. 476,772 (*C. A.* **32**, 4271[8]).

Calcium metaphosphate fertilizer. Harry A. Curtis. U. S. 2,173,826, Sept. 26. A process of making Ca metaphosphate readily available as a fertilizer, from a Ca-contg. material such as rock phosphate, reactive with H_2PO_4 to produce mono-Ca phosphate, and H_3PO_4 involves making a mixt. of the fine Ca-contg. material and an aq. soln. contg. 30 to 45% of H_3PO_4, in substantially stoichiometrical proportion for the formation of mono-Ca phosphate; feeding the mixt. through a plurality of heated zones; maintaining the heated mixt. at an increasing temp. gradient up to 1000–1200° adapted successively to remove the free water from the mixt. and produce mono-Ca phosphate, to convert the mono-Ca phosphate into a metaphosphate, which is only partially available as a plant food, and to fuse the metaphosphate thereby making it entirely and readily available as a plant food and cooling the fused metaphosphate to solidify and maintain it readily available as plant food.

Insecticides. Walter C. O'Kane (to Spray Base Corp.). U. S. 2,172,689, Sept. 12; Brit. 507,902, June 16, 1939. An insecticidal concentrate suitable for prepg. sprays for use on foliage comprises a fixed oil such as corn oil together with a contact insecticide such as a pyrethrum extract and a volatile liquid such as turpentine in which the contact insecticide is sol. and which is itself sol. in the oil, and emulsifying agent such as "Emulphur A" which is sol. in the concentrate. U. S. 2,172,690, Sept. 12; Brit. 508,003, June 16, 1939, relates to generally similar insecticidal concentrates in which the oil used is a mineral oil.

Insecticides. Tiffany Lind (to Lin-Tox Corp.). U. S. 2,173,849, Sept. 26. Insecticides suitable for combating the Japanese beetle contain an aq. soln. of a soap of a drying oil fat acid such as the K soap of linseed oil fat acids (suitably together with about 0.007% of rotenone).

Insecticidal and fungicidal compositions. The Dow Chemical Co. Brit. 508,768, July 5, 1939. See U. S. 2,145,259 (*C. A.* **33**, 3516[9]).

Copper xanthates. Roscoe H. Carter (to the people of the U. S. A. for free use). U. S. 2,173,383, Sept. 19. **Details are given of the production of Cu xanthates of the**

monomethyl and monoethyl ethers of ethylene glycol (insecticidal and fungicidal compds.) and mention is made of the similar production of xanthates of the corresponding Pr, Bu and Am ethers of ethylene glycol. U. S. 2,173,384 relates to the production of corresponding Cu xanthates of alkyl ethers of diethylene glycol. The K xanthate is first formed and then made to react with $CuSO_4$.

Fumigating growing corn against insects. Geo. W. Barber (to the people of the U. S. A. for free use). U. S. 2,173,293, Sept. 19. Within the internal silks of each ear of corn there is inserted an insecticidal fumigant tablet, such as one of hexachloroethane, and the ear is sealed above the tablet so that the gases from the tablet are forced to flow between the ear and the surrounding husks.

Herbicide suitable for use along roads, etc. Harold R. Offord (to the people of the U. S. for free use). U. S. 2,173,236, Sept. 19. "Technical" furfural satd. with a "technical" grade of NH_4CNS is used with an equal or larger proportion of Diesel oil of 27–32°Bé., and this mixt. is applied as a spray or soil drench.

Weed-killing compositions. Chipman Chemical Co. Ltd. Brit. 507,514, June 16, 1939. These consist of a mixt. of a chlorate of a metal of the alkali or alk. earth group, an alkali or alk. earth salt of an aliphatic carboxylic acid having not more than 4 C atoms in the mol., e. g., HCOOH, AcOH, butyric acid, and $CaCl_2$ or $MgCl_2$. The org. acid salt preferably has a metal ion in common with the chlorate. A preferred compn. consists of $NaClO_3$, AcONa and $CaCl_2$.

Weed killer. I. G. Farbenind. A.-G. Ger. 679,862, Aug. 15, 1939 (Cl. 45*l*. 5). In using chlorate soln., especially $NaClO_3$ soln., as a weed killer, fire-preventing substances such as $CaCl_2$ or $MgCl_2$ are also added to the soln.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Manufacture of alcohol from Jerusalem artichoke. IV. Alcohol fermentation of the rhizome of Jerusalem artichoke. 1. Tosinobu Asai. *J. Agr. Chem. Soc. Japan* **14**, 545–64(1938); cf. *C. A.* **32**, 1041⁵.—The hydrolysis of the rhizome was most favorable when the rhizome was heated with 0.5% H_2SO_4 or 0.3% HCl under 40 lb. at 139–41°. The hydrolyzate was fermented by alc. yeast M 1 for 70 hrs. The yield of alc. was 82.3%. **VIII. Influence of the storage of the rhizome on alcohol fermentation.** Tosinobu Asai and Susumu Kikuti *Ibid.* **15**, 33-42(1939); cf. *C. A.* **33**, 5979⁷.—During the storage underground, the contents of H_2O and reducing sugar gradually increased while those of total sugar, nonreducing sugar, N and ash decreased. The pH was changed from 6.5 to 5.9. In the earlier stage the carbohydrates sol. in cold H_2O decreased and the nonreducing sugar increased, while in the latter stage the amt. of reducing sugar increased. There was not a large decrease in carbohydrates sol. in hot H_2O during storage. There was a large decrease in nonprotein N content. The fermentation ratio by *Schizosaccharomyces pombe* was equal at every period of storage. The rhizome was easily dried without any loss. There was no difference in fermentation ratio between the air-dried rhizome and the one dried by heat. **IX. Alcohol fermentation of the rhizome of Jerusalem artichoke. 4.** *Ibid.* 115–27.—When the fresh rhizome was heated with 0.05–0.2% HCl at 100–20° for 1 hr., no loss in sugars was observed. The amino N content decreased with the concn. of acid and the temp. When the rhizome was steamed and directly fermented, 9.97 l. of alc. was obtained from 100 kg. of the fresh rhizome. **X. Alcohol fermentation of the rhizome of Jerusalem artichoke. 5.** *Ibid.* 563–74; *Bull. Agr. Chem. Soc. Japan* **15**, 102–3(in English).—In the direct fermentation the addn. of peptone increased the fermentation ratio, while that of $(NH_4)_2SO_4$, soybean cake, rice bran or fish-oil cake had no effect. When 0.01–0.02% of peptone was added to the mash as a N source, it was most suitable. The effect of the addn. of K_2PO_4 was not great. When the alc. yeast no. 35 was used with *Schizosaccharomyces pombe*, the beginning of fermentation was accelerated and the *fermentation* ratio was also increased. The prepn. of the mash by the diffusion method was recommended as the carbohydrates were completely extd. with hot H_2O. Y. Kihara

Alcoholic fermentation at Chateauneuf-du-Pape. Gaston Mathieu. *Compt. rend. acad. agr. France* **25**, 500–3 (1939); cf. *C. A.* **32**, 7203⁹.—A secondary fermentation caused a 40% decrease in the volatile acid content of a wine. J. R. Adams

β-Hydroxyglutamic acid in soy sauce. Yukio Tomiyasu. *J. Agr. Chem. Soc. Japan* **15**, 871–5; *Bull. Agr. Chem. Soc. Japan* **15**, 133–4(in German)(1939).—The concd. soy was treated with basic lead acetate and then phosphotungstic acid in dil. H_2SO_4 soln. The ppt. by phosphotungstic acid was filtered and the filtrate was neutralized with $Ba(OH)_2$. The ppt. of $BaSO_4$ was eluted with 1% HCl. The soln. was evapd. and alc. was added to sep. the Ba amino dicarboxylate. From the alc.-insol. part glutamic acid-HCl was removed by satg. with dry HCl gas. The filtrate was evapd. to a sirup and then oxidized with chloramine T. *p*-Nitrophenylosazone m. 298° was prepd. from the oxidation product. It was identified as *p*-nitrophenylosazone of malic semialdehyde. Hence β-hydroxyglutamic acid may be present in the soy sauce. Y. Kihara

Denatured and fuel alcohol. C. Mariller. *Bull. assoc. chim.* **56**, 600–6(1939).—Alc. used as household or motor fuel, and also the denaturants employed should be free from corrosive impurities, notably acids, esters, SO_2 and other S compds.; it should not be colored with dyestuffs contg. NaCl. F. W. Zerban

Amino nitrogen and amido nitrogen in Bordeaux wines. E. Peynaud. *Ann. fals.* **32**, 228–43(1939).—The methods used for the analyses are described and discussed. Analysis of 35 red and 36 white Bordeaux wines of known purity and good quality gave the following max., min. and av. values (in mg. per l.): total N 143–666 (330), 77–377 (185); ammonia N 1–71 (17.9), 0–14 (5); amino N 41–131 (80), 10–67 (33.6); amido N 1.4–5.6 (3.48), 1.1–3.3 (2.6); amino N as percentage of org. N 18.6–42.2 (26.4), 9.8–26.2 (18.3); amido N as percentage of org. N 0.6–2.3 (1.2), 0.6–5.1 (1.7). The results are discussed. A. Papineau-Couture

Rapid determination of the esters of volatile fatty acids (in wine). L. E. Grandchamp and J. Vollaire-Salva. *Ann. fals.* **32**, 244–7(1939).—Det. the volatile acidity of the wine by the French official (steam-distn.) method. Neutralize a second 10-cc. portion of wine with *N* NaOH and add 2 cc. in excess, let stand 1 hr. at about 20°, acidify with 10 drops of H_3PO_4, distil as in the official volatile acidity detn. and titrate the distillate. The difference in volatile acidity of the wine as such and sapond. is a measure of the volatile fatty acid esters, which are expressed as EtOAc. A. Papineau-Couture

Polarographic method for determining SO_2 in wine must. M. Salvarezza. *Ann. chim. applicata* **29**, 345–50 (1939).—The active SO_2 can be detd. by electrometric titration, the e. m. f. changing rapidly when the value of the reduction potential of the SO_2 present is reached. A. W. Contieri

Determination of acetic ester in deteriorated wines that are unfit for consumption. P. Archinard. *Ann. fals.* **32**, 254–60(1939).—The following method is a modification of that of Peynaud (*C. A.* **32**, 7659⁶): neutralize 50 cc. of wine to litmus, add 25 cc. of Peynaud's buffer soln. (25 g. K_2HPO_4 and 50 cc. *N* NaOH per l.), distil 15 cc., collecting in a 50-cc. volumetric flask contg. 20 cc. 0.1 *N* NaOH and 15 cc. H_2O, stopper the receiving flask, heat 15 min. in a water bath at 50°, transfer to an

Erlenmeyer flask, add exactly 20 cc. 0.1 *N* H_2SO_4 (to neutralize the NaOH), boil for about 30 sec., cool and titrate with 0.05 *N* NaOH in presence of phenolphthalein. Results are given to show that acidity is not a reliable criterion of the sourness of wine, and that in this respect the EtOAc content is in much better agreement with organoleptic tests. A. Papineau-Couture

Potato drying. Varinois. *Bull. assoc. chim.* **56**, 631–40(1939).—Drying of potatoes makes it possible to prevent deterioration and to utilize them as raw material for beet distilleries during the off-season. Two drying systems are described. F. W. Zerban

[Report of] molasses laboratory. A. R. Lamb. *Proc. Hawaiian Sugar Planters' Assoc., Rept. Comm. in Charge Expt. Sta.* **58**, 116–17(1938)(Pub. 1939); cf. *C. A.* **32**, 6394⁷.—A process has been developed for the production of dried *yeast* from final molasses, the yeast to be used for human or animal food. A lactic acid organism has been isolated which grows well in molasses solutions, and produces only *d*-lactic acid. A. R. Lamb

Enzymes in rice malt (Munakata) **11A.** Changes in fat and theobromine content of the kernel of the cacao bean during fermentation (Humphries) **27.** App. for taking samples of beer and for transporting the app. in a sterile condition (Brit. pat, 508,585) **1.** App. for producing a pulsating circulation of liquids contg. gas-evolving products, as in fermenting grape must (U. S. pat. 2,174,203) **1.**

Citric acid. Walter K. Lorenz. Ger. 679,847, Aug. 15, 1939 (Cl. 6*b*. 16.02). Nutritive solns. contg. growth-promoting substances, such as molasses or milk, are treated with vitamin-destroying substances such as peroxides, nascent O, catalytically excited H or lyes, and acid is added to produce an optimum H-ion concn. for fermentation of the liquor by mold fungus, to produce citric acid. Examples are given.

Clarifying wine, etc. I. G. Farbenind. A.-G. (Engelbert Sailer, inventor). Ger. 679,969, Aug. 18, 1939 (Cl. 6*c*. 1). Wine, beer, etc., is clarified by heating with an absorption agent such as Fe_2O_3 at 40–50°.

Apparatus and method for supplying wort to a fermentation vat. Svenska Jästfabriks Aktiebolaget. Brit. 507,608, June 19, 1939.

Beer wort. Gottfried Jakob. Ger. 676,328, June 1, 1939 (Cl. 6*b*. 14). Addn. to 626,535 (*C. A.* **30**, 5722¹). A method of filtering hot wort by first filtering through spent hops or malt, or pumice, and then through a fine filter mesh, is described.

17—PHARMACEUTICALS, COSMETICS AND PERFUMES

W. O. EMERY

Pseudocinchona africana A. Chev., its chemical composition and therapeutic utilization. Raymond-Hamet. *Rev. botan. appl. agr. trop.* **19**, 564–9(1939).—Chem. analysis differentiates between *Pseudocinchona* and *Corynanthe paniculata*. The former contains both corynaphine and corynantheine while the latter contains yohimbine. Corynanthine has a very marked aphrodisiac action and it appears that *Pseudocinchona africana* has very marked therapeutic value. J. R. Adams

Investigation on the vitamin content in oil of sticklebacks (Gasterosteus). Ruth Wegelius. *Nord. Med.* **3**, 2716(1939).—Vitamin A was detd. biologically and colorimetrically, vitamin D biologically. The oil showed no biol. vitamin A potency. Colorimetrically a value of 50 I. U. per g. was found. The amt. of vitamin D in the oil was 50 to 100 I. U. per g., corresponding to an av. fish-liver oil. V. Aschehoug

The determination of phenols in essential oils. F. D. Dodge. *Am. Perfumer* **39**, No. 4, 35–6(1939).—The detn. of phenols in oils by alk. extn. is unsatisfactory especially for oils of low phenol content because of their variation in acid strength. The following method is fairly accurate especially for oils contg. up to 30% phenol. Thirty cc. *N* $NH_2C_6H_4SO_3Na$ (or K) (slight excess to prevent the presence of free HNO_2) in a 250-cc. flask of the cassia-oil type with neck graduated 10 cc. in tenths is chilled in ice and treated with 25 cc. *N* HCl and 25 cc. *N* $NaNO_2$ (or KNO_2). After 30 min., 10 cc. of oil (note temp.) and four 25-cc. portions of *N* NaOH are added and shaking is continued 30 min. at 0°. The phenol present reacts with the diazosulfanilic acid formed to give a sulfonic acid which will dissolve quantitatively in the alk. soln. The flask is filled with *N* NaOH and allowed to return to normal temp. For thymol mixts. the nonphenol usually seps. clearly and the vol. may be read off. For eugenol mixts. the results are not satisfactory because of the sepn. of an insol. by-product. If some oil sticks to the flask, most of the oil can be removed by a pipet, the soln. decanted into a 2nd flask and the 1st flask washed with a few drops of Me_2CO which is dissolved on shaking and the recovered oil estd. A separatory funnel may be used. Janet E. Austin

Native poisons and native medicines of Tanganyika. W. D. Raymond. *J. Trop. Med. Hyg.* **42**, 295–303 (1939).—A review with 44 references. R. Brown

Pectin. M. A. Lesser. *Drug Cosmetic Ind.* **45**, 549–51, 554(1939).—The therapeutic applications of this substance are reviewed. Two formulas for hair pomades and one for a tooth paste are offered. 29 references. H. M. Burlage

Cosmetic manual. Vanishing creams. Joseph Kalish. *Drug Cosmetic Ind.* **45**, 555–6, 561(1939); cf. *C. A.* **33**, 8911⁶.—These creams may be of the liquefying type which do not contain H_2O and of the emulsified type contg. a large proportion of mineral oil. Products contg. emollients (27 formulas) and products of the cold-cream (14), lanolin (14) and vanishing-cream types (13) are discussed. H. M. Burlage

East Africa and its aromatic plants. Alfons M. Burger. *Riechstoff Ind. Kosmetik* **14**, 153–8(1939); cf. *C. A.* **33**, 5121⁸.—The oils of *Aframomum mala* K. Schum (leaves, seeds and rind), *A. amaniense* Loes. (leaves and seeds), *Cinchona* species, *Coleus*, *Conopharyngia holstii* Stapf, *Cymbopogon afronardus*, *Eucalyptus citridora* Hook, *Geranium*, *Pelargonium radula* (rosea), *P. capitatum*, a *Zanthoxylum* species, *Brachylaena hutchinsii*, *Hoslundia opposita*, *Ocimum menthaefolium* Hochst. and its other species, *Ocotea usambarensis* Engl. and mawah are discussed including their chem. and phys. constants. H. M. Burlage

Peru balsam. Karl Dopf. *Riechstoff Ind. Kosmetik* **14**, 159–62(1939).—A discussion. H. M. B.

Care of the hands. Hugo Janistyn. *Riechstoff Ind. Kosmetik* **14**, 163–6(1939); cf. *C. A.* **33**, 8911⁶.—The following prepns. are discussed: modern Swedish glycerols (3 formulas), a glycerol jelly with the aid of gelatin, one with pectin, a citroglycerol, a cream with glycerol and starch, one with a stearate base for the hands, one with a base of glycerol and stearate, one with a base of triisopropanolamine, a cream for whitening the hands, an acid cream for the hands, a mother-of-pearl liquid cream, a hand massage cream, a cream with a lanolin base of superior quality, a liquid hand cream, two hand lotion creams, two with absorption bases, a cream with a base of propylene glycol monostearate, a nail polisher and nail lacquers. *Ibid.* 175–7(1939)(in French).—Formulas (21) are offered for nail varnishes, varnish removers, cuticle removers, cuticle oil, special creams for brittle and stiff nails, polishing agents (powders, creams and sticks), white (nail and moon), bleaches and a balm for injured nails. H. M. B.

The use of vitamins and hormones for the production of biologically active cosmetic products. W. Rehdern. *Riechstoff Ind. Kosmetik* **14**, 171–4(1939); cf. *C. A.* **33**,

9547. Vitamins and hormones are discussed and formulas (6) with detailed procedures are offered for the following types of creams: hormone breast creams, vitamin skin vanishing creams, hormone creams (solid and liquid), a vitamin face lotion and milk. H. M. B.

A reaction for the distinction of procaine and larocaine as well as the detection of pantocaine. F. Biedebach and H. Weigand. *Scientia Pharm.* **10**, 140(1939).—Dissolve 0.01 g. of the substance in 30 drops of H_2O, add 1 drop $NaNO_2$ soln. (1:10) and a drop of 2.5% HCl and immediately 20 drops of 2% C_6H_5OH in H_2O. An orange-red color appears at once in the liquid. With procaine (*A*) small shiny golden-yellow leaflets begin to form at once; with larocaine (*B*) they appear only after 10 min. Crystals with *B* appear as yellow bundles of numerous needles which begin to decomp. with discoloration and the evolution of gas at 120° while those of *A* appear as small flat leaves of irregular outlines, are colorless and begin to decomp. at 150°. With *tutocaine* (*C*) no crystals appear even upon long standing. The deriv. of *A* was found to be an azo dye: *p*-$HOC_6H_4N.NC_6H_4$-*p*-$CO_2C_2H_4NEt_2$-*p*. For the identification of pantocaine (*D*) dissolve a small amt. in a small drop of H_2O and add a drop of $NaNO_2$ soln. and a mass of long colorless needles often with notched ends appears. The same test was applied to *A*, *B*, *C*, cocaine, nupercaine, psicaine and only psicaine gives upon the addn. of much reagent an oily sepn. which did not solidify on long standing. The compd. with *D* possesses the characteristic anesthetic action of *D*, m. 104–5°, soly. in H_2O (1:80) and its soly. is strongly lowered by an excess of nitrite indicating that the nitrite of *D* is formed, $C_{16}H_{24}O_2N_2.HNO_2$. H. M. Burlage

The examination of homeopathetic preparations with dithizone. B. Bleyer, G. Nagel and J. Schwaibold. *Scientia Pharm.* **10**, 121–4(1939). A simple method for the qual. and quant. testing of homeopathetic heavy metals including Cu, Ag, Hg, Zn, Pb, Cd, Bi, Au and Co is outlined and the results obtained with 18 com. products—9 dilns. and 9 triturations are tabulated. It is established that in the manuf. of higher dilns. there is many times a diminution and occasionally a complete disappearance of the content of the active constituent. H. M. Burlage

Most important drugs occurring in European trade, their identification, adulteration and use. Franz Berger. *Scientia Pharm.* **10**, 140–4(1939); cf. *C. A.* **33**, 5988[8].—The following drugs were studied and their pharmacognostic features and tests described: (1) Jalap root which should have an ash of 6.5% (max.), ether-sol. portion 1.2%, resin portion at least 10%. Adulterants include *Ipomoea orizabensis* Ledan, *I. simulans* Hanbury and *I. operculata* Mart., (2) the root of *Cymbopogon iwarancusa* Schult (*Andropogon iwarancusa* Jones), which contains 0.4–0.9% volatile oil, resin and bitter principle, (3) root of kava-kava, (4) radix *Lapathi acuti* coming from *Rumex obtusifolius* L. and *R. crispus* L., (5) the root (rhizome) of *Levisticum officinale* Koch which contains 0.6–1% volatile oil, sugar, starch, gum and an acid, (6) licorice root of which 3 trade varieties are described: Russian, Spanish and Asia Minor, (7) the root of *Meum athamanticum* Jacq. contg. 0.76% volatile oil, resin, gum, starch, fatty oil and wax. H. M. B.

History and nomenclature of celandine. Karl Daniel. *Wien. Pharm. Wochschr.* **72**, 522–4(1939). H. M. B.

Bactericidal action in vitro of gold thioglucose and gold calcium keratinate on homogenous cultures of human tubercle bacillus. P. Pichat. *Compt. rend. soc. biol.* **132**, 13–14(1939).—Au thioglucose (50% Au) was bactericidal in concns. of $^1/_{10,000}$–$^1/_{1,000,000}$ and Au Ca keratinate (14% Au) in concns. of $^1/_{5000}$–$^1/_{250,000}$. Both higher and lower concns. than the above were not bactericidal. L. E. Gilson

The comparative activity of desoxycorticosterone and other crystalline derivatives and of purified extracts of the adrenal cortex. Arthur Grollman. *J. Pharmacol.* **67**, 257–64(1939).—Synthetic desoxycorticosterone acetate has an activity of one rat unit per mg. when assayed on the immature adrenalectomized rat. Its use as a standard reference substance for the assay of adrenal cortical exts. is suggested. It is quite effective when given orally. In some minor respects its action is not identical with that of cortical ext. Corticosterone is comparatively inactive. A simple method is described for prepg. a potent adrenal-cortical ext. A cryst. steroid (cf. *C. A.* **32**, 8530[6]) has been isolated from the ext., the comparatively high potency of which suggests it to be the true cortical hormone. Several other cryst. compds. isolated from adrenal exts. were inactive. L. E. Gilson

Stabilization of easily oxidized drugs. L. Donatelli. *Boll. soc. ital. biol. sper.* **14**, 429–32(1939).—Adrenaline solns. were rendered stable without affecting their properties by the addn. of ascorbic acid, Na ascorbate, sucrose and Me *p*-hydroxybenzoate. H. L. Gruehl

Extract of malt with cod-liver oil. Determination of oil and vitamin A. D. C. Garratt. *Analyst* **64**, 795–806(1939).—The detn. of the oil content and of the vitamins is of considerable importance to buyers o this pharmaceutical prepn. The present paper is concerned with the extn. of the oil from the emulsion and secondly the suitability of the extd. oil for the vitamin A detn. Seven different methods for extg. the oil were studied and the most satisfactory procedures were those of Rose-Gottlieb and of Gunn and Venables (*C. A.* **31**, 808[7]) For fresh prepns. both methods gave satisfactory but with older prepns. the method of G. and V. gave lower values. Objection to this last statement was raised in the discussion of the paper. The vitamin A content of the extd. oil was detd. spectrophotometrically and corresponding values were obtained by the Rose-Gottlieb method. It is recommended, therefore, in the assay of *Extract of Malt with Cod-Liver Oil* and of vitamin A in the extd oil, to make use of the Rose-Gottlieb method modified by the use of the centrifuge and with precautions to prevent oxidation. W. T. H.

A new method for estimating total alkaloids in cacao. E. C. Humphries. *Ann. Rept. Cacao Research* **8**, 36–7 (1938)(Pub. 1939). Mix 5 g. fat-free cacao powder with 2.5 g. freshly calcined MgO and add about 10 cc. water dropwise until all the particles are wetted. Partially dry the mixt. by heating in a porcelain dish on the water bath for about 0.5 hr. Mix the residue thoroughly, wrap in a No. 41 Whatman filter paper, place in an extn. thimble and ext. in a Soxhlet app. with $CHCl_3$ for 20 hrs. Evap. the solvent and dry the residue at 100°. Allow the residue, which contains the alkaloids and some fatty material, to stand overnight in 100 cc. petr. ether, collect the insol. material in a tared Gooch crucible, dry at 100° and weigh. Remove the caffeine by allowing the dried residue to stand for a few hrs. in 100 cc. benzene, collect the solid residue (theobromine) in an asbestos-lined Gooch crucible and weigh. The precision of the method is good and a 20-hr. extn. is sufficient to remove all the alkaloids from the powder. The method gave results for theobromine and caffeine in cacao powders from different varieties of beans as follows: Criollo (variety V_0) 2.15 2.31, 0.90–1.05; Criollo (variety 48) 1.05–1.23, 0.51–0.99; good Forastero 2.46, 0.24; and Calabacillo 2.85–2.90, 0.71–0.74%, resp. K. D. J.

A critical investigation of the tetrachloroethane extraction method for determining theobromine in cacao. E. C. Humphries. *Ann. Rept. Cacao Research* **8**, 38–9 (1938)(Pub. 1939).—The relative merits of the Wadsworth (*C. A.* **15**, 1170) and McDonald (*C. A.* **32**, 969[8]) methods were investigated and the latter was found to be more satisfactory. MgO is not essential for mixing with the fat-free powder when $C_2H_2Cl_4$ is used as solvent. K. D. Jacob

The alkaloids of the cortex of Aspidosperma quebracho-blanco. Rafael A. Labriola. *Anales asoc. quim. argentina* **27**, 150–9(1939).—Aspidospermine, quebrachine (yohimbine), quebrachamine, aspidospermatine and hypoquebrachine were studied. E. M. S.

Strong solution of ammonium acetate, Brit. Pharm. 1932. R. D. Kotwal. *Pharm. J.* **142**, 276(1939).—To obtain a prepn. of required strength when the NH_4

carbonate (*A*) prescribed is below standard, put 400 g. of *A* (i. e., 70 g. in excess) into a wide-mouthed bottle, add 350 ml. H_2O and 453 g. AcOH in small portions without stirring. After the reaction has subsided, e. g., after 2 hrs., shake occasionally and set aside for 12 hrs. When a residue of *A* is left, decant the mixt. and add to the liquid a sufficient quantity of strong NH_3 soln. as directed by the Pharm. If, however, all *A* is dissolved, add about 20 g. more *A* and shake the mixt. to insure a residue of *A* before decanting and adding NH_4OH to finish the prepn. S. Waldbott

Isotonic solutions. E. J. Schorn. *Pharm. J.* **142**, 383–4(1939).—The difficulties in precalcg. isotonicity of a soln. are pointed out. The method of Wokes (cf. *C. A.* **31**, 809[2]) based on the effect of the finished injection on red blood cells is recommended. H. Treves Brown. *Ibid.* 452.—Since in the Wokes method the ratio of hemolyzing to isotonic concn. varies for different substances from about 2 to 3.2, calcns. of isotonicity by this method might introduce grave errors, much larger than those resulting from the Brit. Pharm. Codex method, which is recommended. In support, the Swiss Pharm. V statement is quoted that for solns. not very far removed from 1%, the depression is, as a rule, very closely proportional to the concn.; any error caused by the divergence is physiologically insignificant. S. Waldbott

---

Changes in fat and theobromine content of the kernel of the cacao bean (Humphries) **27**. New machines and app. for the cosmetic industry (Meyer) **27**. Anemia, and deterioration of ferrous sulfate and ascorbic acid solns. (Tomski, Waller) **11G**. Identification of the Columbian plant pinic-pinic (Janot, Mendoza) **11D**. Alkylolamine derivs. [for use in cosmetic creams] (U. S. pat. 2,173,448) **13**. Sulfones [intermediates for the manuf. of pharmaceutical products] (Brit. pat. 507,378) **25**.

Therapeutic preparations. Johannes Heller. Brit. 508,149, June 27, 1939. The prepns. are made from chlorophyll-contg. plants by irradiation of the plant substance with ultraviolet light for 3–4 hrs. at below 0°, followed by drying at above 0° and below 40° with exclusion of daylight.

Therapeutic cysteine hydrochloride compositions. Ferdinand W. Nitardy (to E. R. Squibb & Sons). U. S. 2,174,009, Sept. 26. Stable, noncaking prepns. suitable for dispensing in ampoules and for use with water in treating open wounds contain cysteine-HCl together with a buffering agent such as borax, Na citrate or Na phosphate to give the aq. soln. a pH between 3 and 5 (preferably between 3.5 and 4).

Emulsions; medicinal preparations. Garth W. Boericke and Wm. W. Young. Brit. 508,288, June 28, 1939. A fat sol is prepd. by agitating a fat with EtOH, mixing with approx. 3 times its vol. of distd. H_2O, expelling all but a small proportion of the EtOH by heat and filtering the emulsion. Wool fat is preferred, and glucose may be added. Kekuni nut and lecithin sol may be used. Phosphates, sulfates and $CaCO_3$ may be added to the sols. The sol, the colloidal particles of which are substantially 1 μ in size, is used as a detoxicant therapeutically, either subcutaneously or intravenously.

Lactation-stimulating preparations. Abraham Herschel. Brit. 507,825, June 21, 1939. These consist of a mixt. of isoleucine and cystine or the physiologically equiv. substances, cysteine, glutathione, methionine, etc. The compds. are advantageously admixed with edible oils, e. g., wheat-germ or cod-liver oil.

Triethanolamine salts. Fritz E. E. Stockelbach. Brit. 508,818, July 6, 1939. The triethanolamine salt of *o*-cresotic acid is prepd. by causing the amine to react with about an equimol. proportion of the acid, suitably at 100°. The triethanolamine salt of 2,3-hydroxynaphthoic acid is prepd. similarly. The salts absorb ultraviolet light and may be used for prepg. cosmetic creams and lotions for preventing sunburn and for promoting tan pigmentation of the skin.

Phytyl bromides. F. Hoffmann-La Roche & Co. A.-G. Brit. 508,292, June 28, 1939. See Swiss 203,-135 (*C. A.* **33**, 9553[9]).

Heavy-metal compounds of sulfhydryl keratinic acid. Ernst Sturm and Richard Fleischmann (to Firma Johann A. Wülfing). U. S. 2,172,717, Sept. 12. Various examples with details are given of a process for prepg. chemotherapeutic compds. derived from keratin which are rich in heavy metal, consisting in hydrolyzing keratin material with acid at least to the stage of formation of a gelatinous product, reducing the product with a metal, freeing the reduced product from metal, treating the product with a sol. salt of Au, Ag, Hg, Cu, Pb, Sb, Sn, Zn or Fe, the quantity of metal used being at least about double that necessary for satg. the sulfhydryl groups of the keratin degradation product, neutralizing the mixt. with alkali and filtering off any deposit which may form as a result of the neutralization, introducing the soln. into an org. solvent, and sepg. the compd. rich in heavy metal which is deposited.

Artificial peppermint oil. Dr. Hittel G. m. b. H. Brit. 507,257, June 13, 1939. A compn. of similar flavor and smell to peppermint oil consists of a mixt. of synthetic menthol (I), menthone (II), menthyl acetate (III) and menthyl isovalerate, e. g., in the proportions of 50, 35, 12 and 3%, resp. There may be added 3–5% of the initial and final fractions obtained from com. peppermint oil, eucalyptus oil, mint oil and similar oils, which improve the flavor. The ingredients of the compn. may be made by (1) partially hydrogenating thymol to form a mixt. of I and II, which is then treated with a restricted amt. of glacial AcOH to convert part of the I into III, the mixt. being then distd. to obtain fractions rich in II and III, (2) hydrogenating piperitone in the presence of Ni to form II and some iso-II, which is allowed to remain in the compn.; a part of this mixt. is removed and the remainder further hydrogenated and heated to 180° to form I as described in Brit. 238,314 (*C. A.* **20**, 2049); part of the I is heated with Ac_2O and isovaleric acid to form the esters. The products obtained are then mixed, together with the initial distillate from Japanese peppermint oil.

Vitamin B_1. Karl Merck, Louis Merck, Wilhelm Merck and Fritz Merck (trading as Firma E. Merck). Brit. 507,918, June 22, 1939. See Ger. 669,187 (*C. A.* **33**, 2657[1]).

Vitamin concentrates from materials such as tuna-liver oil. Nicholas A. Milas (to Research Corp.). U. S. 2,173,629, Sept. 19. App. is described, and a process for the extn., concn. and fractional sepn. of the vitamin A and D contents of naturally occurring substances which comprises saponifying the saponifiable constituents thereof, sepg. the unsaponifiable portion by extn. using a selective solvent, sepg. the phosphatide content of the unsaponifiable portion by selective solvent action, subjecting the remainder of the unsaponifiable portion comprising vitamins A and D together with sterols and other inert materials to a systematic fractionation which comprises progressively cooling and fractionally crystg. and filtering at successively lower temps. a soln. thereof thereby sepg. a soln. of vitamin A in substantially pure form from a series of residues contg. vitamin D, vitamin A, sterols and other inert materials, redissolving and recrystg. and filtering the residues in sequence including discarding the residue from the highest temp. crystn., thereby sepg. a second series of residues from a soln. of substantially pure vitamin A, repeating the redissolving, recrystg. and filtering sequence upon the residues in a plurality of series whereby to dissolve from the residues substantially all the vitamin A and to purify the same by low-temp. crystn. to sep. from the residues substantially all the sterols and other inert materials by discarding the residue from the highest temp. crystn. in each series, leaving the final residues as substantially pure vitamin D.

Hormones. Chemische Fabrik Promonta G. m. b. H. Brit. 508,453, June 30, 1939. See Ger. 677,844 (*C. A.* **33**, 9555[1]).

Cortical hormones. Soc. pour l'ind. chim. à Bâle.

Brit. 508,024, June 23, 1939. Hormone compds. are prepd. by treating compds. of the cortical hormone series, except those designated as Fa, M, C and D (see abstr. from *Helv. Chem. Acta* in *C. A.* **32**, 5792), with esterifying or etherifying agents. Esterification may be conducted with an acid, an anhydride, halide or ester thereof or with a ketone. Etherification is conducted in the usual manner and aryl, aralkyl or alkyl residues may be introduced. Esterification or etherification is preferably conducted in the presence of an acid-binding agent, e. g., pyridine, dimethylaniline or a trialkylamine, or an alkali carbonate. In the processes, the 21-OH group always enters into reaction. Under more energetic conditions, derivs. may be obtained of compds. of this series contg. more than 1 OH group or even of the enolic form of keto groups. The invention may be applied to the purification of compds. of the said series by forming derivs. by the process of the invention, purifying the derivs. by distn. and then regenerating the starting material. Compds. that may be used as starting materials have a ketol grouping in the 17-position, e. g., Δ^4-21-hydroxypregnene-3,20-dione, Δ^4-11,21-dihydroxypregnene-3,20-dione, Δ^4-11-keto-21-hydroxypregnene-3,20-dione and Δ^4-17,21-dihydroxypregnene-3,20-dione. Among examples, corticosterone is treated with Ac_2O in the presence of pyridine for a long time at room temp. to give corticosterone acetate.

Sex hormones. Schering A.-G. Brit. 506,859, June 6, 1939. A 17-alc. of the cyclopentanopolyhydrophenanthrene series of low physiol. activity is oxidized to the corresponding ketone and then reduced to give a mixt. of *cis*- and *trans*-17-ales., from which the isomer of high physiol. activity is isolated. Among examples, (1) a *cis-trans*-estradiol mixt. is benzoylated, oxidized with CrO_3 in glacial AcOH and then reduced according to Brit. 449,461 (*C. A.* **30**, 8533[7]), (2) androstene-3-*trans*-17-*cis*-diol (I) is oxidized with Al isopropylate in anhyd. cyclohexanone and reduced as in (1), (3) I is oxidized by CrO_3 with intermediate protection of the nuclear double link by Br and then reduced as in (1).

Sex hormones. Schering A.-G. Brit. 508,305, June 26, 1939. Addn. to 445,189 (*C. A.* **30**, 6514[4]). The process of 445,189 for the production of pregnenediones by the oxidation of pregnenolones is modified by the use of isopregnenolone (I) as starting material, the product being pregnenedione of formula $C_{21}H_{30}O_2$, which is the corpus-luteum hormone. The oxidation is preferably conducted with intermediate protection of the nuclear double bond by a halogen, e. g., Br, or a H halide, e. g., HCl; in the latter case, the removal of the H halide after the oxidation can be effected by pyridine bases, alkali acetates in alc. soln. or other alk.-acting agents, while in the former, the halogen can be removed by Zn dust in acid or neutral soln., by treatment with NaI in Me_2CO according to the method of Finkelstein, careful hydrogenation in the presence of catalysts, e. g., Pt, Ni or basic reagents. In an example, I obtained by the isomerization of pregnenolone with methyl alc. KOH is oxidized at room temp. with CrO_3, with intermediate protection of the nuclear double bond by Br, which is subsequently removed by Zn dust in glacial AcOH, the progesterone being isolated by Et_2O extn.

Monoformate of androstenediol. Leopold Ruzicka, Albert Wettstein and Hans Kaegi (to Soc. pour l'ind. chim. à Bâle). U. S. 2,173,425, Sept. 19. The monoformate of androstenediol is produced by reducing the keto group of the formate of dehydroandrosterone to a carbinol group with H in the presence of a nonnoble hydrogenating metal catalyst such as Ni or Co in a neutral medium such as an aliphatic alc. of low mol. wt. Various examples of similar reactions also are given, for the production of therapeutic compds. active in the testing of sexual activity.

Sexual hormone products. Karl Miescher and Albert Wettstein (to Soc. pour l'ind. chim. à Bâle). U. S. 2,173,337, Sept. 19. Prepns. for parenteral use having enhanced sexual hormone action are obtained by combining testosterone, androstanediol, androstenediol, 17-methyltestosterone, estrone, estradiol or androstenedione with an aliphatic carboxylic acid, aliphatic hydroxy carboxylic acid or aliphatic alc. Numerous examples are given.

Gonad-stimulating product. Hubert R. Catchpole and William R. Lyons (Lyons to Hubert R. Catchpole). U. S. 2,173,353, Sept. 19. A product capable of stimulating and developing the gonads of males and females and sufficiently free from allergic-reaction-producing substances to be suitable for human use is derived from the placenta of a mare obtained between the 37th and 130th day of gestation, by extraction with acetone contg. NH_3, etc.

Immunizing vaccine for treatment of range paralysis or leucemia in poultry. Orley J. Mayfield (to Dr. Salsbury's Laboratories). U. S. 2,173,440, Sept. 19. A vaccine is prepd. from cultures taken from affected parts of poultry or birds afflicted with range paralysis or leucemia and sterilized after a period of growth sufficient to establish the property of immunizing individuals from these diseases.

Product having antiseptic, insecticidal, pest-destroying and medicinal properties. Thomas L. Shepherd. Brit. 508,407, June 30, 1939. The product is obtained by heating a mixt. of thymol 3 and salol 1 parts to the m. p. and cooling the mass so that crystals are formed. The product may be dissolved in various org. solvents or in terpineol or ti-tree oil, or may be dissolved in H_2O in presence of a sol. salt of cinnamic acid as described in Brit. 491,567 (*C. A.* **33**, 9943), or dissolved in H_2O by means of soaps and sulfonated fatty substances. An aq. prepn. may consist of the crystals, terpineol, Turkey-red oil and H_2O. The molten compn. or a soln. of the crystals may be finely atomized to sterilize the atm., and solns. may be used as general disinfectants, or for impregnating bandages, towels and handkerchiefs. The product may also be used as an internal disinfectant, as a curative to be applied to wounds or as an ingredient of gargles, toothpastes, etc. Solns. in paraffin, terpineol or ti-tree oil may be sprayed for destroying insects, used to impregnate insect-infested fabrics, etc.

Cosmetic creams. Benjamin R. Harris. U. S. 2,173,203, Sept. 19. A cosmetic of the vanishing-cream type comprises a plastic emulsion of oleaginous and aq. material and includes a compd., such as monostearate of diethylene glycol, having oleophilic and hydrophilic groups, the oleophilic group contg. at least 6 C atoms and the compd. having good wetting and lubricating properties, being miscible with water and capable of penetrating through the natural greasy layer on the skin and facilitating the softening of the hair when applied to the skin.

Tooth paste. Thomas I. Taylor. U. S. 2,172,743, Sept. 12. Na perborate is used with a boric acid ester of glycerol or of a glycol (suitably also with talc, tri-Ca phosphate, etc.)

Nail enamel. Henry C. Fuller. U. S. 2,173,755, Sept. 19. An org. ester of cellulose such as cellulose acetate butyrate 10 parts is dissolved in a mixt. contg. ethylene dichloride 25 and diethylene dioxide 40 parts, etc.

18—ACIDS, ALKALIES, SALTS AND OTHER HEAVY CHEMICALS

E. M. SYMMES

Contact sulfuric acid manufacture. XIX. Effect of H_2O and CO_2 gas on the oxidation of SO_2 by the V_2O_5 catalyst. Mototarō Matui and Raisaku Kiyoura. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 274(1939); cf. *C. A.* **33**, 9556[9].—In expts. with a gas mixt. contg. SO_2 7, N_2 73.5 and O_2 19.5%, H_2O vapor increases the

rate of oxidation over V_2O_5 catalyst at 400–425°, but CO_2 has no definite influence on the reaction. G. Ayers

Calcination of lime. XII. Effect of the addition of alkali chlorides, alkali fluorides, alkaline earth chlorides, and alkaline earth fluorides on the crystal growth of calcium oxide. Tōkiti Noda. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 265(1939); cf. *C. A.* **33**, 9558[1].—When chlorides or fluorides of Li, Na, K, Ca, Sr, Ba and Mg, resp., were added in the vapor state to $CaCO_3$, or mixed with it during calcination at 1100° for 3 hrs., LiF most effectively increased the cryst. size of the CaO formed, while with $MgCl_2$, NaF, KF, CaF_2, LiCl and MgF_2 vapor, the av. crystal size was 7 μ or larger. **XIII. Rate of hydration of calcium oxide calcined in the presence of vapors of alkali chlorides, alkali fluorides and alkali earth chlorides.** *Ibid.* 265.—The rate of hydration of CaO depends approx. on the size of the crystals. **XIV. Effects of adding sodium salts to calcium carbonate before calcining on the rate of hydration and on the microstructure of lime.** *Ibid.* 266–7.—Salts increase the crystal size of CaO, during calcination of $CaCO_3$, in the order: Na_2SO_4, Na_2CO_3 < $NaNO_3$, NaI, NaOH < NaCl <NaF. The rate of hydration of the resulting lime depends on (1) cryst. size, (2) state of aggregation, (3) velocity of soln. of the salts present, (4) quantity of mixed salts, and other factors. George Ayers

The helium content of common salt (halite) and sylvite. Berta Karlik. *Mikrochemie* **27**, 216–30(1939).—A review. W. T. H.

Exfoliation of vermiculite by chemical means. R. C. Groves. *Nature* **144**, 554(1939).—Vermiculite is completely exfoliated by cold, 20-vol. H_2O_2. The mech. strength of the wet product is low; when dry, it is about the same as that of the heat-treated material. Partial and slower exfoliation was obtained with various other oxidizing and reducing agents, such as $KMnO_4$, $K_2Cr_2O_7$, H_2CrO_4, NaBrO, Cl from $KMnO_4$ + HCl, and aq. SO_2. G. M. Petty

Studies of carbon black. V. The effect of gas composition on the production and properties of carbon obtained by nonimpingement (lampblack) methods. L. M. Pidgeon. *Can. J. Research* **17**, B, 353–63(1939); cf. *C. A.* **31**, 5114[8].—Lampblack has been produced from C_2H_4, C_3H_8, CH_4 and various mixts. of these gases. C liberated from the flame of burning olefins is similar to C black in its ability to reinforce rubber, while C from paraffins resembles lampblack and does not reinforce rubber. The production of a reinforcing pigment by nonimpingement methods is assocd. with a gas having a neg. heat of formation. J. W. Shipley

---

Manuf. of B-Mg fertilizers from mother liquors of H_3BO_4 manuf. (Berlin) **15.** Boiling pans [for concg. H_2SO_4] (Brit. pat. 508,993) **1.**

Phosphoric acid purification. Raymond J. Kepfer and Wm. R. Devor (to E. I. du Pont de Nemours & Co.). U. S. 2,174,158, Sept. 26. In the manuf. of secondary and tertiary Na orthophosphates by neutralization of crude H_3PO_4 with a Na base, a method of removing Pb and As impurities, whereby secondary and tertiary Na orthophosphates contg. less than 1 p. p. m. each of Pb and As can be obtained, comprises pptg. the Pb and As as sulfides by adding Na sulfide after at least 8% and before 63% neutralization, pptg. the Pb and As sulfides from the phosphate soln. before further neutralization and after a settling period of about 15–24 hrs., and thereafter further neutralizing to at least the di-Na phosphate stage and recovering solid Na phosphate.

Sulfuric acid. Carlten D. Koolman, Wolfhart Siecke and Max Wohlwill (to American Lurgi Corp.). U. S. 2,172,617, Sept. 12. An arrangement of app. is described, and a process for the manuf. of high-strength H_2SO_4, which comprises bringing into contact with a V oxide catalyst gases contg. SO_2, O and water vapor materially in excess of that required to react with the SO_3 equiv. to the SO_2 to form sulfuric acid monohydrate, withdrawing the gas mixt. comprising SO_3 and water vapor from contact with the catalyst while at a temp. above the dew point of the mixt., fractionally condensing liquid H_2SO_4 of a higher strength than corresponds to the amount of water present by cooling through the temp. range between the dew point of the mixt. and about 140°, while so obstructing the free flow of the gases as to maintain a high degree of turbulence in the gas mixt., which maintains substantial uniformity in temp. (excess water vapor remaining in the vapor phase in the uncondensed residue of the mixt.), and withdrawing the uncondensed residue from the condenser at a temp. between 140° and the b. p. of water.

Sulfuric acid. Earl S. Ridler and John F. W. Schulze (to E. I. du Pont de Nemours & Co.). U. S. 2,173,916, Sept. 26. For the catalytic production of SO_3, a mixt. contg. SO_2 and O is passed in contact with a Pt catalyst on a silica gel carrier and then in contact with a Pt catalyst on a $MgSO_4$ carrier.

Sulfuric acid. Société générale métallurgique de Hoboken. Brit. 508,055, June 26, 1939. Divided on 498,631 (*C. A.* **33**, 4748[1]). In the production of H_2SO_4 by the chamber or N oxide method with the use of 1 or several spaces or towers provided with filling material for the production of acid, followed by a Gay-Lussac space, which may also be provided with filling bodies, and with a space that is sprayed with a soln. of nitrosylsulfuric acid for the regeneration of N oxides, inserted between the production space(s) and the Gay-Lussac space, the 3 spaces (production, regeneration and absorption) are combined into 1 space or tower, the concn. of the acid for spraying this space or tower being maintained practically const. at 56–58° Bé. The filling materials may be irregular grains of an acid-resisting substance, e. g., quartzite. The middle or regeneration zone of the tower may be provided with a filling material having only a 4th of the surface of the filling bodies of the production zone. The lower part of the tower (production zone) and the upper part (absorption zone) may be provided with filling bodies having a surface as large as possible. The production zone should be sufficiently tall to ensure that the gases passing to the regeneration zone are cool.

Purifying sulfuric acid. Joseph P. Leemans and Société générale métallurgique de Hoboken. Brit. 508,302, June 26, 1939. Black or dark H_2SO_4 is bleached at about 260–300° by the action of SO_3 in the form of fuming H_2SO_4 or as a gas.

Sulfuric acid. Appareils & evaporateurs Kestner. Ger. 679,850, Aug. 16, 1939 (Cl. 12*i*. 25). Impure H_2SO_4, especially the waste acid used in petroleum refining, is purified by complete oxidation of the impurities by adding HNO_3 and sufficient concd. H_2SO_4 to bring the strength of the acid up to 75% of H_2SO_4, heating to about 200° and distg. off the impurities. The HNO_3 may be added as oxides of N. App. layout is indicated.

Diaphragms, particularly for use in the production of persulfuric acid or persulfates. E. I. du Pont de Nemours & Co. Brit. 508,045, June 26, 1939. These consist of a fabric woven from threads comprising a plurality of glass fibers. They may be formed as a cylinder enclosing the anode and surrounded by a helical tubular cathode, through which a cooling liquid is passed.

Sulfur dioxide recovery from gas mixtures, such as those from ore roasting. Arthur M. Clark, William E. Batten and Charles F. R. Harrison (to Imperial Chemical Industries Ltd.). U. S. 2,173,877, Sept. 26. An arrangement of app. is described, and a regenerative absorption process for the recovery of SO_2, which comprises absorbing SO_2 in an aq. soln. of basic Al sulfate in which the SO_3 to Al_2O_3 ratio is such that the SO_3 is insufficient to form the normal sulfate, but sufficient at least to keep substantially all the Al_2O_3 in soln., whereby substantially all the absorbed SO_2 may be regenerated without substantial pptn. of basic Al sulfate, and regenerating SO_2 therefrom.

Alkali chromates. Walter Hene. Brit. 507,362, June 14, 1939. In the production of alkali chromates, 100 parts of pulverized chrome ore is mixed with 10–20 of a powd. loosening material, e. g., CaO, MgO or residues

from a previous operation, and with not more than 75 of NaOH, or an equiv. quantity of other caustic alkali, and the mixt. is heated to 550–750° under oxidizing conditions. The caustic alkali may be mixed with the other materials in the form of a hot, concd. lye. 1

Peroxides. I. G. Farbenindustrie A.-G. Brit. 508,081, June 23, 1939. In a cyclic process for the production of peroxides, e. g., of alkali metals or H, by subjecting org. compds. that are oxidizable by O_2 under ordinary conditions in a liquid medium to such oxidation, with the formation of peroxides, sepg. the bulk of the peroxides formed from the reaction liquid and catalytically reducing the org. oxidation products to the initial org. compds., an essential part of the remainder of the peroxide and O dissolved in the reaction liquid is removed prior to the reduction. This may be effected by treating the reaction liquid prior to the reduction with oxidizable substances, e. g., $FeSO_4$, $MnSO_4$, an alk. suspension of $Fe(OH)_2$ or with substances that bind peroxides, e. g., NaOH, $NaBO_2$, Na_2CO_3, or with a catalyst that decomposes peroxides, e. g., Fe, Ni, Cu, Ag, Pt, Pd, PbO. The decompn. may be effected in conjunction with the removal of dissolved O by conducting the treatment with the decompg. catalyst in the presence of the reduced operating substance, which may be provided by not completing the preceding oxidation step or by branching off a portion of the reduced reaction liquid from the main cycle. The latter method of operation may be modified by treating the liquid with the decompg. catalyst in the absence of reduced operating substance, but in the presence of H and a reducing catalyst, e. g., Pd, Ni. The reducing catalyst may also serve as a decompg. catalyst. Dissolved O may also be removed by reducing the O pressure over the reaction liquid, e. g., by contact with an indifferent gas, e. g., H, or by reducing the pressure. The resulting mixt. contg. solvent vapor and O may be treated with a soln. of the reduced operating substance, which, by the absorption of O, restores the indifferent gas for further use in the process. The gas mixt. contg. expelled O may also be sucked off by means of a jet pump operated by the soln. of reduced operating substance. A plurality of the above methods may be used. An example gives a soln. of 2-ethylanthraquinone in a mixt. of C_6H_6 and methylcyclohexanol as the operating substance. 2 3 4 5

Aluminum-fluorine compounds. Rutgerswerke A.-G. (Veit Schwemmer, inventor). Ger. 679,849, Aug. 15, 1939 (Cl. 12*i*. 10). See Fr. 828,223 (*C. A.* **33**, 329[4]). 6

Ammonium nitrate. Wm. B. Gideon and Thorvald W. Hauff (to E. I. du Pont de Nemours & Co.). U. S. 2,174,238, Sept. 26. A process of producing substantially dry NH_4NO_3 of low d. and a puffed porous texture involves introducing into a closed chamber a hot melt of NH_4NO_3 of sufficiently low water content to be solid at ordinary temps., spreading the melt into a film over a heated surface within the chamber and subjecting the molten material to a pressure sufficiently below atm. pressure to remove substantially all of the water from the material and solidify it. App. is described. 7

Ammonium sulfate. Thomas B. Smith and Dorman, Long & Co. Ltd. Brit. 507,351, June 14, 1939. In the production of $(NH_4)_2SO_4$ by passing NH_3-contg. gases or vapors through a satd. soln. of $(NH_4)_2SO_4$ contg. free H_2SO_4, where the fall of the crystals is retarded by the maintenance of upwardly directed currents in the body of the soln., the currents are produced by injecting into the lower part of the saturator 1 or more streams of a satd. soln. of $(NH_4)_2SO_4$ from a point exterior to the saturator, with maintenance during the injection of an equiv. outflow of soln. from the upper layers of the body thereof in the saturator. App. is described. 8

Barium hydroxide. Albert T. Mertes (to E. I. du Pont de Nemours & Co.). U. S. 2,173,912, Sept. 26. For producing Zn-free, relatively pure $Ba(OH)_2$, a soln. of Ba sulfide is treated with a substantially equimol. proportion of ZnO or $Zn(OH)_2$ at temps. of about 103–200° under about 5–250 lb. superatm. pressure. 9

Beryllium fluoride free from oxide. Carlo Adamoli (to Perosa Corp.). U. S. 2,173,290, Sept. 19. See Can. 383,438 (*C. A.* **33**, 8367[2]).

Multiple-hearth furnace suitable for production of calcium metaphosphate from phosphate rock and phosphate reduction furnace gas. Harry A. Curtis and Roy C. Heaton. U. S. 2,173,825, Sept. 26. Various structural and operative details.

Cupric oxychloride. I. G. Farbenindustrie A.-G. Brit. 507,919, June 22, 1939. See U. S. 2,162,091 (*C. A.* **33**, 7503[2]).

Preparing normal ferric sulfate. Wm. S. Wilson and John F. White (to Monsanto Chemical Co.). U. S. 2,173,144, Sept. 19. Fe_2O_3 is treated with a substantially theoretical proportion of H_2SO_4 of sufficient concn. to form directly a dry ferric sulfate product, by mixing and grinding the ingredients under conditions whereby the temp. of the mixt. increases, and the reaction is completed with the materials in a quiescent state and under conditions whereby a temp. not substantially less than 140° is attained, so that a solid, substantially dry product is obtained, which is substantially completely caused to react to normal ferric sulfate, and the product is then ground or pulverized and subsequently agglomerated by the addition of water to form pellets of hydrated ferric sulfate, and the pellets are finally calcined to drive off the water. Cf. *C. A.* **33**, 8367[7].

Magnesium and calcium carbonates. Geo. Becze. Brit. 507,091, June 9, 1939. A loose cryst. product consisting of $CaCO_3$ and $MgCO_3$ is made by burning dolomite or other raw material contg. $CaCO_3$ and $MgCO_3$, forming an aq. suspension of the burnt material having an oxide content of not more than 8%, treating it with CO_2 or gases contg. CO_2 at at least 75° and preferably at 90° until neutral to phenolphthalein, sepg. the solid from the advantageously cooled suspension and drying and powdering it. In a modification, the neutral suspension is dild. to a MgO content of about 1%, CO_2 is again introduced until about a fourth of the $MgCO_3$ has dissolved, the suspension is heated and the carbonates that sep. are dried and powd. In a further modification, the neutral suspension is cooled, dild. with H_2O to about 3 times its vol., treated with CO_2 until the $MgCO_3$ has dissolved and basic Mg carbonate is pptd. from the sepd. soln. by boiling. The pptn. is preferably effected after the addn. of solid basic Mg carbonate or $Mg(OH)_2$. The products of the above 3 processes are suitable for heat-insulating purposes. The residue obtained on sepn. of the $Mg(HCO_3)_2$ soln. may be suspended in H_2O and treated with CO_2 to remove any residual $MgCO_3$, whereby a pure $CaCO_3$ is obtained.

Recovery of zinc values from galvanizers' skimmings. Robert J. Campbell (to E. I. du Pont de Nemours & Co.). U. S. 2,173,876, Sept. 26. A process for the recovery of Zn values from galvanizers' skimmings contg. NH_4Cl, $ZnCl_2$, basic Zn chloride and metallic Zn involves ball milling the skimmings with water to make a slurry contg sol. and suspendable matter, treating with lime to ppt. basic Zn chloride, filtering at a temp. not substantially higher than about 52° and with a concn. such that the filtrate has a d. not substantially greater than 5° Bé., reslurrying the filter cake obtained, treating the slurry with an excess of lime to convert Zn to $Zn(OH)_2$, sepg. the $Zn(OH)_2$ and dissolving it in H_2SO_4 to produce $ZnSO_4$.

Hydrogen peroxide. Antoine C. Semidei. Brit. 507,121, June 9, 1939. See Fr. 833,228 (*C. A.* **33**, 3087[2]).

Separating columbium from tantalum. François Cuvelliez and Société générale métallurgique de Hoboken. Brit. 507,124, June 9, 1939. Materials contg. Cb and Ta in oxide form are treated in a current of Cl or Cl-contg. gases, but in the absence of reducing gases, at approx. 1050° to volatilize the Cb as chloride or oxychloride, the Ta oxide being unaffected. Prior to the chlorination, the material may be mixed with a base, which is preferably CaO but may be BaO, NaOH or KOH. The base may be added as a carbonate and the mixt. heated to 800–1200° before the chlorination, with or without admission of air or in an inert or reducing atm., to cause the base to combine with the tantalic acid. The reducing atm., if used, should be free from carbonaceous gases.

Silicon from fluosilicate compounds. Josef Eringer. U. S. 2,172,969, Sept. 12. A compd., such as Na_2SiF_6, is

mixed with at least one finely divided metal more electropos. than Si, such as Na, and the mixt. heated to 500–1000° in a N atm., the reaction product is treated with acid, such as dil. H_2SO_4, to decompose the produced metal fluoride, and the Si is sepd. as an amorphous powder contg. about 96–97% Si and obtained in approx. 87% of the theoretical yield.

Hydrogen. James H. Shapleigh (to Hercules Powder Co.). U. S. 2,173,984, Sept. 26. App. is described and a process for prepg. H which involves passing reactants comprising gaseous hydrocarbons and steam downwardly through elongate vertical tubes contained in a heating zone, simultaneously heating the reactants indirectly by introducing hot flaming gases into the heating zone at a plurality of vertically spaced points along and adjacent to and substantially tangentially to the tubes, and withdrawing the resulting combustion gases at a point adjacent the top of the zone, whereby the flaming gases follow an upwardly ascending rotary path around the tubes, which are thereby uniformly heated without substantial flame impingement thereon. A catalyst of Ni on diaspore may be used.

Carbon black. Daniel Gardner. Brit. 507,516, June 16, 1939. C black is obtained from gases contg. C but no O, which may consist of satd. hydrocarbons and which may include vaporized hydrocarbons that are solid or liquid at normal temps. or natural gas from which any CO_2 has been removed, by mixing such gases with about 20% of N or CS_2 and heating to 1000–1200°. The furnace and cooling chambers may be made of graphite or carborundum.

Carbon black and carbon monoxide-hydrogen gas mixtures from natural gas, etc. Forrest C. Reed. U. S. 2,173,695, Sept. 19. An arrangement of app. is described, and a process which comprises alternating the periods of combustion and dissociation of hydrocarbons within closed retorts, sepg. CO_2 from the gases of combustion, subjecting hydrocarbons to dissociating temps. during said dissociating periods for producing a gas mixt. of CH_4 and H, utilizing said CO_2 to cool the products of dissociation by heat exchange therewith, catalyzing any unsatd. compds. present to CH_4, then adding said CO_2 to said CH_4 and H and subjecting the resultant mixt. to high temps. to produce said CO_2-H gas mixts.

Catalysts. Walter H. Groombridge and John E. Newns. Brit. 507,419, June 9, 1939. Metallic compns., particularly for use as catalysts, e. g., in the hydrogenation of C compds., especially CO, are obtained by heating a mixt., preferably finely divided, of a heavy metal oxide with another metal of higher affinity for O, so as to obtain a porous structure of 1 heavy metal oxide permeated with and acting as a support for an oxide of the other heavy metal, which is then reduced with a gaseous reducing agent to form a porous nonfriable structure of the heavy metal of lower affinity for O, permeated with the metal of higher affinity for O. Examples describe the prepn. of catalysts by heating CuO with Ni or Co at 900°; the products are broken to about 0.25-in. mesh and reduced by water gas at 350°; the catalysts may be used for the *conversion of CO and H to CH_4*. Other substances may be applied to or incorporated in the metallic compns., e. g., ThO_2 may be applied or incorporated to give a catalyst suitable for synthesizing hydrocarbons from CO and H. The catalysts are also suitable for other reactions, e. g., the conversion of EtOH to Me_2CO, or reactions in which the metals combine with and remove O and halogens from compds. In Brit. 507,420, June 9, 1939, a metallic compn. comprising Fe and Cu is obtained by heating a mixt. of finely divided Fe and CuO to above 600° to form a hard, sintered mass comprising Cu_2O permeated with Fe oxide, which is, after being broken into granules, reduced, e. g., with water gas or producer gas at 500–800°. The product is used particularly for the manuf. of H from steam, as in the Lane process, or from liquid H_2O under pressure, as in the Bergius process.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

More recent researches on the history of the glass industry in the Sudeten District. H. Kühnert. *Gla tech. Ber.* **17**, 271–5(1939). J. F. Hyde

Beneficiation of some Alabama glass sands. R. F. Havell and T. N. McVay. *Bull. Am. Ceram. Soc.* **18**, 129–31(1939).—Tests showed that by tabling, the Fe content could be reduced from a range 0.093–0.169 to 0.057–0.066% Fe_2O_3. Small amts. of zircon, kyanite, ilmenite and rutile may be recovered as by-products. C. H. K.

The state of aggregation of glass. R. E. Liesegang. *Glastech. Ber.* **17**, 269–71(1939).—Various prevalent conceptions of the state of aggregation are briefly discussed. Simplification would seem to result if glass were considered to be a mixt. of particles varying in size from coarse down to mol. dimensions. The mol. sizes in the viscous condition impart to the coarser aggregates a certain mobility, thus acting as a lubricant. A detn. of the aggregate size distribution would be of more importance than defining the state of aggregation. It is no mistake to call glass "solid," if the expression "solid state of aggregation" is avoided. In any case the idea prevails at present that classification of materials as solid, liquid or gas is too superficial. J. F. Hyde

High-temperature viscosities of soda-silica glasses. H. R. Lillie. *J. Am. Ceram. Soc.* **22**, 367–74(1939).—A study of glasses composed of SiO_2 and 22–40% Na_2O showed that viscosity-compn. isotherms were smooth curves. The sharp minima at about 34% Na_2O (and possibly at about 26% Na_2O) observed by Preston (cf. *C. A.* **32**, 7229[2]) were absent. Neither time nor shearing stress had any effect upon observed viscosities in the region investigated so long as temp. constancy had been established. Deviations of individual points from the smooth isotherms were all within the limits of exptl. error. C. H. Kerr

Vanadium as a glass colorant. W. A. Weyl, A. G. Pincus and A. E. Badger. *J. Am. Ceram. Soc.* **22**, 374–7(1939).—In a wide range of types of glass, V, as a glass colorant, acts much like Cr. Ordinarily it leads to green tints owing to the superposition of the green of trivalent V and the yellow of quinquevalent V. Large excess of alkali leads to the formation of colorless vanadates. Under special conditions solarization will develop the lavender color of bivalent V. Melting conditions may have considerable influence upon the color. C. H. Kerr

Effect of firing schedule on quality of glass color decorations. Campbell Robertson and Daniel O. Koch. *Bull. Am. Ceram. Soc.* **18**, 422–6(1939).—A study was made of the effect of the firing schedule on the quality of vitrifiable glass color decorations applied by the screen process. An exptl. gas-fired decorating lehr with a 30-ft. tunnel was used. The firing schedule was varied widely. The medium was effectively removed in the shortest time at about 1075°F. Different media showed considerable variation in firing behavior, and this seems to offer a means for control of results. As a factor in firing, the effect of the medium is at least as important as the firing cycle itself. Thickness of color application is also a factor. C. H. Kerr

Effect of alumina on devitrification of soda-lime-silica glasses. W. B. Silverman. *J. Am. Ceram. Soc.* **22**, 378–84(1939).—The effect of the substitution of Al_2O_3 for the oxides of Na, Ca and Si on the liquidus temps. and phase relations was detd. for glasses lying within the compn. range Na_2O 11–19, CaO 6–18, SiO_2 59–79, and Al_2O_3 0–8%. The results of 137 individual detns. show that the substitution of Al_2O_3 for CaO permits wollastonite to be the primary phase in glasses of relatively low CaO content. As the Al_2O_3 increases the $Na_2O.3CaO.6SiO_2$–$CaO.SiO_2$ boundary shifts to lower CaO contents and the decompn. of $Na_2O.3CaO.6SiO_2$ to $CaO.SiO_2$ takes place at lower temps. In compns. with tridymite as a primary

Cutting and firing sized ceramic particles from materials such as plastic clay. Earnest T. Hermann. U. S. 2,172,638, Sept. 12. Various details of app. and operation.

Press suitable for molding ceramic materials. Stuart M. Phelps (to Ceramic Products Co.). U. S. 2,173,593, Sept. 19. Various structural and operative details.

Ceramic flatware articles. Robert E. Gould. U. S. 2,173,107, Sept. 19. A process of making a plurality of ceramic flatware articles such as china or porcelain articles which have substantially identical dimensions involves superposing for subsequent firing a plurality of ceramic elements comprising a plurality of leather hard ceramic articles, preformed from plastic material, a leather hard ceramic sepg. element, preformed from a plastic material which has substantially the same physical properties as the plastic material from which the ceramic articles are formed, supporting each ceramic article in the zone of greatest potential deformation during firing, a leather hard setter being used, preformed from a plastic material of like physical properties with at least a part of the obverse of the setter substantially identical to the obverse of the leather hard ceramic articles, and a fired refractory setter the obverse of which is complementary to the reverse of the leather hard setter. Cf. *C. A.* **33**, 3098[9].

Fusing and working quartz. Franz Skaupy and Gustav J. Weissenberg. Brit. 508,013, June 20, 1939. Articles of vitreous sintered quartz are produced in a process wherein the quartz is so heated that it does not remain longer than 15 min. within the region of crystobalite formation, particularly within the range 1470–1710°. The temp. may be raised for a short time above 1710° immediately after the sintering operation to increase the d. of the surface of the article. Small amts. of alkali may be added to the quartz to reduce the sintering temp. The powd quartz may be mixed with a plasticizer, e. g., cellulose dissolved in AcOAm, and a proportion of the powder may consist of coarser grains to prevent shrinkage. Colored articles may be made by mixing suitable metal compds. with the quartz. Shaped parts of metal or of refractory oxides may be inserted in the molded quartz and if W, Mo or Ta inserts are used they may be given a coating of metal of the Pt group before insertion to make a vacuum-tight joint. A *spinneret for making rayon* may be made by embedding Pt pins in the shaped quartz and drilling them out after the sintering. Cf. *C. A.* **33**, 1901[9].

Textile threads from quartz. W. C. Heraeus G. m. b. H. Brit. 507,951, June 23, 1939. A continuous fine thread of quartz is made by feeding a coarse thread into a hot gaseous stream in the direction of flow of the gas, whereby the coarse thread is softened and drawn into a continuous thread of microscopic fineness. The fine threads may be made into yarns, felt or fabrics or may be used for filtering, elec. or thermal insulation or sound damping.

Blunging crude kaolin. Sanford C. Lyons (to Bird Machine Co.). U. S. 2,173,975, Sept. 26. App. is described, and a method of blunging crude kaolin of intrinsically fine particle size and contg. oversized impurities of the nature of sand and mica, which comprises streaming such kaolin in the form of an aq. suspension contg. a substantial fraction of palpable aggregates of the ultimate kaolin particles in between and out of the sphere of action of relatively moving resilient surfaces clearing each other by such small definite gap and at such high relative speed as is attended by shearing and rubbing action on the aggregates and liberation in the aq. suspending medium of the ultimate intrinsically fine particles while the oversized impurities are preserved in essentially unreduced size.

Surface-colored chinaware. Edward Schramm (to Onondaga Pottery Co.). U. S. 2,174,198, Sept. 26. A method of producing surface-colored American vitreous chinaware involves shaping the ware from body material in a moist condition and of such compn. as to be fused and sintered by a biscuit-firing operation into a hard vitreous body characteristic of American vitreous chinaware, drying the shaped ware and thereafter coating the ware surface to be colored with an engobe comprising a pigmented material, biscuit firing the coated ware, the pigmented material being of such compn. that it is fused and sintered by the biscuit-firing operation into a colored surface portion of the ware in permanent adherence, and similar in hardness and in its vitreous character, to the fused and sintered body, applying a decorative design to the engobe-treated surface of the biscuit-fired ware, then coating the ware with glaze-forming material and then glaze firing the ware at a temp. below the biscuit-firing temp.

Asbestos tiles. Gertrude Schless (nee Winkler). Ger. 679,968, Aug. 17, 1939 (Cl. 80*b*. 17.05). Both sides of asbestos tiles are coated with a glossy covering contg. inorg. material such as a mixt. of $CaCO_3$ and nitrocellulose.

Ceramic insulator. Steatit-Magnesia A.-G. (Ernst Albers-Schonberg, inventor). Ger. 679,917, Aug. 18, 1939 (Cl. 80*b*. 8.08). An insulator for installing elec. steam boilers consists of MgO 5–18, Al_2O_3 30–50 and SiO_2 40–65%. An addn. of 2–6% Fe_2O_3 may be given.

Balanced draft and flash wall for kilns such as those used for burning ceramic products. Lawrence R. Robinson (to United Combustion Corp.). U. S. 2,173,614, Sept. 19. Various structural details.

Refractory mass. Didier-Werke A.-G. Ger. 679,915, Aug. 16, 1939 (Cl. 80*b*. 8.01). Magnesite or substances contg. MgO, and Cr ore are finely ground and intimately mixed. Part of the mixt is molded, fired and granulated. The rest is added to this and the whole molded and fired, to form refractory stone.

Abrasive coated paper. Nicholas E. Oglesby (to Behr-Manning Corp.). U. S. 2,173,796, Sept. 19. Abrasive grits are attached, by a water-sol. adhesive, such as an animal glue, to a paper backing sheet contg., as a softening agent, triethanolamine oleate or sorbitol.

Abrasive articles such as grinding wheels. Wm. P. Fitz-Randolph (to The Carborundum Co.). U. S. 2,173,833, Sept. 26. Diamonds are used with a sintered metal bond consisting principally of Sn with an alloying agent such as Cu or Sb which hardens the Sn. U. S. 2,173,834 relates to the use of an abrasive comprising diamonds and a bond comprising a sintered mixt. of Sn and Fe powders contg. not more than about 30% Fe. U. S. 2,173,835 (Wm. P. Fitz-Randolph and John A. Boyer, joint inventors; to same assignee) relates to the use of abrasive particles such as diamonds with a sintered bond consisting principally of an alpha solid soln. in which the metal forming the basic lattice structure is a metal of the Fe group and the metal retained in solid soln. is Al, Zn or Sn (suitably in a quantity up to about 33% that of the Fe group metal).

Grinding wheels. Herbert W. Wagner and Kenneth F. Whitcomb (to Norton Co.). U. S. 2,173,461–2, Sept. 19. Various structural and mfg. details of grinding wheels formed of abrasive material and a binder.

Grinding wheels. Deutsche Norton-G. m. b. H. (Lowell Haines and Robert Hamilton, inventors). Ger. 679,918, Aug. 18, 1939 (Cl. 80*b*. 11). App. for molding grinders from matrix and diamond powder is described.

Grindstones. Horbach & Schmitz. Ger. 679,919, Aug. 16, 1939 (Cl. 80*b*. 11). Grinders are made from quartz and granulated or powd. pumice, with a MgO cement as the binding agent.

Glazes. Dietrich Harkott. Ger. 679,866, Aug. 17, 1939 (Cl. 80*b*. 23.03). A ceramic glaze or enamel contains a substance which is oxidizable above 650°, such as metal carbide or powd. Al. Thus the glaze may consist of 2–3% of SiC and varying amts. of chalk, fluorspar, B_2O_3, galena, sand, etc.

Glasses, glazes and enamels. Auergesellschaft A.-G. Brit. 507,823, June 21, 1939. The compn. of silicate melts e. g., glasses, etc., that are opacified by ZrO_2 and are subjected to prolonged heat-treatment during manuf. is so selected that the ZrO_2 is not absorbed, or does not form double compds. with other constituents of the melt, under the prolonged heating. In particular, with aluminous silicate melts the proportions of SiO_2 and Al_2O_3 should not exceed 7:1. The ZrO_2 can be produced during fusion from double compds. that yield the ZrO_2 under heat, e. g., NaZr silicate or Pb zirconate.

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Mineralizers in cement—results of recent investigations on the use of mineralizers in the manufacture of portland cement. E. P. Flint. *Rock Products* 42, No. 10, 40–2, 52 (1939).—A continuation of the Bates and Klein and the Flint and Wells studies of the effect of small proportions of fluxes (CaF_2, $BaCO_3$, etc.) on the compn. and calcining temps. of portland cement clinker. The fluxes used in the present studies, which are being continued for long-time strength data, are $CaCO_3$, granular silica gel, Fe_2O_3, Al_2O_3, $MgSiF_6.6H_2O$, CaF_2, Ca phosphate, B_2O_3 and Na_3AlF_6. Results obtained with CaF_2 fit the theory proposed by Eitel (*C. A.* 32, 9429[3]); the advantages of $MgSiF_6$ as a flux useful in the manuf. of portland cement clinker are discussed in detail. This study shows that the calcination of sulfate-resistant portland cements in which the Al_2O_3 and Fe_2O_3 were reduced to 3% can be facilitated by the addn. of so-called mineralizers (catalysts, fluxes) already mentioned. A. W. King

The effect of the addition of finely ground inert material to concrete. Robert Chapman and Paul E. Olsen. *J. Inst. Engrs. Australia* 11, 263–78(1939). G. Ayers

Possible relationship between tarring of highways and the increase of incidence of pulmonary primary cancer. André Kling, N. Samssonov and Marguerite Heros. *Bull. acad. méd.* 121, 784–91(1939); cf. *C. A.* 33, 8779[6].—Since tar contains benzopyrene, a recognized cancerigenic agent, it cannot be considered as inoffensive. Expts. on mice definitely confirm this assumption. A. E. Meyer

The preservation of wooden telegraph poles in the German postal service. K. Winnig. *Holz Roh- u. Werkstoff* 2, 272–8(1939).—The experience of the German postal service with standard processes and materials for preserving wood are briefly summarized. $ZnCl_2$ and $CuSO_4$ are about equally effective; $HgCl_2$ is slightly superior. A complete impregnation with coal-tar creosote is more economical than these salts because of a nearly double service life. Tanalith is the most effective of the modern preservatives used. Some data on internal pressure prevailing in the Boucherie process are given. R. H. B.

A new method of impregnating green fence posts. A preliminary report. W. C. Nettles. *J. Econ. Entomol.* 32, 703–1(1939).—The following method was used to treat nondurable green pine posts with sol. preservatives in order that they would resist insects and decaying organisms. Six-foot posts are immersed, immediately after cutting, top end down in a trough for 3 hrs. A 1-in. disk is sawed off the basal ends of the posts to remove resinous material. The basal ends are then placed in a soln. of $CuSO_4$, 2 lb. per gal. As soon as the soln. is absorbed (24–48 hrs.) remove the posts from the trough and reverse ends. Let the posts stand up for 2–4 weeks and preferably till thoroughly seasoned. About 0.75 lb. of soln. is required for each cu. ft. of wood. The investigation is being continued. Charles H. Richardson

---

Economic geology of Panchet Hill [building stones and road materials] (Roy) 8.

Hydraulic cement mixtures. Kaspar Winkler. U. S. 2,174,051, Sept. 26. A process of treating mortar-like binding agents to reduce the water-cement factor thereof consists in increasing the fluidity of the suspensoids thereof by treating the binding agents with up to approx. 2%, based on the wt. of the hydraulic cement, of a nonfoaming org. carboxylic acid compd. contg. at least two hydroxy groups combined by aliphatic groups in the nucleus, such as saccharic acid.

Cooling cement clinker. Einar Ronne (to F. L. Smidth & Co.). U. S. 2,173,182, Sept. 19. App. is described, and a method of cooling cement clinker produced in a rotary kiln which involves adding cooled clinker to that in the kiln at a point beyond the clinkering zone.

Floorings of cement, etc. William C. Treuhaft (to Tremco Mfg. Co.). U. S. 2,172,628, Sept. 12. A method of prepg. a composite floor structure comprises applying a mortar composed essentially of an aggregate, hydraulic cement and an emulsified bituminous material to a suitable surface to form a foundation layer, leveling the layer and permitting it partially to dry until it is capable of sustaining the wt. of an ordinary individual without forming appreciable foot marks, applying a thin upper layer composed essentially of a hard, wear-resisting aggregate, a pigment and hydraulic cement in an amt. sufficient to bind the aggregate and pigment together when set, and compressing the upper layer upon the foundation layer to force upper-layer particles into the pores of the lower layer and to cause the hydraulic cement to draw sufficient moisture from the lower layer to bind the pigment and aggregate together and to cement the upper layer to the lower layer. U. S. 2,172,629 relates to a method of prepg. a flooring having a terrazzo effect, which comprises mixing a minor portion of a hydraulic cement with a major portion of ornamental chips to form a uniform mortar of av. consistency, mixing emulsified asphalt with the mortar in an amt. substantially in excess of the hydraulic cement, applying the compn. to a foundation, levelling the compn., allowing the compn. to stand until it can be floated and then floating the compn. to bring a portion of the ornamental chips to the surface.

Sintering or calcining raw materials such as those for cement production. Nikolai Ahlmann (to F. L. Smidth & Co.). U. S. 2,174,066, Sept. 26. App. is described, and a process for sintering or calcining raw material which comprises forming a layer of porous fine-grained heat-recuperative material on a traveling gas-pervious support, forming on top of the first-named layer a porous fine-grained layer of the material to be sintered or calcined, passing a heated gas transversely through the layers as at least a part of the sintering or calcining operation, thereafter passing downwardly through the layers an unheated gas which transfers the heat contained in the top layer of the material to the underlying heat-recuperative layer, then removing the top layer of material from the underlying layer, thereafter passing a cooling gas through the recuperative layer from which the top layer has been removed to absorb in the gas the heat in the recuperative layer, and utilizing the last-mentioned gas as the first-mentioned heated gas which is used as part of the sintering or calcining operation.

Concrete. Hermann Leitz, Carl Unverzagt and Paul Betzler. Ger. 679,914, Aug. 15, 1939 (Cl. 80*b*. 4.08). A cement made from granular MgO or Mg salts and granular flux material is used as concrete for fixing Fe and steel girders in buildings. $MgCl_2$ and ground $CaCO_3$ or dolomite may be used.

Pavement expansion joint with an asphalt and copper seal. Robert R. Robertson (to Translode Joint Co.). U. S. 2,172,773, Sept. 12. Various structural details.

Expansion joints; rubber compositions. International Latex Processes Ltd. Brit. 507,731, June 20, 1939. An expansion joint is formed in a space between 2 constructional members, e. g., paving slabs, by insertion of a compressible and expansible material in the space and anchoring it to the members by the formation *in situ* between the material and the members of a deposit of solids from an uncoagulated "latex" compn., the term "latex" signifying a coagulable aq. dispersion of elastic materials, including artificial dispersions of rubber as well as natural rubber. Suitable latex compns. are (1) centrifuged latex, KOH soln., S paste, diamylammonium diamyldithiocarbamate (I) emulsion, Na silicate, whiting and ZnO paste, (2) rubber reclaimed from tires, whiting, rosin, ZnO, S, NaO and tetramethylthiuram monosulfide (II). The I and II act as low-temp. accelerators. A further compn. comprises the ingredients of I with the addn. of casein soln., a china clay aq. dispersion and aluminous cement, to which may be added a 33⅓% dispersion of Na_2SiF_6 as a delayed coagulant before pouring into the joint. The Na_2SiF_6

dispersion may be replaced by an aq. emulsion of pine tar or a polyvalent metal salt. The latex compd. may be made heat-sensitive by the addn. of polyvalent metal salts, disubstituted guanidines or an NH_4 salt of a strong acid and ZnO. In the case of a heat-sensitive latex that is not coagulable at normal temps., the compd. may be heated *in situ*, e. g., by playing hot steam on the joint, to produce more or less immediate gelling. 1

Coating compositions. Granitese (Great Britain) Ltd., Grenville J. Staples and James C. B. McGuffie. Brit. 508,025, June 23, 1939. A cold-glazing prepn., for application to brick, stone, concrete, plaster, etc., comprises a mixt. of portland cement and an aq. emulsion of china-wood oil. A pigment may be added. The surface to be treated is preferably first set with a mixt. contg. sand, portland cement and a waterproofing agent and the glazing prepn. is then sprayed thereon. After hardening, the glaze may be coated with a waterproofing medium, e. g., an emulsion contg. H_2O, beeswax, K_2CO_3 and fish glue. 2

Artificial stone. Louis Czajko. Ger. 679,920, Aug. 16, 1939 (Cl. 80*b*. 17.05). A mixt. of disintegrated asbestos fiber, cement and other optional materials is moistened in a rotating drum and molded under pressure to form stone slabs.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER AND A. GEORGE STERN

Calculating water in combustion of gaseous fuels. J. F. Anthes. *Gas Age* **84**, No. 8, 67–8(1939).—A 10-cc. sample of gas mixed with a measured vol. of air is exploded or burned by slow combustion. The contraction is noted and the amt. of CO_2 and excess O are detd. A sample of the same gas is analyzed for CO_2, CO, O and illuminants. The cu. ft. of water vapor per cu. ft. of gas burned = 2{[(0.209 × cc. air used per 10 cc. gas burned − cc. excess O)/10 − 0.5 cu. ft. of CO per cu. ft. of gas + cu. ft. O per cu. ft. of gas] − [(cc. CO_2 produced per 10 cc. gas burned)/10 − cu. ft. of CO_2 per cu. ft. of gas − cu. ft. of CO per cu. ft. of gas]}. Joseph H. Wells

The vegetable oils as Diesel motor fuels. B. Ilieff. *Österr. Chem.-Ztg.* **42**, 353–6(1939). - The uses of sunflower oil, cotton oil and olive oil as Diesel motor fuels are discussed. Sunflower oil and cotton oil can be sprayed equally as well as gas oil. The olive oil could not be sprayed. The sprayed pure oils could not be ignited by an open flame but a small addn. of gas oil improves the ease of ignition. The action of the motor with sunflower oil and cotton oil is as stable as with gas oil. The fuel requirements are greater with the vegetable oils than with gas oil. In relation to the max. power, the vegetable oils and the gas oil are equiv. By continued use of sunflower oil, the atomizer becomes clogged but this can be overcome by the addn. of a few % of alc. Olive oil with 15% alc. can be readily sprayed and ignited but the fuel requirement is higher than with the other vegetable oils. Olive oil contg. 30% alc. causes stoppage of the atomizer. The best results are obtained by a mixt. of 36% olive oil, 60% cotton oil and 4% alc. The vegetable oils show a higher efficiency than gas oil. Joseph H. Wells 3 4 5 6

New points of view concerning the ignition process in the Diesel motor. Karl Zinner. *Z. Ver. deut. Ing.* **83**, 1973–9(1939).—A review, with 46 references. Five new photographs show (1) the rapid (3×10^{-5} sec.) dispersion of part of the injected fuel into very small drops, (2) the wide spread of the fuel spray during the ignition lag and (3) the decrease in rate of burning from the moment of ignition on. H. A. Beatty 7

Calorific power of woods. Gabriel Bertrand and Georges Brooks. *Compt. rend.* **209**, 733–6(1939).—See *C. A.* **33**, 6027[1]. C. A. Silberrad

The fundamental principles of segregation. R. L. Brown. *Glass* **16**, 422–6(1939).—General principles applied to *coal*. 22 references. Herbert S. Willson 8

A proposal for the evaluation of coal-cleaning processes. W. Riebeck. *Glückauf* **75**, 213–19(1939).—Lab. tests were made to det. the relation between sepg. d., distribution and grain size for various coal-cleaning processes and the results were plotted in a simple form. Information obtained from the graphs is used to indicate the most economical method for coal sepn. L. P. Rockenbach 9

Sulfur study of some Tertiary coals of Khasi Hills, Assam. N. N. Chatterjee. *Quart. J. Geol., Mining Met. Soc. India* **10**, 135–41(1938).—Proximate analyses of coals from Cherapunji, Laitringow and Thanginat are given with addnl. detailed data on S content. Big lumps of pyrites were picked out and eliminated, before the coals were analyzed. S retained by the coke is very high and these cokes are not suitable for metallurgical operations. J. F. Schairer

The effect of grinding and blending coal on the coke quality. Hans Siebel. *Gas- u. Wasserfach* **82**, 721–6, 736–41(1939).—The purpose of these tests was to det. the best size and proportion of the various available coals to be used for making the most suitable coke for central heating plants and ovens. The coals tested included nut and small Ruhr high-volatile coal, small, nut and single Durham coal, and Yorkshire smalls. The tests made on each coal included petrographic examn., caking test, crucible coking test and carbonization in the Jenkner retort, followed by qual. and quant. examn. of the coke structure and friability. The carbonization and coke-quality tests were repeated on a large no. of blends and the results of 23 tests are tabulated. As a result of the petrographic examn. and a study of the coke properties it was detd. that the Durham and Yorkshire coal (with one exception) should be ground to pass a 3-mm. sieve while one Durham small coal and the high-volatile Ruhr nut and fine coal should not be ground. Relative coke density was found to be satisfactorily estd. by an examn. of prepd. sections (d. was also detd. gravimetrically). It was found that suitable grinding and blending of the coals greatly improved the quality and permitted the utilization of poorly coking coals, even high-inert nut coal, to be carbonized to a satisfactory coke. Mills and accompanying plant are briefly discussed. R. W. Ryan

Synthetic plastics and the gas industry. Albin Marty. *J. usines gaz* **56**, 420–2(1939).—A brief review on coumarone-indene and styrene resins and their uses. B. J. C. van der Hoeven

Fuel gas. Tests of gas engines. A. Pignot. *Chaleur et ind.* **20**, 511–16(1939); cf. Larivière, *C. A.* **33**, 8958[8].—Difficulties in accurate detn. of engine combustion efficiency are discussed. H. A. Beatty

Enriching producer gas. I. M. Rafalovich. *Vestnik Inzhenerov i Tekh.* **1939**, No. 9, 388–91.—Various methods of removing CO_2, H_2S and SO_2 from producer gas by phys. and physicochem. means are briefly discussed. The Girdler method (cf. U. S. pat. 2,065,112, *C. A.* **31**, 841[8]) is considered the most satisfactory. B. Z. Kamich

Colored gas flames. J. E. Hovingh and J. de Vries. *Gas- u. Wasserfach* **82**, 703–4(1939).—Colored gas torches for street illumination were prepd. by placing in the flame a refractory first impregnated with the desired salt and then coated with the solid salt. However, the intensity of the color soon decreased owing to fusion of the salt; this was remedied by causing a fine stream of water to fall on the refractory. For longer periods, better results would be secured by introducing a steady slow stream of a soln. of the desired salt into the flame, using an all-glass system for handling the soln. so as to avoid contamination. R. W. Ryan

Experiences with dry (sulfur) purification of gas. II. Hermann Deneke. *Gas- u. Wasserfach* **82**, 687–9(1939).—In the previous article (*C. A.* **32**, 3127[6]) it was shown that the efficiency of gas purification was increased by rearranging the purifier boxes so that the gas velocity through each layer was increased by placing a no. of layers in series.

This study was continued on a practical basis, confirming earlier findings. The boxes were grouped in 2 series, pre-purification and after-purification. In the pre-purifier boxes it was possible to reach a S content of 55% before discarding the purifying material as against 48% in previous practice. In a new plant the boxes would be designed so that the after-purifiers could be placed in the pre-purification state after partial fouling. The change in gas velocity through the purifier boxes had no effect on final O concn. of the gas; this was high owing to leaks at retort doors. R. W. Ryan

Gas for syntheses from peat. A plant trial in the Tiefstack plant of the Hamburg gas works. Gustav Keppeler. *Chem. Fabrik* **1939**, 457–62; cf. *C. A.* **33**, 1911[8], 5630[9].—The Pintsch-Hillebrand process for producing water gas is discussed, and a vertical section through the producer, a flow-sheet and an elevation of the plant are shown. The app. was used on ordinary raw peat contg. 28–30% H_2O, which was charged just after using lignite briquets, the expts. beginning about 70 hrs. after starting to charge the peat, with temps. of 1200 and 1300°. Data are given on heat balance, peat consumption, gas yields and analyses, the latter averaging about 15, 27, 54, 2.5 and 1.8% CO_2, CO, H, CH_4 and N, resp. Estd. plant and production costs based on Pintsch data are given, and it is concluded that a synthetic gas plant is feasible in peat regions. Five references. J. H. Moore

The clinker problem in small gas producers. R. Rasch. *Glückauf* **75**, 239–42(1939).—A study of the clinker problem in small gas producers for motor vehicles has shown that the melting property of the ash in connection with the "fire-clay refractory" is dependent upon the CaO content. Ash low in CaO has little effect upon the refractory, but because of its high soly. effect forms clinkers. For this type of fuel, water-cooled producers are preferable. High CaO content retards the formation of clinker, so that for such fuels a producer lined with fire clay is best. L. P. Rockenbach

Determination of hydrogen sulfide and hydrocyanic acid in manufactured gas. Theo Payer and Adolf Lehrenkrauss. *Gas- u. Wasserfach* **82**, 713–15(1939).—When an attempt is made to apply the Tutweiler I titration method to the detn. of small amts. of H_2S in purified manufd. gas, erroneous results are obtained owing to HCN forming ICN. The method has been modified to give more accurate results and also to permit the detn. of HCN as well. When HCN is not to be detd. starch soln. is added to approx. 500 cc. of gas in the Tutweiler app. and the soln. titrated to faint permanent blue with 0.01 gas-normal I soln. (1 cc. of a gas-normal soln. = 1 cc. of gas constituent to be detd., under standard conditions). The Tutweiler app. is then washed out into a flask and 1 cc. of fresh 5% KI soln. added, after which the soln. is acidified with a little dil. HCl. The soln. is then titrated with 0.01 gas-normal $Na_2S_2O_3$ solution. This titration is subtracted from the first to give the value for H_2S, and when this difference is multiplied by 2.84 the product is g. of H_2S per 100 cu. m. For detn. of HCN, the method is modified by adding a known excess of I soln. to the Tutweiler app. after the faint blue color appears. Results for HCN by this method check well with those by the Feld method. R. W. R.

Supervision of [Diesel] exhaust gases. H. Kuhlman. *Glückauf* **75**, 350–1(1939).—The CO content of a Diesel exhaust can be rapidly detd. by means of a Drager type T-CO measuring app. This outfit employs a catalytic cartridge which rises in temp. as air contg. CO is passed through it. From a linear relationship between temp. and CO content the exact amt. of CO is detd. L. P. R.

Carbon monoxide content in Diesel exhaust. H. H. Müller-Neuglück. *Glückauf* **75**, 337–46(1939).—The formation of CO is affected by the ignition characteristics and chem. compn. of the oil, faults of injection or other mech. defects. A complete review of the methods of obtaining and analyzing samples of mine air and Diesel exhaust is given. A ventilating air supply of 6 cu. m. (215 cu. ft.) per h. p. per min. provides a large margin of safety above the toxic limit. L. P. Rockenbach

Condensation of moisture from boiler flue gases. A. C. Walshaw. *Eng. Boiler House Rev.* **53**, 307(1939).—Calcn. of the temp. at which moisture (and subsequent corrosion from acid solns. formed) will be deposited from flue gases involves (1) estn. of the partial pressure of water vapor in the gases, and (2) use of steam tables to find the corresponding satn. temp. George Ayers

Refining regenerator gas tar by thermal treatment. A. Jäppelt and A. Steinmann. *Glückauf* **75**, 596–601 (1939).—The tar obtained from the distn. of poor- or non-coking coals in regenerator-type coke ovens is not suited for use as fuel oil without some treatment such as hydrogenation or distn. Expts. with these tars have shown that by reheating up to about 370° there is a decrease in sp. gr. and viscosity. Above this temp. the sp. gr. and viscosity increase rapidly and the tar acid yield decreases. The effect of time of heating on the tar is also important. Seven sec. appears to be the optimum time of heating. Tar thus treated at a comparatively low cost has the same ignition pt., higher heating value and lower sp. gr. and viscosity than the original tar and does not change appreciably during long periods of storage. L. P. R.

Portable app. for analysis of mine gases, motor exhaust, etc. (Schmidt) **1**. Colorimetric detn. of CS_2 [in motor fuel] (Demann, Adelsberger) **7**. Isolation of 2,2-dimethylbutane from natural gas (Hicks-Bruun, *et al.*) **10**. Coal deposits of the Eastern Urals (Shekhunov) **8**. Amino glycols [for absorbing CO_2 and H_2S from industrial gases] (U. S. pat. 2,174,282) **10**. C black and CO-II gas mixts. from natural gas, etc. (U. S. pat. 2,173,695) **18**. Drilling gas wells (U. S. pat. 2,174,027) **22**.

Motor fuel. Lebbeus C. Kemp and Rufus L. Savage, Jr. (to Texas Co.). U. S. 2,172,560, Sept. 12. An arrangement of app. is described, and a process for the manuf. of high antiknock motor fuel, which comprises stabilizing cracked naphtha to remove therefrom substantially all hydrocarbons of less than 5 C atoms, thereby producing a stabilized cracked naphtha of lower volatility than com. gasoline and a normally gaseous hydrocarbon fraction contg. butane, isobutane and olefins, subjecting the fraction to the action of concd. H_2SO_4 whereby the isobutane is alkylated by the olefins to produce high antiknock normally liquid hydrocarbons within the gasoline-boiling range, sepg. the normally liquid hydrocarbons from residual normally gaseous hydrocarbons, fractionating the residual normally gaseous hydrocarbons to produce a fraction rich in normal butane and a fraction rich in isobutane with the stabilized naphtha to increase its volatility and recycling the fraction rich in isobutane to the alkylation operation. Cf. *C. A.* **33**, 8395[2].

Pitches from coal and petroleum tars. Wilfred M. Bywater (to Barrett Co.). U. S. 2,174,184, Sept. 26. An arrangement of app. is described, and a method of producing from coal and petroleum tars, pitches of lower temp. susceptibility than ordinary tar pitches of the same m. p. comprising suspending finely pulverized coal in regulated amt. in a liquid comprising coal tar or petroleum tar, or its distn. products, which liquid is capable of forming pitch on distn., agitating the liquid and mechanically suspended coal, recirculating the liquid and coal through a heating coil to effect the decompn. of the coal, and continuing the decompn. process until a pitch product of the desired m. p. and temp. susceptibility is obtained.

Apparatus for generating gas from coal, etc. Ernst Mahlkuch. Ger. 679,858, Aug. 14, 1939 (Cl. 24*e*. 3.03).

Apparatus for generating water gas from solid fuel. Braunkohlen- und Brikett-Industrie A.-G. "Bubiag." Ger. 679,961, Aug. 18, 1939 (Cl. 26*a*. 5).

Chamber furnace for producing gas and coke. C. Otto & Co. G. m. b. H. Ger. 679,872, Aug. 17, 1939 (Cl. 10*a*. 13).

Water gas. Willy Linder (to Koppers Co.). U. S. 2,172,740, Sept. 12. An arrangement of app. is described, and a process of continuously producing water gas free of hydrocarbons from distillable solid fuels, which comprises maintaining in a bed of continuously descending fuel a lower water-gas-reaction zone and an upper predistn.

dispersion may be replaced by an aq. emulsion of pine tar or a polyvalent metal salt. The latex compd. may be made heat-sensitive by the addn. of polyvalent metal salts, disubstituted guanidines or an NH_4 salt of a strong acid and ZnO. In the case of a heat-sensitive latex that is not coagulable at normal temps., the compd. may be heated *in situ*, e. g., by playing hot steam on the joint, to produce more or less immediate gelling. 1

Coating compositions. Granitese (Great Britain) Ltd., Grenville J. Staples and James C. B. McGuffie. Brit. 508,025, June 23, 1939. A cold-glazing prepn., for application to brick, stone, concrete, plaster, etc., comprises a mixt. of portland cement and an aq. emulsion of china-wood oil. A pigment may be added. The surface to be treated is preferably first set with a mixt. contg. sand, portland cement and a waterproofing agent and the glazing prepn. is then sprayed thereon. After hardening, the glaze may be coated with a waterproofing medium, e. g., an emulsion contg. H_2O, beeswax, K_2CO_3 and fish glue.

Artificial stone. Louis Czajko. Ger. 679,920, Aug. 16, 1939 (Cl. 80*b*. 17.05). A mixt. of disintegrated asbestos fiber, cement and other optional materials is moistened in a rotating drum and molded under pressure to form stone slabs. 2

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER AND A. GEORGE STERN

Calculating water in combustion of gaseous fuels. J. F. Anthes. *Gas Age* 84, No. 8, 67–8(1939).—A 10-cc. sample of gas mixed with a measured vol. of air is exploded or burned by slow combustion. The contraction is noted and the amt. of CO_2 and excess O are detd. A sample of the same gas is analyzed for CO_2, CO, O and illuminants. The cu. ft. of water vapor per cu. ft. of gas burned = 2{[(0.209 × cc. air used per 10 cc. gas burned − cc. excess O)/10 − 0.5 cu. ft. of CO per cu. ft. of gas + cu. ft. O per cu. ft. of gas] − [(cc. CO_2 produced per 10 cc. gas burned)/10 − cu. ft. of CO_2 per cu. ft. of gas − cu. ft. of CO per cu. ft. of gas]}. Joseph H. Wells

The vegetable oils as Diesel motor fuels. B. Ilieff. *Österr. Chem.-Ztg.* 42, 353–6(1939).—The uses of sunflower oil, cotton oil and olive oil as Diesel motor fuels are discussed. Sunflower oil and cotton oil can be sprayed equally as well as gas oil. The olive oil could not be sprayed. The sprayed pure oils could not be ignited by an open flame but a small addn. of gas oil improves the ease of ignition. The action of the motor with sunflower oil and cotton oil is as stable as with gas oil. The fuel requirements are greater with the vegetable oils than with gas oil. In relation to the max. power, the vegetable oils and the gas oil are equiv. By continued use of sunflower oil, the atomizer becomes clogged but this can be overcome by the addn. of a few % of alc. Olive oil with 15% alc. can be readily sprayed and ignited but the fuel requirement is higher than with the other vegetable oils. Olive oil contg. 30% alc. causes stoppage of the atomizer. The best results are obtained by a mixt. of 36% olive oil, 60% cotton oil and 4% alc. The vegetable oils show a higher efficiency than gas oil. Joseph H. Wells 5

New points of view concerning the ignition process in the Diesel motor. Karl Zinner. *Z. Ver. deut. Ing.* 83, 1073–9(1939).—A review, with 46 references. Five new photographs show (1) the rapid (3×10^{-5} sec.) dispersion of part of the injected fuel into very small drops, (2) the wide spread of the fuel spray during the ignition lag and (3) the decrease in rate of burning from the moment of ignition on. H. A. Beatty

A proposal for the evaluation of coal-cleaning processes. W. Riebeck. *Glückauf* 75, 213–19(1939).—Lab. tests were made to det. the relation between sepg. d., distribution and grain size for various coal-cleaning processes and the results were plotted in a simple form. Information obtained from the graphs is used to indicate the most economical method for coal sepn. L. P. Rockenbach

Sulfur study of some Tertiary coals of Khasi Hills, Assam. N. N. Chatterjee. *Quart. J. Geol., Mining Met. Soc. India* 10, 135–41(1938).—Proximate analyses of coals from Cherapunji, Laitringow and Thanginat are given with addnl. detailed data on S content. Big lumps of pyrites were picked out and eliminated before the coals were analyzed. S retained by the coke is very high and these cokes are not suitable for metallurgical operations. J. F. Schairer

The effect of grinding and blending coal on the coke quality. Hans Siebel. *Gas- u. Wasserfach* 82, 721–6, 736–41(1939).—The purpose of these tests was to det. the best size and proportion of the various available coals to be used for making the most suitable coke for central heating plants and ovens. The coals tested included nut and small Ruhr high-volatile coal, small, nut and single Durham coal, and Yorkshire smalls. The tests made on each coal included petrographic examn., caking test, crucible coking test and carbonization in the Jenkner retort, followed by qual. and quant. examn. of the coke structure and friability. The carbonization and coke-quality tests were repeated on a large no. of blends and the results of 23 tests are tabulated. As a result of the petrographic examn. and a study of the coke properties it was detd. that the Durham and Yorkshire coal (with one exception) should be ground to pass a 3-mm. sieve while one Durham small coal and the high-volatile Ruhr nut and fine coal should not be ground. Relative coke density was found to be satisfactorily estd. by an examn. of prepd. sections (d. was also detd. gravimetrically). It was found that suitable grinding and blending of the coals greatly improved the quality and permitted the utilization of poorly coking coals, even high-inert nut coal, to be carbonized to a satisfactory coke. Mills and accompanying plant are briefly discussed. R. W. Ryan 4 6

Synthetic plastics and the gas industry. Albin Marty. *J. usines gaz* 56, 420–2(1939).—A brief review on coumarone-indene and styrene resins and their uses. B. J. C. van der Hoeven

Fuel gas. Tests of gas engines. A. Pignot. *Chaleur et ind.* 20, 511–16(1939); cf. Larivière, *C. A.* 33, 8958[8].—Difficulties in accurate detn. of engine combustion efficiency are discussed. H. A. Beatty 7

Enriching producer gas. I. M. Rafalovich. *Vestnik Inzhenerov i Tekh.* 1939, No. 9, 388–91.—Various methods of removing CO_2, H_2S and SO_2 from producer gas by phys. and physicochem. means are briefly discussed. The Girdler method (cf. U. S. pat. 2,065,112, *C. A.* 31, 841[8]) is considered the most satisfactory. B. Z. Kamich

Colored gas flames. J. E. Hovingh and J. de Vries. *Gas- u. Wasserfach* 82, 703–4(1939).—Colored gas torches for street illumination were prepd. by placing in the flame a refractory first impregnated with the desired salt and then coated with the solid salt. However, the intensity of the color soon decreased owing to fusion of the salt; this was remedied by causing a fine stream of water to fall on the refractory. For longer periods, better results would be secured by introducing a steady slow stream of a soln. of the desired salt into the flame, using an all-glass system for handling the soln. so as to avoid contamination. R. W. Ryan 8 9

Experiences with dry (sulfur) purification of gas. II. Hermann Deneke. *Gas- u. Wasserfach* 82, 687–9(1939).—In the previous article (*C. A.* 32, 3127[6]) it was shown that the efficiency of gas purification was increased by rearranging the purifier boxes so that the gas velocity through each layer was increased by placing a no. of layers in series.

This study was continued on a practical basis, confirming earlier findings. The boxes were grouped in 2 series, pre-purification and after-purification. In the pre-purifier boxes it was possible to reach a S content of 55% before discarding the purifying material as against 48% in previous practice. In a new plant the boxes would be designed so that the after-purifiers could be placed in the pre-purification state after partial fouling. The change in gas velocity through the purifier boxes had no effect on final O concn. of the gas; this was high owing to leaks at retort doors. R. W. Ryan

Gas for syntheses from peat. A plant trial in the Tiefstack plant of the Hamburg gas works. Gustav Keppeler. *Chem. Fabrik* **1939**, 457–62; cf. *C. A.* **33**, 1911[8], 5630[9].—The Pintsch-Hillebrand process for producing water gas is discussed, and a vertical section through the producer, a flow-sheet and an elevation of the plant are shown. The app. was used on ordinary raw peat contg. 28–30% H_2O, which was charged just after using lignite briquets, the expts. beginning about 70 hrs. after starting to charge the peat, with temps. of 1200 and 1300°. Data are given on heat balance, peat consumption, gas yields and analyses, the latter averaging about 15, 27, 54, 2.5 and 1.8% CO_2, CO, H, CH_4 and N, resp. Estd. plant and production costs based on Pintsch data are given, and it is concluded that a synthetic gas plant is feasible in peat regions. Five references. J. H. Moore

The clinker problem in small gas producers. R. Rasch. *Glückauf* **75**, 239–42(1939).—A study of the clinker problem in small gas producers for motor vehicles has shown that the melting property of the ash in connection with the "fire-clay refractory" is dependent upon the CaO content. Ash low in CaO has little effect upon the refractory, but because of its high soly. effect forms clinkers. For this type of fuel, water-cooled producers are preferable. High CaO content retards the formation of clinker, so that for such fuels a producer lined with fire clay is best. L. P. Rockenbach

Determination of hydrogen sulfide and hydrocyanic acid in manufactured gas. Theo Payer and Adolf Lehrenkrauss. *Gas- u. Wasserfach* **82**, 713–15(1939).—When an attempt is made to apply the Tutweiler I titration method to the detn. of small amts. of H_2S in purified manufd. gas, erroneous results are obtained owing to HCN forming ICN. The method has been modified to give more accurate results and also to permit the detn. of HCN as well. When HCN is not to be detd. starch soln. is added to approx. 500 cc. of gas in the Tutweiler app. and the soln. titrated to faint permanent blue with 0.01 gas-normal I soln. (1 cc. of a gas-normal soln. = 1 cc. of gas constituent to be detd., under standard conditions). The Tutweiler app. is then washed out into a flask and 1 cc. of fresh 5% KI soln. added, after which the soln. is acidified with a little dil. HCl. The soln. is then titrated with 0.01 gas-normal $Na_2S_2O_3$ solution. This titration is subtracted from the first to give the value for H_2S, and when this difference is multiplied by 2.84 the product is g. of H_2S per 100 cu. m. For detn. of HCN, the method is modified by adding a known excess of I soln. to the Tutweiler app. after the faint blue color appears. Results for HCN by this method check well with those by the Feld method. R. W. R.

Supervision of [Diesel] exhaust gases. H. Kuhlman. *Glückauf* **75**, 350–1(1939).—The CO content of a Diesel exhaust can be rapidly detd. by means of a Drager type T-CO measuring app. This outfit employs a catalytic cartridge which rises in temp. as air contg. CO is passed through it. From a linear relationship between temp. and CO content the exact amt. of CO is detd. L. P. R.

Carbon monoxide content in Diesel exhaust. H. H. Müller-Neuglück. *Glückauf* **75**, 337–46(1939).—The formation of CO is affected by the ignition characteristics and chem. compn. of the oil, faults of injection or other mech. defects. A complete review of the methods of obtaining and analyzing samples of mine air and Diesel exhaust is given. A ventilating air supply of 6 cu. m. (215 cu. ft.) per h. p. per min. provides a large margin of safety above the toxic limit. L. P. Rockenbach

Condensation of moisture from boiler flue gases. A. C. Walshaw. *Eng. Boiler House Rev.* **53**, 307(1939).—Calcn. of the temp. at which moisture (and subsequent corrosion from acid solns. formed) will be deposited from flue gases involves (1) estn. of the partial pressure of water vapor in the gases, and (2) use of steam tables to find the corresponding satn. temp. George Ayers

Refining regenerator gas tar by thermal treatment. A. Jäppelt and A. Steinmann. *Glückauf* **75**, 596–601(1939).—The tar obtained from the distn. of poor- or non-coking coals in regenerator-type coke ovens is not suited for use as fuel oil without some treatment such as hydrogenation or distn. Expts. with these tars have shown that by reheating up to about 370° there is a decrease in sp. gr. and viscosity. Above this temp. the sp. gr. and viscosity increase rapidly and the tar acid yield decreases. The effect of time of heating on the tar is also important. Seven sec. appears to be the optimum time of heating. Tar thus treated at a comparatively low cost has the same ignition pt., higher heating value and lower sp. gr. and viscosity than the original tar and does not change appreciably during long periods of storage. L. P. R.

Portable app. for analysis of mine gases, motor exhaust, etc. (Schmidt) **1**. Colorimetric detn. of CS_2 [in motor fuel] (Demann, Adelsberger) **7**. Isolation of 2,2-dimethylbutane from natural gas (Hicks-Bruun, *et al.*) **10**. Coal deposits of the Eastern Urals (Shekhunov) **8**. Amino glycols [for absorbing CO_2 and H_2S from industrial gases] (U. S. pat. 2,174,242) **10**. C black and CO-H gas mixts. from natural gas, etc. (U. S. pat. 2,173,695) **18**. Drilling gas wells (U. S. pat. 2,174,027) **22**.

Motor fuel. Lebbeus C. Kemp and Rufus L. Savage, Jr. (to Texas Co.). U. S. 2,172,560, Sept. 12. An arrangement of app. is described, and a process for the manuf. of high antiknock motor fuel, which comprises stabilizing cracked naphtha to remove therefrom substantially all hydrocarbons of less than 5 C atoms, thereby producing a stabilized cracked naphtha of lower volatility than com. gasoline and a normally gaseous hydrocarbon fraction contg. butane, isobutane and olefins, subjecting the fraction to the action of concd. H_2SO_4 whereby the isobutane is alkylated by the olefins to produce high antiknock normally liquid hydrocarbons within the gasoline-boiling range, sepg. the normally liquid hydrocarbons from residual normally gaseous hydrocarbons, fractionating the residual normally gaseous hydrocarbons to produce a fraction rich in normal butane and a fraction rich in isobutane with the stabilized naphtha to increase its volatility and recycling the fraction rich in isobutane to the alkylation operation. Cf. *C. A.* **33**, 8395[2].

Pitches from coal and petroleum tars. Wilfred M. Bywater (to Barrett Co.). U. S. 2,174,184, Sept. 26. An arrangement of app. is described, and a method of producing from coal and petroleum tars, pitches of lower temp. susceptibility than ordinary tar pitches of the same m. p. comprising suspending finely pulverized coal in regulated amt. in a liquid comprising coal tar or petroleum tar, or its distn. products, which liquid is capable of forming pitch on distn., agitating the liquid and mechanically suspended coal, recirculating the liquid and coal through a heating coil to effect the decompn. of the coal, and continuing the decompn. process until a pitch product of the desired m. p. and temp. susceptibility is obtained.

Apparatus for generating gas from coal, etc. Ernst Mahlkuch. Ger. 679,858, Aug. 14, 1939 (Cl. 24*e*. 3.03).

Apparatus for generating water gas from solid fuel. Braunkohlen- und Brikett-Industrie A.-G. "Bubiag." Ger. 679,961, Aug. 18, 1939 (Cl. 26*a*. 5).

Chamber furnace for producing gas and coke. C. Otto & Co. G. m. b. H. Ger. 679,872, Aug. 17, 1939 (Cl. 10*a*. 13).

Water gas. Willy Linder (to Koppers Co.). U. S. 2,172,740, Sept. 12. An arrangement of app. is described, and a process of continuously producing water gas free of hydrocarbons from distillable solid fuels, which comprises maintaining in a bed of continuously descending fuel a lower water-gas-reaction zone and an upper predistn.

zone, and withdrawing the hydrocarbon-free water gas from the fuel bed at a zone intermediate the upper distn. zone and the lower water-gas zone; introducing the fuel to be degasified at the top of the bed and withdrawing the residue as solids from the bed below the water-gas-reaction zone; and effecting the maintenance of the zones of the fuel bed by traversing the upper distn. zone with a preheated gaseous heat-carrier medium and circulation of the medium from the upper distn. zone together with hydrocarbons therefrom and steam through a sep. gas heating-up stage to reheat the medium and thence back to the fuel bed through the lower water-gas-reaction zone for the water-gas-reaction therewith; and which involves: introducing the gaseous heat-carrier medium for each of the upper and lower zones as sep. streams individual to the respective zones, and independently of the other zone, and in quantities for the respective zones to supply the heat for the respective zones by the sep. streams therefor.

Catalytic purification of gases. Walter H. Groombridge and Ronald Page. Brit. 507,593, June 19, 1939. Gas mixts., particularly CO and H, are freed from S by passage at an elevated temp., e. g., 400–600°, over a catalyst comprising Fe_2O_3 and ZnO, e. g., Fe_2O_3 60–80 and ZnO 40–20%. In the gas of gas mixts. such as water gas the ratio between CO and H may be altered to make the product suitable for conversion into CH_4 or higher hydrocarbons or oxygenated compds. such as aliphatic alcs. by conducting the process with the addn. of H_2O vapor. Where possible, the catalytic treatment is preceded by a washing with alkali soln. to remove as much as possible of the S, and it is followed by a similar washing to remove the remaining S.

Centrifugal gas cleaners. Leon Thuillard. Brit. 507,243, June 13, 1939. Gases are cleaned from impurities by being subjected to centrifugal action and then to passage through a decelerating zone before being discharged to the atm.

Acetylene, etc Johann Schwarz. Ger. 679,885, Aug. 18, 1939 (Cl. 26*b*. 44.01). A mixt. of C_2H_2 and other gaseous hydrocarbons, suitable for use as fuel for motors, is obtained by adding a mixt. of liquid hydrocarbons and alc. or ketones to the CaC_2 and generating the C_2H_2 by adding water. App. is described.

Oven for coking coal. Firma Carl Still. Ger. 678,407, July 14, 1939 (Cl. 10*a*. 19.01). Addn. to 632,850 (*C. A.* **31**, 244[5]). A device for leading off the gases and vapors is described.

Regenerator unit for coking-retort oven. Heinrich Koppers (to Koppers Co.). U. S. 2,172,736, Sept. 12. Various structural features.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER AND STEWART S. KURTZ, JR.

The determination of the aromatic hydrocarbons in the middle fractions of petroleum. Costin D. Nenitzescu, Dimitrie A. Isăcescu and Alexandru C. Isopescu. *Österr. Chem.-Ztg.* **42**, 350, 352–3 (1939). The fraction of petroleum from Gura-Ocnitei b. 150–260° contains 28% aromatic hydrocarbons b. between 200° and 260°. Prehnitol, α- and β-methylnaphthalene, 2,6- and 1,6-dimethylnaphthalene were identified. The presence of 2,7-dimethylnaphthalene is indicated. Joseph H. Wells

Naphthenic acids (from Grozny petroleum). I. I. Lapkin. *J. Gen. Chem.* (U. S. S. R.) **9**, 1332–41 (1939).—Based on the elementary compn. of the Me esters, a mixt. of naphthenic acids, b_4 138–230°, obtained from Grozny petroleum contained: monocyclic C_{10} and C_{11} acids, a mixt. of mono- and bicyclic C_{12} and C_{13} acids and bicyclic C_{14}–C_{18} acids. The presence of tri- and polycyclic acids could not be demonstrated. Detn. of the max. crit. temp. of soln. in aniline of the hydrocarbons obtained by reduction of the naphthenic acids revealed the absence of fatty acids. From the parachor values obtained for the Me esters the presence of 5- and 6-membered nuclei was indicated. Based on the rate of etherification with iso-BuOH (Menshutkin, *J. Russ. Phys. Chem. Soc.* **12**, 82 (1880)) all of the acids contd. a primary CO_2H group. 24 references. John Livak

Power and steam plants for oil-refinery service. C. E. Steinbeck. *Trans. Am. Soc. Mech. Engrs.* **61**, 733–40 (1939). E. H.

Calculation of internal reflux when superheated steam is used in distillation. S. M. Volokh. *Neftyanoe Khoz.* **1938**, No. 9, 29–33.—Calcns. dealing with petroleum bubble towers. A. A. Boethlingk

Gasolines with high nondetonating power, their character, practical interest and manufacture. IV. Industrial processes for the manufacture of gasolines by polymerization. Y. Mayor. *Rev. industrielle* **69**, 305–6 (1939), cf. *C. A.* **33**, 9610[8].—The catalytic process of the Universal Oil Products Co. is described. **V. Trend of recent investigations.** *Ibid.* 306–8.—Fuels with higher octane nos. than those obtained by the preceding processes can be made by (1) adding antidetonating agents to gasoline, and (2) blending gasoline with synthetic materials such as isooctane or isopropyl ether. $PbEt_4$ may be added to the latter blends in order further to increase the octane no. George Ayers

Chemical composition and detonation properties of shale gasoline. N. V. Ershov. *J. Applied Chem.* (U. S. S. R.) **12**, 867–9 (in French, 870) (1939).—The gasoline (octane no. = 70) obtained from the Gdovsk kukkersite belongs to the olefin-paraffin gasoline and has the following compn.: unsatd. 62.0, aromatic 11.4, naphthenes 8.0 and paraffins 18.6%. The gasoline was fractionated into 16 fractions (5° interval) from 40 to 130° and an octane no. and sp. gr. of each fraction was detd. An octane no of gasoline freed from unsatd. and aromatic substances was also detd. Conclusions: The carrier of antidetonation properties of the shale gasoline is the low boiling fraction (according to the phys compn.) and unsatd. hydrocarbons (according to chem. compn.) A. A. Podgorny

The electrical properties of kerosene. B. M. Hokhberg and M. V. Glikina. *J. Tech. Phys.* (U. S. S. R.) **9**, 730–6 (1939).—By purifying kerosene with H_2SO_4, with clay or cement it is possible to increase its specific resistance ρ to 10^{14} ohm cm. at 50 kv./cm. or 10^{13} ohm cm. at 120 kv./cm. Acidity of kerosene up to 10 mg. KOH per g. does not affect ρ. Humidity decreases it. The breakdown voltage of purified kerosene is 230–280 kv./cm. J. J. Bikerman

Selecting solvents for dewaxing residual oils from Surakhany and Koschaguyl crude oils. V. K. Lebedeva, A. V. Druzhinina and E. E. Pisarevskaya. *Neftyanoe Khoz.* **1938**, No. 12, 31–5.—Extn. with MeEtCO in a mixt. with aviation gasoline, acetone in aviation gasoline and a chlorinated solvent in aviation gasoline gives yields of oil decreasing in that order. These solvents when applied at −30° may produce oils of pour point −27 to −29°. These oils usually have a lower viscosity index than oils of higher pour point. The quality of the oil and its yield are lowered when the contents of MeEtCO, acetone and chlorinated solvent in the extn. mixt. are above 35%. The exact nature of the chlorinated solvent is not stated. A. A. Boehtlingk

Improvement of natural lubricating oils. Franz Krczil. *Chem. App.* **26**, 220–2, 237–9 (1939).—Lubricating properties of oils can be improved by addn. of small amts. of polymerization products of high viscosity. Methods for producing products of such high viscosity are described. G. W. Stroebe

Bituminous materials and their uses in the electrical industry. R. Heilmann. *Rev. gén. élec.* **46**, 229–34 (1939).—Classifications and definitions of terms and compns. as used in England, France and America, the characteristics of bituminous materials at different temps., their plasticity, ductility, adhesiveness and melting behavior

are described in detail and testing methods for their properties and those of mixts. are discussed.
M. Hartenheim

Recovering valuable products from spent soda used in petroleum refining. Hans G. Vesterdal (to Standard Oil Development Co.). U. S. 2,174,023, Sept. 26. Residual materials obtained from the neutralization of an acid oil, as by use of NaOH, are treated with a gas contg. CO_2 to remove substantially free alkalies as bicarbonates and to produce a sepn. into an oily layer and an aq. layer contg. the bicarbonates, and an oil and a wetting agent are recovered separately from the oily layer.

Cracking and hydrogenating oils. I. G. Farbenindustrie A.-G. Brit. 507,999, June 23, 1939. Divided on 503,602 (*C. A.* **33**, 7552[4]). Nonknocking motor fuels are obtained by subjecting paraffin hydrocarbons together with C_6H_6 and (or) its light-boiling homologs and (or) light-boiling hydroaromatic hydrocarbons to a heat-treatment at 300–700°, preferably in the presence of a rigid catalyst having a splitting, and advantageously polymerizing, action and, if desired, in the presence of H. Light-boiling homologs of C_6H_6 and light-boiling hydroaromatic hydrocarbons are those boiling in the boiling range of benzines, i. e., up to 225°. In an example, BuH, C_6H_6 and H at 530° and under 250 atm. pressure are led over a splitting and polymerizing catalyst comprising H_2MoO_4, ZnO and MgO to obtain a liquid product the fraction of which boiling up to 180° may be used to improve the nonknocking properties of motor fuels.

Cracking and polymerization of hydrocarbons such as those from oil cracking. Peter J. Gaylor (to Standard Oil Development Co.). U. S. 2,174,024, Sept. 26. An arrangement of app. is described, and a process for the production of liquid hydrocarbons of the gasoline-boiling range from a mixt. of normally gaseous hydrocarbons ranging from CH_4 to C_4H_{10} and including relatively small amts. of butylenes and larger amts. of C_3H_6 and C_2H_4, which comprises subjecting the gas mixt. to cracking at a temp. between about 480° and 800°, passing the cracked products through a polymerization zone maintained at a temp. of 400–565° and under a pressure ranging from 600 lb. per sq. in. to 3000 lb. per sq. in., removing the polymers so formed boiling within the gasoline range and higher, and subjecting the resulting gas mixt. to a temp. of 700–1200° at substantially atm. pressure in the absence of C-forming substances, and recovering the polymers so formed boiling within the gasoline range and higher.

Cracking and coking oils. Universal Oil Products Co. Brit. 507,389, June 14, 1939. In a multi-stage process for cracking and optionally coking oils, the gasoline produced in the process is stabilized, a cooled condensate produced in the fractionation of the cracked vapors is used to absorb rich gases set free in the stabilization and the thus enriched condensate is fed as cooling medium to 1 or more points in the cracking system between the conversion zone and the fractionation zone. App. is described.

Polymerizing olefins such as those from oil cracking. Sumner H. McAllister (to Shell Development Co.). U. S. 2,174,247, Sept. 26. A process for producing olefin polymers comprises maintaining a hydrocarbon mixt. contg. different olefins of at least 3 C atoms at least one of which is a tertiary olefin in contact with an aq. soln. of a strong inorg. S acid of 55 to 80% concn. at a polymerizing temp. of about 120 to about 70° until substantial conjunct polymerization between the olefins takes place. Polymerization products may thus be obtained which constitute antiknock motor fuels.

Liquid hydrocarbons from normally gaseous hydrocarbons such as those from oil cracking. Pike H. Sullivan (to Process Management Co.). U. S. 2,173,456, Sept. 19. An arrangement of app. is described, and a method of converting normally gaseous hydrocarbons to normally liquid hydrocarbons including gasoline constituents which comprises subjecting normally gaseous hydrocarbons to elevated conditions of temp. and pressure to effect conversion thereof to normally liquid hydrocarbons, sepg. the products of conversion into a gaseous phase and a liquid phase including the normally liquid constituents of the conversion products, passing at least a portion of the normally gaseous hydrocarbons thus sepd. through a primary scrubbing zone in intimate contact with a scrubbing medium consisting of normally liquid hydrocarbon oil, admixing enriched scrubbing medium from the primary scrubbing zone with the hot products of conversion to cool the hot products, passing unabsorbed gases from the primary scrubbing zone through a secondary scrubbing zone in intimate contact with a scrubbing medium consisting of liquefied normally gaseous hydrocarbons, and subjecting enriched liquid scrubbing medium from the secondary scrubbing zone to the elevated conditions of temp. and pressure. Cf. *C. A.* **33**, 3579[2].

Hydrocarbon synthesis. Metallgesellschaft A.-G. and Wilhelm Herbert. Brit. 507,366, June 14, 1939. In the synthesis of hydrocarbons, mainly paraffinic and olefinic, from CO and H with catalysts known for the synthesis of benzene, oil and solid paraffin and at temps. below those yielding only CH_4, the gas throughput is kept greater than 1 l. (calcd. at normal pressure and temp.) per hr. per g. of hydrogenating metal in the contact mass and the reaction chamber or the pressure, or both, is made so large that the time of contact of the gas with the contact mass is greater than 45 sec. while the temp. is so regulated that the heat generated, calcd. as heat load per sq. m. of cooling surface of the cooling members embedded in the contact mass, at the gas pressure of p atm. does not exceed 500 $\sqrt[3]{p}$ kg.-cal. per hr. Recycling of gases, if desired after removal of reaction products, increases the catalyst life and reduces the formation of solid paraffin. Among examples, a Co-Th-kieselguhr catalyst, prepd. by pptg. a mixt. of the metal nitrate solns. and kieselguhr with K_2CO_3, granulating and reducing, and contg. Co 33, ThO_2 6 and kieselguhr 61%, is used; the contact chamber is divided into 2 stages, part of the reaction products being withdrawn immediately; gases contg. H_2 2 to CO 1 vols. are caused to react at 180° and normal pressure, the throughput being 1 l. per hr. per g. of Co, the time of stay 36 sec. and the heat load per sq. m. 240 kg.-cal. per hr.

Apparatus for conserving low-boiling hydrocarbon vapors of centrifuged oil. Hans O. Lindgren (to De Laval Separator Co.). U. S. 2,172,513, Sept. 12. App. is used which includes the combination with a centrifugal separator for refining low-boiling liquid hydrocarbons and collecting vessels surrounding the separator and closed to the atm. and adapted to receive the sepd. constituents and each provided with a single fluid outlet, of a recovery system for condensing condensable hydrocarbon vapors, receivers for the sepd. liquids, closed fluid passages between the respective outlets from the collecting vessels and the respective receivers for conveying to the latter both sepd. liquid constituents and vapors, and a closed vapor passage connecting the vapor spaces of the receivers with the recovery system.

Oil-refining apparatus for use with internal-combustion engines. Johnnie A. Niedens. U. S. 2,173,631, Sept. 19. An engine oil-refining app. includes a casing, a filtering chamber within the casing contg. filtering material and having an inlet communicating with the engine crank case, a vaporizing chamber below the filtering chamber having an outlet for return of oil to the crank case, means for passing oil from the filtering chamber to the vaporizing chamber, an exhaust gas receiving chamber below the vaporizing chamber for heating the latter, a vapor outlet for the vaporizing chamber, and a device such as a float-actuated valve for preventing the escape of oil through such vapor outlet.

Refining paraffin. The Burmah Oil Co. Ltd. and Charles R. S. Harley. Brit. 507,761, June 16, 1939. Paraffin is refined by impregnating a carrier of absorbent and reinforcing material therewith to form a solid film, heating the impregnated carrier and subjecting it to momentary pressure to release and remove the sweats. The carrier may be an endless band of cotton duck or a similar wool fabric and may be heated and pressed at successively higher temps. App. is described.

Obtaining organic compounds from acid sludge of oil refining. Karl Bauer, Waclaw J. v. Piotrowski, Hugo Burstin and Jozef Winkler. U. S. 2,172,784, Sept. 12. App. is described, and a process for obtaining org compds. from sludge such as that obtained by treating mineral oil with H_2SO_4 which comprises melting the fusible org. compds. present by heating the sludge to about 200–300°, and sepg. the molten compds. from the inorg. residue.

Treating gasoline distillates Bernard S. Greensfelder and Monroe E. Spaght (to Shell Development Co.). U. S. 2,174,174, Sept. 26. An arrangement of app. is described, and a continuous process of neutralizing a cracked hydrocarbon distillate contg. a S acid and alkyl phenols, involving treating the distillate with an excess over the equiv. to the S acid of an aq. alkali metal carbonate-bicarbonate soln. contg. small amts. of alkyl phenols under conditions to form an aq. layer contg. an alkali metal salt of the S acid, and a distillate layer substantially free from the S acid contg. alkyl phenols, sepg. the layers and treating the distillate layer with an amt. of aq. alkali metal hydroxide of 30 to 50% concn. slightly in excess of the equiv. of the alkyl phenols to produce an ext. comprising an aq. alkali metal alkyl phenolate soln. and a residual distillate, sepg. the ext. from the distillate, carbonating the ext. to liberate alkyl phenols and to produce an alkyl phenol phase and an aq. carbonate-bicarbonate soln. phase contg. a portion of the liberated alkyl phenols, sepg. the liberated alkyl phenol phase from the resulting aq. soln. phase and returning the latter to treat further amts. of the cracked distillate contg. S acid and alkyl phenols.

Motor fuels from refinery gases. James R. Rose. U. S. 2,173,374, Sept. 19. An arrangement of app. is described, and a process which comprises subjecting petroleum refinery gases contg. saturates and unsaturates to a pressure of 800–1500 lb. per sq. in. and to a cooling action for liquefaction, subjecting the resulting liquid under the pressure mentioned to a cracking temp. of 425–815°, and subjecting the resulting material while under the pressure to a polymerization catalyst which may be formed of carnotite 27, phosphate rock 27, Floridan clay 27, Zn phosphate 5, $BaCl_2$ 4 and fire bond 10 parts. U. S. 2,173,375 relates to a generally similar process, in which the cracked products under pressure are passed in contact first with carnotite and then in contact with a mixt. of phosphate rock, Floridan clay, Zn phosphate, a Ba halide and fire bond in specified proportions. U. S. 2,173,376 relates to catalysts for such use and which may be formed from phosphate rock 10–50, Floridan clay 10–50, Zn phosphate 5–30, a Ba halide 5–30, waterglass 10–40 parts, and carnotite 25–100% of the total wt. of all the other ingredients. Cf. *C. A.* **33**, 8005[8].

Antiknock motor fuel. Sylvan R. Merley (to Power Patents Co.). U. S. 2,173,452, Sept. 19. An arrangement of app. is described, and a process of mfg. a high antiknock motor fuel by bringing unsatd. olefinic hydrocarbons into contact with concd. H_2SO_4, and which comprises continuously introducing a stream composed of a mixt. of liquid hydrocarbons produced by cracking petroleum oil and contg. paraffinic and primary, secondary, and tertiary olefinic hydrocarbons having a boiling range up to approx. 135° into the first of a series of interconnected contact zones, introducing a stream of relatively cool concd. H_2SO_4 into the last of the series of zones, continuously passing the hydrocarbons and H_2SO_4 through the zones countercurrent to each other and in intimate contact with each other in each zone, maintaining the first zone of the series at a temp. of about 20°, and the last zone of the series at a temp. of about 0°, whereby reaction products formed from the hydrocarbons and H_2SO_4 in the last zone of the series are carried with the acid toward the first zone of the series and subjected to gradually increasing temps., thereby converting portions of the olefinic hydrocarbons into higher-boiling products of relatively high octane number, and removing an improved high-antiknock motor fuel product from the last zone of the series.

Antiknock agents for fuels of gasoline boiling range. Standard Oil Development Co. Brit. 507,246, June 13, 1939. Addn. to 445,503 (*C. A.* **30**, 6025[7]) and 504,837 (*C. A.* **33**, 8006[1]). These consist of branched ethers of dihydric or trihydric alcs., which boil above 95°. Aliphatic radicals contg. a tertiary or quaternary C atom are preferred. Glycol ethers specified are mono-*tert*-butyl, mono- and di-isopropyl, isopropyl *tert*-butyl, ethyl or methyl *tert*-butyl, branched mono- and di-amyl ethers with or without Me, Et or iso-Pr groups and branched butyl amyl ethers. The corresponding ethers of propylene- or butylene-glycol may be used. Glycerol ethers specified are of the type $ROR_1(OR_2)OR_3$, where R_1 is an alkyl radical of at least 3 C atoms, R_2 and R_3 are H or alkyl, and R is alkyl. $PbEt_4$ may also be present.

Drilling oil and gas wells. Robert J. Ball. U. S. 2,174,027, Sept. 26. In drilling with the aid of a mud circulation, alginic acid or an alginate such as that of Na is added to the circulation, and serves to give improved wall building and sealing effects.

Extracting materials such as oil-bearing shale. Wm. L. Horner (to Core Laboratories, Inc.). U. S. 2,173,842, Sept. 26. An arrangement of app. is described, and a process for extg. sol. material from pores of a permeable porous noncomminuted structure by inducing circulation of a solvent in the pores comprising the steps of heating the structure to vaporize volatile substances in the pores, subsequently cooling the structure to cause the vapors to condense in the pores while the structure is immersed in a liquid solvent, and repeating the cycle until the extn. is carried to the extent desired. CCl_4 or acetone, etc. may be used as the solvent in the treatment of shale or limestone, etc.

Stripping oil remaining in subterranean oil pockets. Hiram W. Hixon. U. S. 2,173,556, Sept. 19. App. is described, and a method of stripping the oil remaining in a subterranean oil pocket consisting in continuously forcing gas and air under pressure into a closed combustion chamber located above ground, continuously burning within said chamber the gas and air mixt. in jet formation to produce heated fluid products of combustion, conveying the products of combustion by the pressure thus developed therein from the combustion chamber to the oil pocket to effect by the heat thereof the freeing of the oil from the oil-bearing sand and to cause by the pressure thereof the driving of the freed oil toward one or more pumping wells tapped into the pocket and then removing the oil through the pumping wells.

Heat-exchange apparatus (with a contact mass) suitable for oil conversion, etc. Eugene J. Houdry (to Houdry Process Corp.). U. S. 2,173,844, Sept. 26. Various structural features.

Device for taking samples of oil from different depths in storage tanks. Wm. L. Walker. U. S. 2,174,100, Sept. 26. Various structural and operative details.

Blowing asphalt-producing petroleum base materials. Philip Subkow (to Union Oil Co. of Calif.). U. S. 2,172,821, Sept. 12. App. is described, and a process of blowing asphalt-producing petroleum base materials which in-

volves introducing a stream of material to be treated at an elevation into a reaction chamber, sepg. the stream into pools having a gravity downward flow, injecting sep. currents of an oxidizing gas at selected elevations into the reaction chamber, withdrawing the residual gases from the reaction chamber, withdrawing the oxidized petroleum base material from the reaction chamber and recirculating at least a portion thereof through the reaction chamber.

Polymerizing olefins. Jacque C. Morrell (to Universal Oil Products Co.). U. S. 2,172,542, Sept. 12. An olefin-contg. gas such as one from oil cracking, at a polymerizing temp. (suitably about 190–290°), is subjected to the catalytic action of a salt of pryosulfuric acid, such as the Na salt mixed with kieselguhr. Cf. *C. A.* 34, 114[7].

Polymerization of olefins. Standard Oil Development Co. Brit. 508,070, June 22, 1939. *Lubricating oils* are produced by polymerizing an isoölefin while dissolved in at least 10% by vol. (calcd. on the isoölefin when in liquid phase) of a polymer thereof contg. not more than 5 mols. of the isoölefin and in the presence of a Friedel-Crafts catalyst, e. g., BF_3, at −50 to 100°. Thus, isobutene or mixts. contg. it, e. g., a C_4 cut, may be polymerized in di- or tri-isobutene.

Lubricating composition. Chemische Fabrik Flörsheim A.-G. Ger. 676,040, May 24, 1939 (Cl. 23*c*. 1). Addn. to 639,886 (*C. A.* 31, 4107[1]). Blown or thickened fatty oils or castor oil sol. in mineral oil are given an addn. of normally ground graphite and allowed to stand till the graphite becomes colloidal. The product is added to mineral oils.

Lubricating compositions. Standard Oil Development Co. Brit. 507,636, June 16, 1939. A lubricant for use by itself or as an addn. to ordinary lubricating oils consists of a thickened and hydrogenated org. ester or mixt. of esters. The thickening is effected by polymerizing by the influence of heat or voltolization. The hydrogenation is preferably conducted at 100–250° in the presence of an active hydrogenation catalyst, the final product having a viscosity of over 500 sec. at 210°F. The esters are those of polyhydric alcs., or of polybasic acids, or synthetic esters of polyhydroxy compds. such as are obtained by esterifying glycerol or glycol with the acids obtained by the oxidation of wax or with ricinoleic or stearic acid. The esters di-Bu phthalate, tricresyl phosphate or Et dibenzyl malonate are also included. In an example, linseed oil is thickened by heating for 10 hrs. at 575°F. in a glass vessel and the product is partly hydrogenated by treatment with H in the presence of an activated Ni catalyst at 2000 lb. per sq. in. pressure and at 212–225°F.; to remove solid suspended matter, the thick oily product is dissolved in 5 vols. of Et_2O, cooled to −40°F. and filtered.

Sulfurized lubricating compositions. Standard Oil Development Co. Brit. 507,385, June 14, 1939. Lubricants resistant to high pressure are made by treating substantially nonparaffinic solvent ext. concentrate of a petroleum oil with a sulfurizing-agent and blending the product with a lubricating oil of fatty or mineral character. The solvent ext. may be sulfurized by heating to 300–375°F. with free S for a time sufficient to dissolve the S and then rapidly chilling to below 250°F. to prevent further reactions. The blend of oil and sulfurized solvent ext. may be further heated with a sulfurizing-agent. Pb naphthenate may be added to the final product.

Apparatus for testing the quality of lubricating oils used in internal combustion engines. Herman L. Thwaites (to Standard Oil Development Co.). U. S. 2,174,021, Sept. 26. App. used comprises an inverted metal cone having an inclined circumferential groove on its inner surface adapted to allow the oil to be tested to flow slowly on the top of the groove around the inner surface of the cone and through an outlet at the bottom of the cone (which is heated, as by an elec. heater).

Refining oils such as petroleum lubricating oils with solvents such as "chlorex." David F. Renshaw (to Socony-Vacuum Oil Co.). U. S. 2,173,915, Sept. 26. An arrangement of app. is described, and a process of treating oil with a solvent reagent selectively to dissolve and remove therefrom naphthenic constituents comprising the following steps: flowing oil and solvent in countercurrent through a system comprising a plurality of stages each consisting of a contacting step and a settling step, removing from each settling stage an "extract" consisting of naphthenic constituents dissolved in a substantial amt. of solvent, which "extract" is introduced into the stage next preceding in the direction of oil flow, removing an "extract" consisting of naphthenic constituents dissolved in a substantial amt. of solvent from the stage in which oil is first introduced, admixing at least a portion of the "extract" last named with the "extract" withdrawn from the next succeeding stage in the direction of oil flow, and thereby initially bringing the oil to be treated into contact with solvent at a solvent/oil ratio controllably increased over the ratio at which solvent and oil are fed to the system. Cf. *C. A.* 33, 3138[7].

Fractionating hydrocarbon oils such as crude or lubricating oils. Willem R. van Wijk, Willem J. D. van Dijck and Abel J. C. Bart (to Shell Development Co.). U. S. 2,173,460, Sept. 19. A process of sepg. hydrocarbon fractions having m. ps. below that of paraffin wax and contained in a hydrocarbon mixt. which is free from paraffin wax, involves mixing said mixt. with a solvent mixt. contg. a selective solvent which has a preferential solvent action for the less satd. hydrocarbons and at the sepg. temp. is at least partly immiscible with the most paraffinic constituents of the oil, and a soly.-promoting solvent which promotes the miscibility of the selective solvent and the hydrocarbon mixt., and cooling the hydrocarbon mixt. to a temp. between −25° and −125° sufficiently low to solidify a fraction of said mixt. without solidifying the solvent mixt., and sepg. the solidified fraction from the resulting soln. of the unsolidified fraction and the solvent mixt. Acetone or EtOAc, etc., may be used as the selective solvent with toluene, etc. as the "soly.-promoting" solvent (numerous examples being given).

Wax-modifying agents suitable for use in waxy lubricating oils. Eugene Lieber and Martin M. Sadlon (to Standard Oil Development Co.). U. S. 2,174,246, Sept. 26. A process for producing wax modifiers by condensation of chlorinated paraffin wax and aromatic compds. with catalysts of the Friedel-Crafts type, involves prepg. a mixt. of the aromatic compd. and the catalyst in a satd. polyhalogenated hydrocarbon solvent of 2–3 C atoms, adding thereto chlorinated paraffin wax and maintaining the temp. below 93° to effect the reaction, then sepg. the catalytic material.

Chlorinated diphenyl sulfide. Frank M. Clark (to General Elec. Co.). U. S. 2,172,954, Sept. 12. By a described chlorination process, a mixt. of isomers of tetrachlorodiphenyl sulfide is produced which is suitable for use with lubricating oils to increase their load-carrying capacity.

Lubricants. James W. Johnson, Jr. (to Atlantic Refining Co.). U. S. 2,173,117, Sept. 19. A hydrocarbon oil is mixed with about 1–10% of a carboxylic acid ester of a hydroxy ether such as a naphthenic acid ester of diethylene glycol mono-Bu ether, which serves to give improved "oiliness" and viscosity index.

Lubricants. Standard Oil Development Co. Brit. 508,326, June 29, 1939. A cohesive grease consists of oil, 2–20% of Al stearate, a linear polymer thickener of mol. wt. exceeding 800 and glycerol not exceeding 2%. The glycerol may be replaced by polyglycerol or polyglycol. In an example, the grease consists of oil 89.92, Al stearate 8, glycerol 0.08 and polymerized isobutylene of approx. wt. 70,000 2%.

Lubricating greases. Standard Oil Development Co. Brit. 507,980, June 23, 1939. These comprise mineral oil and 10–40% of a mixt. of Na and Ba soaps. The mixt. of soaps consists of 10–1 parts of Na soap to 1 of Ba soap. In an example, stearic acid 425 and a mineral lubricating oil of viscosity 200 sec. Saybolt at 100°F. 500 parts are thoroughly mixed in a grease kettle at 140–150°F.; when the acid has completely melted and dissolved, 25 parts of $Ba(OH)_2$ in approx. satd. aq. soln., are stirred in, the temp. is then raised to about 360°F. while 62 parts of

NaOH (30% aq. soln.) is stirred in and, when sapon. is complete and H_2O substantially completely eliminated, the product is cooled to about 200°F. and worked at that temp. for 2–3 hrs

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Recently developed sources of cellulose. L. G. S. Hebbs. *J. Soc. Dyers Colourists* **55**, 550–9(1939).—A review. In addn. to spruce and hemlock as sources of cellulose, Spanish grass (*Arundo donax*) is a raw material for rayon pulp in Italy, while beechwood is employed in Germany to produce staple fiber. The pulping of reeds and of the stems of the soybean plant has not been encouraging because of the short fiber length (0.6 mm. av.). Fifteen references. W. H. Boynton

X-ray studies of polymer-homolog cellulose fibers. E. Plötze and H. Person. *Naturwissenschaften* **27**, 693 (1939).—Polymer-homolog series of cellulose prepd. by oxidative or hydrolytic demolition were studied by x-ray. Both ramie and cotton fibers were used. The degree of polymerization ranged from 200 to 3000. The Debye-Scherrer diagrams for all of the series were identical; hence the structure was unchanged. A quant. value for the crystallite orientation was obtained (Hosemann, *C. A.* **31**, 8316[4]) by calcg. the half widths of the equator interferences from blackening measurements. The half-width is for ramie 15°, for cotton 32°. B. J. C. van der Hoeven

Preparation of fibrous triacetylcellulose. I-II. I. Sakurada, I. Tukahara and T. Morita. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 252(1939).—Cotton and ramie were acetylated and the effects of temp., amts. of H_2SO_4 and Ac_2O, and type of solvent were studied. An increase in reaction temp. or in the amt. of H_2SO_4 increased the speed of acetylation (I) but resulted in decreased viscosity (II) of the product. The amt. of Ac_2O had no effect on I, but low amts. of the anhydride caused a decrease in II. If the compn. of the acetylating mixt. (C_6H_6, Ac_2O, H_2SO_4) is kept const., the amt. of cellulose used affects neither I nor II. The amt. of AcOH adhering to the cellulose prior to acetylation can be reduced to 30% of the dry wt. of cellulose without effect on I. The type of cellulose influences neither I nor the properties of the acetylated product. Trichloroethylene, monochlorobenzene, nitrobenzene, *o*-dichlorobenzene and petr. ether were compared with C_6H_6 as solvent for the reaction, and trichloroethylene was found to be best suited for this purpose; the cellulose is acetylated more speedily in this solvent and II of the acetylated product is very good. No appreciable difficulties were met on acetylating batches up to 2 kg. at one time. S. I. Aronovsky

The homogeneous saponification of triacetylcellulose by means of sulfuric acid in acetic acid solution. K. Seki. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 253–4 (1939).—Purified triacetylcellulose was dissolved in a 95.72% aq. soln. of AcOH to a concn. of 2.5%. The effects of the H_2SO_4 concn. (0.148–1.44%) and reaction temp. (20°–60°) on the velocity of sapon. were studied. The sapon. reaction takes place according to the unimol. equation, $dx/dz = k(a - x)$, where x represents the degree of sapon. in moles AcOH per 100 moles $C_6H_{10}O_5$, a represents 300 for triacetylcellulose with the theoretical AcOH content, and k is the velocity const. which varies with x. The soln. becomes turbid as the value for x approaches 150. The velocity const. increases with the concn. of H_2SO_4, and with increasing temp. of reaction. The heat of the sapon. reaction was calcd. to be 14.4 kg. cal. per mole AcOH. S. I. Aronovsky

The heterogeneous saponification of fibrous triacetylcellulose by acids, and the solubility of the partly saponified products in acetone. I. Sakurada, I. Tukahara and T. Morita. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 254–5(1939); cf. *C. A.* **33**, 2703[3].—High-viscosity triacetylcellulose was prepd. from cotton linters in trichloroethylene. The acetylated cellulose was sapond. at various temps. (15°–95°), as follows: 20 g. (dry basis) triacetylcellulose was placed in a 1-l. flask with 500 cc. HNO_3 soln. (0.2–5.0 *N*). The Ac content and Me_2CO-soly. were detd. on 2-g. samples taken at various intervals. The heterogeneous sapon. of the acetylated cellulose takes place in accordance with the equation, $x = kz^m$, where x represents the degree of conversion in moles ester groups per 100 moles $C_6H_{10}O_5$, z represents the duration of the reaction, and k and m are consts. The AcOH confent of the acetylcellulose decreases with increase in sapon. time while the Me_2CO-soly. increases in 8 days to a max., at an AcOH content of 57 ± 1%. Lower sapon. temps. favor the increased Me_2CO-soly. of the ester. The heat of sapon. of the acetylcellulose is 14.4 kg. cal., similar to that obtained with homogeneous sapon. S. I. Aronovsky

The degradation of oriented cellulose structures by polarized ultraviolet light. C. W. Mason and F. B. Rosevear. *J. Am. Chem. Soc.* **61**, 2995–3001(1939).—Parallel ramie fibers were irradiated with polarized ultraviolet light in a cell contg. metallic Na to eliminate air or moisture that might cause secondary nondirectional reactions. With light vibrating crosswise of the fiber, degradation was greater than with vibrations lengthwise by about 25%, as measured by the Cu no. detd. on 10-mg. samples. Conclusion: Photochem. degradation of cellulose chains is greatest if they are oriented so that the light energy vibrates in the direction in which they are most deformable. A. B. Garrett

Lignin and related compounds. XLVI. The action of ozone on isolated lignins. Rodger M. Dorland, W. Lincoln Hawkins and Harold Hibbert. *J. Am. Chem. Soc.* **61**, 2698–701(1939); cf. *C. A.* **33**, 7562[2].—Isolated lignins, obtained by extn. with HCO_2H and AcOH, and which are normally insol. in aq. $NaHSO_3$ soln., yield sol. sulfonic acids after a prior treatment of the lignin with O_3. An increase in soly. in aq. $NaHSO_3$ and a decrease in MeO content of HCO_2H lignin take place with increasing ozonization. Sulfonic acids obtained in this manner from birch HCO_2H and AcOH lignins yield vanillin and acetovanillone on alkali cleavage. This is probably the first time that acetovanillone has been obtained from a lignosulfonic acid prepd. from a hardwood. C. J. West

Detection and determination of viscose impurities Ernst Kuhnel. *Kunstseide u. Zellwolle* **21**, 394–8(1939); cf. *C. A.* **34**, 260[5].—By means of photomicrographic illustrations the following impurities that are found by centrifuging are described: incompletely dissolved fibers, undissolved resistant fiber fractions, coagulated viscose particles, cryst. particles such as $CaSO_4$, $CaCO_3$ or SiO_2 and Fe or rust particles. Other photomicrographs and descriptions follow the pulp through every stage of the viscose process and indicate some of the irregularities that may occur. The recommendations may be summarized as follows: (1) detn. of the cause of filtering difficulties, (2) detn. of the optimum amts. of assistants, which may be different for different pulps, (3) detn. of optimum reaction temps., (4) control of the filtering effects of different filtering media by detn. of impurities before and after filtering, (5) detn. of the rate of filtration of viscose, (6) detn. of the optimum soly. of the xanthate, (7) control of mercerization and xanthation and (8) ultimately the possibility of judging the suitability of a particular pulp for viscose prepn. M. Plunguian

Stability of nitrocellulose made from hemp. Mario Tonegutti and Enzo Brandimarte. *Ann. chim. applicata* **29**, 350–6(1939).—Nitrocellulose made from cotton or hemp cellulose has approx. the same stability, both being less stable than the product made from Cl-extd. hemp. Possibly this increased stability is due to a different orienta-

tion of the crystals in the nitrated deriv. of the Cl-treated hemp cellulose. A. W. Contieri

Ten years' experience with industrial hygiene in connection with the manufacture of viscose rayon. H. L. Barthélémy. *J. Ind. Hyg. Toxicol.* **21**, 141–51 (1939).—See *C. A.* **33**, 9627⁶. A. L. Elder

---

Aging phenomena and the mol. size of chain complexes [cellulose derivs.] in soln. (Wehr) **2**. Relation between the refractivity of cryst. cellulose and the temp. (Frey-Wyssling, Wuhrmann) **2**. Fusing and working quartz [making a spinneret for rayon] (Brit. pat. 508,013) **19**. Dyeing, bleaching or other liquid treatments of paper stock (U. S. pat. 2,174,178) **25**. Condensation products [as assistants in rayon industries] (Ger. pat. 676,407) **13**.

Cellulose process. Zellstofffabrik Waldhof (Friedrich W. Kahle, inventor). Ger. 677,084, June 17, 1939 (Cl. 55*b*. 3.40). Addn. to 671,984 (*C. A.* **33**, 6538⁸). The waste SO_2 from sulfite cellulose digesters is completely recovered by releasing the pressure and allowing the sealing liquid of the gasometer to dissolve the liberated SO_2.

Refining cellulosic materials. Johann W. Eggert. Brit. 506,875, June 6, 1939. Straw and other plant materials contg. SiO_2 are subjected to treatment with an aq. soln. of a salt having a reducing action, e. g., Na_2SO_3, at 120–30° to remove all H_2O-sol. constituents. The extn. liquid may also contain a phosphorus salt. The materials are then subjected to treatment with a soln. of NaOH contg. a reducing salt at 140–60°. The lye is subsequently removed rapidly and completely from the treated cellulose while in a hot state. The material may then be subjected at not exceeding 17° to the action of Cl of 0.43–1% concn. in aq. soln. Buffer substances are present during the chlorination to prevent acid formation. The material may then be subjected to a further treatment with alkalies, alk. earths or alk. salts. The final alk. treatment may be effected with concd. alkalies or alk. earth hydroxides at low temp. An antichlor may be added to the soln. and the alkali may then be washed out by means of low-pressure wet steam. The cellulose pulp may be acidified before the last washing process. The pulp may be used for making cellulosic solns.

Hydroxyalkylation of cellulose materials. Aubrey E. Broderick (to Carbide and Carbon Chemicals Corp.). U. S. 2,173,470, Sept. 19. Vapors of an alkylene oxide such as ethylene or propylene oxide are brought into contact with a cellulose such as alpha wood pulp or cotton linters in the presence of a tertiary amine catalyst such as trimethylamine under subatm. pressure and with regulation of the rate of introduction of the alkylene oxide in accord with the rate of its reaction with the cellulose to prevent the pressure from rising substantially above atm. pressure. The products may be readily esterified. U. S. 2,173,471 relates to the reaction of a vaporous alkylene oxide such as propylene oxide with a mixt. of an unmercerized cellulose such as cotton linters contg. about 35–60% of water in the presence of between 0.5% and 8% of an etherification catalyst such as NaOH while the temp. is maintained between atm. temp. and 60° and under a pressure not more than about 6 lb. per sq. in., in the substantial absence of air.

Cellulose derivatives. British Celanese Ltd. Brit. 507,722, June 20, 1939. Cellulose org. derivs. are stabilized by being treated while in a finely divided or dispersed form with a H_2O-insol. nonresinous morpholine compd. The treatment imparts stability against the deteriorating influence of light, heat or industrial gases. The treated substances and articles made therefrom are more resistant to fading or color change when dyed, e. g., with H_2O-insol. aminoanthraquinone dyes. Phenylenedimorpholine, phenylaminomorpholine, phenylmorpholine and *p*-hydroxyphenylmorpholine may be used. The morpholine compd. may be dispersed in an aq. medium which may also contain a mono- or poly-hydric alc.

Cellulose derivative and regenerated cellulose shims for milling-machines. Arthur Schoenwerk. Brit. 508,111, June 27, 1939. Shims or spacers of annular shape as used in milling operations when mounted on milling arbors are made from film, ribbon, foil, plate, etc., of cellulose acetate, celluloid or other cellulose ester or ether, or regenerated cellulose such as that obtained from viscose.

Alkali cellulose. Schlesische Zellwolle A.-G. Brit. 508,338, June 29, 1939. Matured alkali cellulose is produced by subjecting cellulose pulp, obtained by the alk. digestion of wood, straw, etc., in the highly dild. condition in which it leaves the digester, to extn., alkalization, pressing, disintegration and maturing in a continuous working operation. App. is described.

Apparatus for the manufacture of alkali cellulose, etc. Wilhelm Grötzinger (to Baker Perkins Co.). U. S. 2,174,241, Sept. 26. App. for the manuf. of alkali cellulose and the like comprises in combination a conveyor having a horizontal treating run and a return run, containers for cellulose material mounted on the conveyor, a vat for treating soln. beneath the treating run through which the conveyor carries the containers in a step-by-step travel, means for pressing excess soln. from the cellulose after it passes through the vat and for discharging the cellulose from the containers.

Apparatus for production of cellulose xanthate from alkali cellulose and carbon disulfide. Teunis Dokkum (to American Enka Corp.). U. S. 2,174,056, Sept. 26. Various structural and operative details.

Cellulose ethers and xanthates. Leon Lilienfeld. Brit. 507,137, June 7, 1939. Cellulose ethers that are wholly or partially sol. in caustic alkali soln. and insol. or sparingly sol. in H_2O and are incapable of forming films, or incapable of forming films of practical value, are prepd. by treating an alkali-sol. alkyl, hydroxy-alkyl or hydroxy-acid cellulose ether, or a cellulose ether obtained from halo-olefins, with a hydrolyzing or degrading and (or) oxidizing agent until the desired product is obtained. The products obtained may be xanthated. The products, or the xanthated products, may be applied, in the form of a soln. or paste, to a fibrous material, e. g., a textile material, if desired together with other finishing, impregnating, dressing, coating, filling, weighting, printing or sizing agents. When the product is applied from soln. it may be further treated with a pptg. or coagulating agent, e. g., H_2O or a soln. of an alkali carbonate. Textile materials treated by the process are not impaired as regards their feel and appearance even in the absence of softening agents or when applied in large amts. In an example, a cellulose ether prepd. according to any 1 of 30 processes cited is mixed with HCl of 0.5% concn. and heated to 50–100°, the product is dissolved in NaOH soln. at from 5° to −10°, applied to a woven fabric and coagulated in a pptg. bath. Other examples illustrate the use of HCl of 0.05, 0.1, 0.2, 1 and 2% concns., H_2SO_4, chloride of lime and of alk. and neutral $KMnO_4$ in the process.

Cellulose ethers. Desmond C. Mandeville, Albert A. Houghton and Imperial Chemical Industries Ltd. Brit. 507,203, June 6, 1939. Low-substituted cellulose ethers are obtained by the actn. of a liquid etherifying medium in the form of a fine mist, an atomized soln. or an atomized emulsion in a suitable liquid medium to comminuted and agitated alkali cellulose. The cellulose ethers so produced may be subjected to further alkylation to produce H_2O-sol. forms. Among examples, comminuted sulfite wood pulp is added to a soln. of NaOH in a shredding machine; after some hrs. a soln. of ethylene chlorohydrin in H_2O is atomized into the machine for 2 hrs. and the temp. then gradually raised to 30°; the product is aged, acidified, centrifuged and washed; it dissolves completely in 7.5% NaOH soln. when cooled to −7° with subsequent gradual rise of temp.

Preparing cellulose for esterification. Courtaulds Ltd. and John P. Stoneman. Brit. 507,946, June 23, 1939. The cellulose is treated with a little concd. HCOOH, not more than 1 part of acid to 1 of cellulose, at above 50° under conditions that prevent loss of HCOOH; uncombined HCOOH is removed and the pretreated cellulose is then dried and is finally esterified. Uncombined HCOOH

is removed by evapn. or by washing with a liquid in which the acid is sol. or with which it is miscible. Among examples, 30 parts of 90% HCOOH is mixed with 100 of bleached cotton linters and heated in a closed container at 65° for 18 hrs.

Mixed organic acid esters of cellulose. Carl J. Malm (to Eastman Kodak Co.). U. S. 2,173,945, Sept. 26. A process for prepg. a mixed ester of cellulose contg. acetyl and acid groups of 3–4 C atoms comprises presoaking cellulose with HOAc, adding acid of 3–4 C atoms, cooling the mass to a temp. of not more than 15° but not to a point where solidification of the liquid occurs, adding an anhydride-free soln. of H_2SO_4 in an acid of 3–4 C atoms and maintaining the mass at a temp. of 5–15° for a short time; subsequently adding an impelling anhydride and esterifying the cellulose, the bath contg. at least 20% of propionyl or butyryl based on the total acyl content of the bath.

Cellulose esters. British Celanese Ltd. Brit. 507,126, June 9, 1939. Cellulose acetates and other org. esters of cellulose are stabilized by being subjected, after ripening, to a treatment with a tertiary amine in which at least 2 aryl or aralkyl radicals are attached to a tertiary N atom, e. g., diphenylaniline, dibenzylaniline, benzylethylaniline, benzylphenylaniline. During the ripening process, small quantities of inorg. salts, e. g., $AlCl_3$, $ZnCl_2$ or HCl may be added since these assist in reducing the formation of unstable compds. The catalyst used for esterification may be wholly or partly neutralized before addn. of the amine. Cellulose esters that are to be treated after pptn. may during pptn. be treated with hypochlorite, etc., to improve their color.

Degraded celluloses. Leon Lilienfeld. Brit. 507,138, June 7, 1939. Textile materials are finished by applying to them a soln., colloidal suspension, paste or magma of at least 1 degradation product of cellulose in a liquid medium capable of dissolving at least a portion of such product, the product being of such a nature that its solns., dispersions, pastes or magmas in NaOH are incapable of yielding coherent films. The materials are thereafter treated with a pptg. or coagulating agent, e. g., an agent capable of coagulating viscose, or H_2O or a soln. of alkali carbonate. The degradation product may be prepd. by treating cellulose with at least 1 degrading, hydrolyzing or oxidizing agent. Before being degraded, the cellulose may be treated with a mercerizing agent. The degradation product may be applied in conjunction with filling or softening agents, or with an alkali-sol. cellulose deriv., e. g., viscose. Among examples, wood pulp is treated with HCl of 0.5% concn. at 100° for 6–12 hrs., the product is treated with NaOH of 9% concn., applied to a fabric and coagulated in a bath used in the viscose art, e. g., a Müller bath.

Washing bands or films. Ernest Bleibler. Brit. 508,408, June 30, 1939. Washing vats for bands in continuous manuf., particularly for films of cellulose hydrate, are divided into compartments contg. 1 or more runs of the film, and the liquid is taken from the lowest point of 1 compartment and carried to the top or near the surface of the preceding compartment. Each compartment slopes toward the point where the liquid leaves it, and the liquid travels by gravity in countercurrent to the direction of travel of the band. One or more slots are provided between the vats and the outer metal frames for overflowing liquid.

Bleaching cellulose fibers. Buffalo Electro-Chemical Co., Inc. Brit. 507,664, June 16, 1939. Bleaching of cellulosic fibers, natural or artificial, including paper pulp, is effected by satg. them with a soln. contg., per l., at least 20 cc. of H_2O_2, 30% by vol., or equiv. amts. of per compds. normally generating H_2O_2 in soln., and an alkali content equiv. to at least 5 g. NaOH, the soln. being maintained at room temp., i. e., up to 125°F., and the goods being permitted to bleach without any substantial evapn. of the soln. Specified alkalies are Na silicate, $Na_4P_2O_7$, Na_2HPO_4, Na_3PO_4, $NaHCO_3$ and borax, and to the bath so obtained may be added other substances, including other alkalies, e. g., NaOH, Na_2CO_3, NH_3, org. bases, and soaps, sulfonated oils, solvents or wetting-out agents. Cf. *C. A.* **32**, 2764[4].

Viscose. Vereinigte Glanzstoff-Fabriken A.-G. Brit. 508,172, June 27, 1939. Viscose of low hemicellulose (I) content is obtained from ground, preliminarily ripened or unripened alkali cellulose (II). The tufts of II, of low I content if any, are moistened or worked up to a dough with not exceeding 3 times their wt. of 8–12% NaOH. After standing 1 or more hrs., the alkali together with dissolved I is pressed out and the II is loosened again. It is then treated with a mercerizing lye of 18% or more of NaOH, excess alkali being pressed off, and the material is again loosened. The II is then xanthated and dissolved in alkali to form viscose, which may be extruded into an acid spinning bath and the filaments obtained may be subjected to a high degree of stretching.

Viscose artificial threads. Alsa Soc. anon. Brit. 508,285, June 28, 1939. Threads having hollow filaments are produced from a viscose contg. Na_2CO_3, any tendency for the formation of an insol. double carbonate of Na and Ca being removed by incorporation in the viscose, prior to filtration, of substances for pptg. the traces of Ca introduced, e. g., by the wood pulp. Pptn. of the Ca may be effected by means of oxalates, secondary orthophosphates, metaphosphates, borates, hyposulfites, aluminates and their mixts. with silicates, or by means of soaps. Instead of soap, glycerides or other esters of higher fatty acids, or the acids themselves, may be used. In an example, stearic acid is incorporated in a viscose contg. Na_2CO_3, any Ca stearate formed being removed during the subsequent filtration.

Artificial filaments, etc. I. G. Farbenindustrie A.-G. Brit. 508,049, June 26, 1939. Filaments, bands, films, foils, etc., are made by spinning into a pptg. liquid a crude soln. of a primary cellulose acetate, which soln. has been hydrolyzed so that the actual AcOH content of the cellulose acetate is diminished but remains above 59%. In an example, cellulose is acetylated in a bath contg. Ac_2O, methylene chloride and H_2SO_4 and hydrolyzed by addn. of 50% AcOH in slight excess over that required to destroy the residual anhydride. The hydrolysis is continued until the cellulose acetate contains 60–61% of AcOH, after which the soln. is neutralized and spun into a pptg. liquid.

Apparatus (with a funnel and revolving spinning can) for production of twisted artificial threads. Giovanni Campolunghi. U. S. 2,173,621, Sept. 19. Various structural and operative details.

Rayon. Albert Wagner, Erich Thiess and Thüringische Zellwolle A.-G. Ger. 677,429, June 26, 1939 (Cl. 29*a*. 6.02). Addn. to 668,695 (*C. A.* **33**, 5186[3]). A process for stretch-spinning Cu silk is described.

Rayon, films, etc. I. G. Farbenindustrie A.-G. Brit. 506,803, June 2, 1939. Pigmented artificial fibers, etc., are made by incorporating in an aq. spinning soln. or in the solvent or other liquid miscible with the spinning soln. a pulverulent or coarse-grained prepn. made from a kneadable mass produced by intensive mech. working of the pigment with a H_2O-sol. carrier in a kneading machine, e. g., rollers. Among examples, the prepn. is made from (1) TiO_2 70 and the Na salt of a condensation product of β-naphthalenesulfonic acid with CH_2O 30 parts, and (2) TiO_2 40, sulfite cellulose waste liquor 40, Na_2SO_4 20 parts and H_2O.

Liquid treatment of rayon. Geo. M. Allen, Henry J. McDermott and John W. Pedlow (to American Viscose Corp.). Brit. 508,340, June 29, 1939. Rayon in the form of cakes or hanks is supported for liquid treatment on hollow tubes with a substantially flat longitudinally extending surface, through perforations in which the treating liquid is forced under pressure. The tubes may be intermittently rotated and the direction of rotation from time to time may be reversed to ensure even treatment.

Recovering copper. British Bemberg Ltd. Brit. 508,142, June 27, 1939. Lime-contg. Cu mud obtained in working up Cu-contg. waste waters from the cuprammonium rayon industry, e. g., by pptn. of ammoniacal Cu-contg. spinning H_2O with lime, is treated with NH_3 and

an alkali metal or $(NH_4)_2CO_3$ and preferably with NH_4 salts such as $(NH_4)_2SO_4$ or NH_4Cl so that the Cu is converted into a tetramine compd. and $CaCO_3$ pptd., the $CaCO_3$ carrying down impurities. The soln. is heated (1) at, e. g., 80–85° until all the NH_3 has escaped, the Cu sepg. as a basic salt, e. g., carbonate or sulfate, or (2) with addn. of NaOH, the Cu depositing as CuO, which may be worked up to any basic salt. The NH_3 is led back to the circuit in process (2), partly after conversion into the desired NH_4 salt. In process (1) $(NH_4)_2SO_4$ soln. contg. a relatively small amt. of Cu, sepd. from the basic salt is also introduced into the circulating process. The mud may be previously treated with a deficiency of acid to form a basic salt. 1

Wood pulp. Kübler & Niethammer and Chemische Fabrik Coswig-Anhalt Hans Schraube (Kurt Schwabe, inventor). Ger. 678,230, July 11, 1939 (Cl. 55*a*. 1.40). Addn. to 677,504 (*C. A.* **33**, 9643[5]). The method of 677,504 for making pulp from resinous wood by adding $Ba(OH)_2$ during the pulping is modified by replacing the $Ba(OH)_2$ by other sol. Ba compds. such as the chloride or nitrate. 2

Wood pulp for chemical use. Raphael L. Stern (to Hercules Powder Co.). Brit. 507,040, June 8, 1939. Addn. to 463,437 (*C. A.* **31**, 6006[6]). Cellulose is obtained in a form suitable for chem. treatment by chipping, according to the method of 463,437, felted wood pulp sheets contg. less than 8% moisture. In examples, wood pulp chips so obtained are converted to nitrocellulose and cellulose acetate. 3

Paper pulp. Ernest T. McGregor. Brit. 507,791, June 21, 1939. For producing de-inked paper stock from printed paper, the latter, after soaking in H_2O, is agitated with a soln. of Na_3PO_4 at or below atm. temp. After agitation, it is convenient to add such a quantity of H_2O as will cause the oil, C, etc., to float to the surface, whereupon these impurities are drained off. After the sepn., the pulp is washed, pressed, etc., and the soln. is filtered, strengthened and returned for reuse. 4

Sizing paper pulp. Pattilloch Processes, Inc. Brit. 509,002, July 10, 1939. This corresponds to U. S. 2,147,213 (*C. A.* **33**, 4035[7]).

Paper from groundwood pulp. Rexford W. Hovey (to Oxford Paper Co.). U. S. 2,173,167, Sept. 19. Paper is made from a furnish contg. groundwood pulp as part of the fibrous constituents and alk. carbonate filler, the major portion of the balance of the fibrous constituents of the furnish consisting of at least one pulp of sulfite pulp and soda pulp, the groundwood being present in the paper to the extent of at least 20% of the fibrous constituents of the paper and the alk. carbonate filler being present in the paper in excess of 10% of the wt. of the paper, the brightness of the paper being enhanced by the presence of the alk. carbonate filler, which may be $CaCO_3$. 5

Felt conditioner for papermaking apparatus. Frederick W. Vickery. U. S. 2,173,317, Sept. 19. Various structural and operative details. 6

Suction rolls of papermaking machines. Wm. H. Millspaugh. Brit. 508,964, July 7, 1939.

Automatic electric control systems for regulating the temperature of furnaces, etc., or the moisture content of paper, etc., during manufacture. Siemens & Halske A.-G. Brit. 444,673, Mar. 25, 1936, and 508,266, June 28, 1939, addn. to 444,673.

Clarifying waste water. Fritz Arledter and Hanns Arledter. Ger. 679,906, Aug. 18, 1939 (Cl. 55*d*. 13.01). App. for mechanically clarifying waste water contg. fibers and filling materials from papermaking plant is described. 7

Paper. Wellington G. Reynolds (to Reynolds Mfg. Co.). U. S. 2,174,095, Sept. 26. A sheet of writing paper having a highly calendered but nonglare surface is formed from paper stock consisting of a mixt. of approx. 20% soda pulp and 60% bleached sulfite and about 20% unbleached sulfite and contg. about ¾ of an oz. of American Blue, Index No. 1288, and about 6¾ oz. of Paper Yellow C. H., Index No. 365, to every 1700 lb. of the stock. 8

Safety paper. Francis L. Simons (to George La Monte & Son). U. S. 2,172,856, Sept. 12. A safety paper has incorporated in it an alkali metal bromide and diphenyl thiourea or other substituted thiourea contg. an aromatic or heterocyclic substituent. 9

Unified paper. Richard G. Drew (to Minnesota Mining & Mfg. Co.). U. S. 2,173,829, Sept. 26. A method for the provision of a unified paper highly resistant to splitting or lamination which comprises impregnating a porous web of paper of the character which is normally bibulous and approaching blotting paper in texture with a proteinous soln. of water contg. a plasticizing agent to the point where impregnation is regulated to contain 24 to 27 parts of the soln. to 15 parts of the paper, the soln. contg. approx. 1 part glue, 1.75 to 4 parts plasticizing agent, 3.5 to 6 parts of water, drying the web to the point where it approx. retains from 48 to 40 parts of impregnant to 52 to 60 parts of paper, with the plasticizing agent from 1.7 to 3 times the quantity of the proteinous agent. Glycerol may be used as the plasticizing agent. 10

Containers for oils, of cellulosic materials such as paper. Everett C. Hughes (to Standard Oil Co. of Ohio). U. S. 2,173,517, Sept. 19. A container of material such as paper is provided with an inner coating which may contain Na silicate 80–95, glycero 2.5–15, gum arabic 1–4 and an alkali metal soap such as K oleate about 0.2% or less. 11

Stiff vegetable-fiber board. Geo. H. Ellis (to Insulite Co.). U. S. 2,173,391, Sept. 19. A stiff, homogeneous, board-like product is produced by a process involving simultaneously applying heat and pressure to a moist vegetable-fiber board, the initial temp. being above 315° and progressively decreasing as the moisture content decreases and the pressure increasing progressively as the moisture content decreases. App. is described. Cf. *C. A.* **33**, 7568[7]. 12

24—EXPLOSIVES AND EXPLOSIONS

C. G. 1

Method of measuring velocity of propagation of deflagration. Raymond Zouckermann and Leon Heyberger. *Compt. rend.* **209**, 680–2(1939).—The method is applicable to cases where there is no flame capable of affecting the eye or a photographic film. The essential points are that the gaseous mixt. is contained in a tube of glass or Fe at least 2 m. long and 2–5 cm. diam., along which bolometers consisting of fine (0.04 mm. diam.) Ni wire are distributed. These are mounted in series in one branch of a Wheatstone bridge one diagonal of which is connected with a source of a. c., and the other with a registering oscillograph. With this arrangement moist mixts. of O_2 and H_2 contg. amts. of H_2 near the limit for which propagation of deflagration is possible were examd., showing that the min. proportion of H_2 for such propagation is independent of the diam. of the tube, and that the velocity of propagation increases with the proportion of H_2 and the diam. of the tube. C. A. Silberrad

Removal of nitrous fumes from mine air. H. C. Dod. *Chem. Eng. Mining Rev.* **31**, 494–5(1939).—"Bullets" of chemical used with the explosive liberate NH_3 which removed NO_2 by the formation of the nitrate and NH_4NO_3. W. H. Boynton

The use of firedamp detectors in coal mines. K. Nehring. *Glückauf* **75**, 259–62(1939).—A review of the practice and methods for testing for fire damp shows that the flame safety lamp is the most reliable and is in general use. L. P. Rockenbach

Explosibility of gases from (coal) mine fires. R. Kattwinkel. *Glückauf* **75**, 302–5(1939).—A study of the ignition data for CH_4-CO_2-air and CH_4-N_2-air shows that for air contg. 7% CH_4 the addn. of 17.5% CO_2 or 29.0% N_2 is required to inhibit ignition. Air contg. 8% CH_4 requires 19% CO_2 or 23.5% N_2. The greater inhibiting power of the CO_2 is attributed to its larger heat capacity. At least 15% O_2 is necessary for ignition to take place. L. P. Rockenbach

Masses contg. absorbents for the liquid constituents [for absorbing nitroglycerin in the manuf. of explosives] (Brit. pat. 506,929) **13.**

Electric blasting cap. Lawton A. Burrows (to E. I. du Pont de Nemours & Co.). U. S. 2,173,270, Sept. 19. An elec. blasting cap of the bridge-plug-bead type comprises a charged metal shell, a firing circuit, and an ignition compn. comprising a double salt of lead hypophosphite with lead nitrate, the bridge wire of the firing circuit being embodied in a bead of the ignition compn., the firing circuit being provided with a discharging means in that each leg wire of the firing circuit is bent away from the shell wall at a point between the place of emergence of the wire from the plug material and the locus of the ignition bead, permitting the harmless discharge of static electricity to the shell wall at a point outside the locus of the ignition bead. U. S. 2,173,271 relates to an ignition compn. which comprises Ca hypophosphite and an oxidizing agent such as $KClO_3$ or KNO_3.

Fire extinguishers. Joseph M. F. Bouillon (known as Yves Bouillon). Brit. 508,222, June 28, 1939.

Fireworks. Alberto Cimorosi. U. S. 2,174,202, Sept. 26. A device which forms a jet of flame, such as a skyrocket, comprises a compressed pellet of pyrotechnic material and a coating including Na silicate, whiting and charcoal.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

Azo dyes and their intermediates. XXI. Substantivity of several azo dyes with J acid as coupling component. Paul Ruggli and Oskar Leupin. *Helv. Chim. Acta* **22**, 1170–7(1939); cf. *C. A.* **32**, 7902⁸. The substantivity of dyes in which J acid and its derivs. serve as coupling components and $PhNH_2$ serves as the diazo component are compared. Five monoazo and 2 disazo dyes were prepd. and studied. The diazo soln. was prepd. in the usual way from 4.65 g. (0.05 mol) freshly distd. $PhNH_2$ and then added dropwise at 0–5° with stirring to a similarly cooled alk. coupling soln., followed by further stirring for 4 hrs. in the cold and for 1–8 hrs. at room temp. and then estg. the purity by titration with $TiCl_3$. The following dyes were prepd.: *A* ($PhNH_2$ → J acid), obtained in 18-g. yield (crude) from a coupling soln. contg. 13.1 g. 91% J acid (0.05 mol), 100 cc. H_2O and 25 g. Na_2CO_3, recrystd. from 72 cc. hot H_2O, 100% pure, orange crystals, dyes cotton orange; *B* ($PhNH_2$ → Ph-J acid), obtained in 23-g. yield (crude) from 20 g. 79.5% Ph-J acid (0.05 mol), 100 cc. H_2O and 25 g. Na_2CO_3, recrystd. from 150 cc. 50% alc., 99.5% pure, dark-violet needles, dyes cotton turbid-red; *C* ($PhNH_2$ → Bz-J acid), obtained in 23-g. yield from 22.2 g. 77.4% Bz-J acid (0.05 mol), 100 cc. H_2O and 25 g. Na_2CO_3, recrystd. from 150 cc. 50% alc., 102% pure (high value due to dye being difficult to reduce), red powder, dyes cotton red-orange; *D* ($PhNH_2$ → *m*-$H_2NC_6H_4CO$-J acid), obtained in 25-g. yield from 19.3 g. 93% *m*-$H_2NC_6H_4CO$-J acid (0.05 mol), 100 cc. H_2O and 25 g. Na_2CO_3, recrystd. from 250 cc. 50% alc., 100% pure, orange-red flakes, dyes cotton bright orange; *E* (1 mol $PhNH_2$ → J acid-imine), obtained in 23-g. yield from 26.5 g. 87% J acid-imine (0.05 mol), 100 cc. H_2O, 30 g. crystd. AcONa and 15 cc. 10% AcOH, recrystd. by dissolving in 80 cc. hot H_2O and adding 200 cc. hot alc., 103% pure (difficult to reduce), violet powder, dyes cotton bluish red; *F* (2 mol $PhNH_2$ → J acid-imine), obtained in 10-g. yield from 13.3 g. 87% J acid-imine (0.025 mol), 50 cc. H_2O and 25 g. Na_2CO_3, recrystd. by dissolving in 40 cc. hot H_2O and adding 100 cc. hot alc., 94.5% pure, brown-red powder, dyes cotton bluish red; *G* (2 mol $PhNH_2$ → J acid urea), obtained in 11-g. yield from 17.2 g. 73.9% J acid urea (0.025 mol), 50 cc. H_2O and 25 g. Na_2CO_3, recrystd. from 100 cc. 60% dioxane, 90% pure, brown-red powder, dyes cotton red-orange. Since an accurate detn. of soly. according to previous practice (cf. *C. A.* **25**, 2294) is subject to several sources of error, only the results obtained during the purification were used for basis of comparison. The dye *A* appeared to be the most readily sol. in H_2O. *E* and *F* show approx. the same soly. and are easily sol. in H_2O, but difficultly sol. in 75% alc. *B* and *C* are difficultly sol. in H_2O, while the most difficult is *D*. The diffusion velocities of the various dyes in 2% gelatin were detd. after 24, 48 and 72 hrs. and from the tabulated results it appears the distance of diffusion is the greatest in the case of *A* with practically a progressively decreasing order from *A* to *G*. The individual values for substantivity were detd. by use of the equation: adsorption − desorption = substantivity. In a previous study (cf. *C. A.* **25**, 2295) the first 2 values were detd. by titanometric estn. of the residual dye liquor and colorimetric estn. (resp.) of the extd. soln. after a hot H_2O treatment of the dyed and cold-rinsed skein of cotton, thus giving a range of values from 0 to 100 for the substantivity of a given dye. Since in this case the dyes had poor to moderate substantivity, it appeared more practical to det. colorimetrically the desorption and substantivity directly and then calc. the adsorption. Results, obtained with and without 20% Na_2SO_4 and which are tabulated, confirm the often repeated observation that substantivity and diffusion oppose one another. On the basis of the substantivity measurements given, the monoazo dyes with J acid as the coupling component are not regarded as being substantive since most of them are below a threshold value of 15 in 20% Na_2SO_4. The dye *E* has a value of 19 while *G*, regarded as having "ordinary" substantivity, has a value of 27 compared with 56 of Congo red. The opinion is expressed that the often emphasized "substantive" property of J acid is generally not as valid as assumed but that certain substituents as well as the diazo components, or rather the entire combination of components, are of great importance. John F. Lontz

Azoic dyes. J. A. Wallwork. *J. Soc. Dyers Colourists* **55**, 477–80(1939). A summary. "Solunaphthols" are a series of products all members of which can be used for cotton and, with one exception, for wool and union fabrics. They are not Na salts but are fine powders which actually produce the sol. naphtholates in presence of boiling water only. They enable the Naphthol soln. to be very easily prepd. Compared with the ordinary Naphthols, the Solunaphthol solns. have better wetting and penetrating power, are more resistant to hard water and give solns. of fixed alkali contents. A general procedure is outlined. Azoic colors were best applied to cellulose acetate rayon by: (1) low alky. of the impregnating soln. or suspension and (2) a high temp. during impregnation—conditions exactly the reverse of those generally used for dyeing cotton and other cellulose fiber. It is apparently necessary to apply the Naphthol to cellulose acetate rayon as the Na salt, but without excess alkali and not as the free aryl amides, to obtain max. color strength. Two procedures are outlined. Eight references. W. H. B.

Application of vat dyes and viscose rayon. I. Introduction. J. Boulton and T. H. Morton. *J. Soc. Dyers Colourists* **55**, 481–2(1939).—A study involving the measuring of the rates of exhaustion and the relative rates of diffusion of the dyes into the interior of viscose rayon.

The results show that, even though the main body of vat dyes may exhaust at approx. equal rates, some individual vat dyes will produce well-penetrated dyeings with greater ease. **II. Investigation of the kinetics of vat dyeing: development of methods.** *Ibid.* 482–9.—A method of estg. a vat dye by colorimetry of a stable colloidal soln. of the insol. oxidized coloring matter has been developed and applied to the study of the kinetics of absorption of vat dyes by viscose rayon. The absorption-time curves are similar in type to those obtained for the absorption of direct dyes by viscose rayon yarn. The leuco-dye absorption is controlled by a diffusion process. This has been confirmed on the diffusion of the leuco dye in sheet cellulose by a method which yields a relative diffusion const. for all dyes. The development is studied in 2 steps: (*A*) quant. investigation of vat dye absorption and (*B*) relative diffusion rates of vat dyes into viscose. The conception which regards the process of vat dyeing as an absorption or combination of the leuco dye and cellulose, the progress of which is conditioned by the relatively slow diffusion of the dye mols. to the interior of the cellulosic filament is the best at the present time. **III. Diffusion and exhaustion rates for a range of dyes—their importance in practice.** *Ibid.* 489–95.—Measurements of exhaustion rate, degree of exhaustion and diffusion rate have been made on a range of com. vat dyes and the dyes classified according to the results obtained. The data have been correlated with the behavior of the dyes in practice, their behavior being characterized by a dyehouse test for penetrability and levelness. The vat dyeing material has 2 phases: (1) absorption of dye by part of the dyed material, which causes the dye bath to become rapidly and more or less completely exhausted and (2) a process of leveling dependent for its speed upon the ease of diffusion of the dye in viscose rayon. The study includes the effect of dye-bath conditions on exhaustion rate, and the degree of exhaustion and diffusion rate as well as the importance of temp. and other factors in the control of vat dyeing. Any modification tending to lower the extent to which exhaustion takes place in the first few moments of dyeing must lead to improved results by way of level dyeing. The rate at which exhaustion takes place is smaller at lower temps. The success of certain "leveling agents" depends upon the lowering of the capacity of the dye to exhaust, and to this extent, their use involves waste of dye which may be considerable and possibly prohibitive. The padding method gives better penetration since the dye is unreduced and the fine particles are evenly distributed between the threads before dyeing commences. **IV. A classified list of vat dyes.** *Ibid.* 496–7.—The strike test described in (III) is suggested as a dyehouse lab. method for the classification of vat dyes according to their capacity to penetrate and give level dyeings. A classified list is given of 81 common dyes. Twelve references.

W. H. Boynton

The application of naphthol dyes to cotton and other textiles. I. Joseph Lindsay. *Cotton* (Atlanta) **103**, 59–61 (Nov., 1939).—Four important steps are involved in the general procedure for dyeing naphthols: (1) impregnation (naphtholation), intermediate treatment, development and aftertreatment. Each step is outlined. The developers of these naphthol dyes are aromatic amines which are changed by diazotization into sol. diazonium salts and these active diazo salts couple readily with naphthol or phenol bodies to give insol. colored ppts.

W. H. Boynton

The prevention of dull shades due to the presence of iron in the dyebath, when dyeing with chrome dyes. I. Iron in the water supply. C. L. Bird and E. Molloy. *J. Soc. Dyers Colourists* **55**, 560–4 (1939).—Three products were recommended recently for preventing the deleterious effects of Fe in the dyebath: (1) Calgon T consisting of $(NaPO_3)_6$ 80% and $Na_4P_3O_{10}$ 20%; (2) $Na_2H_2P_2O_7$ and (3) Trilon B—a white powder, probably the Na salt of trimethylamine-α,α',α''-tricarboxylic acid together with some Na_2CO_3. 0.4 part of Fe per 1,000,000 parts water will dull the shade of a chrome dye while 1 part per 1,000,000 parts will completely alter the shade of the dyeing. The effect of varying conditions on the efficiency of these compds. has been studied. It has been confirmed that in the metachrome and chrome bath processes the presence of $K_2Cr_2O_7$ or $KCrO_4$ throughout the dyeing process affords good protection against Fe. It is less effective when dyeing on a chrome mordant. W. H. Boynton

Dyeing of staple fibers. A. M. Serebryakov. *Sherstyanoe Delo* **1939**, No. 2–3, 25–9.—Results are given on the dyeing of staple (cuprammonium and viscose) fibers on lab. and large scale with S dyes, indanthrenes and indigosols. S dyes were used satisfactorily on lab. scale. Most indigosols gave good results while indanthrenes differed. In all cases the cuprammonium fibers were more intensely colored than the viscose. Stability against light was good. Dyeing with 0–11% S dyes in an Obermeyer app. had very little effect upon the strength of the fibers, giving a small elongation. B. Z. Kamich

The dyeing of jute. D. Carter. *Textile Recorder* **57**, 43, 45–6 (Oct., 1939).—The demand for a higher standard of fastness, particularly to light, has necessitated the use of faster and more expensive dyestuffs for furnishing fabrics. Methods of dyeing jute are outlined, also types of dyes used. W. H. Boynton

Sleaziness and the pH control of the knitting dyehouse. Milton J. Hoffman. *Cotton* (Atlanta) **103**, 170, 172 (Oct., 1939).—The origin and correction of sleaziness are discussed. The one-bath method of dyeing and degumming is preferable to the 2-bath and the split-bath methods. The operation of the pH control system is performed as follows: The pH of the water to be used in dyeing and finishing is detd. The dyeing soln. is checked at 10.2. After 30 min. of degumming, the gum removed, being acid in character, reduced the pH to 9.6, at which point the hose are thoroughly degummed. Sufficient buffer salt is added to reduce the pH to 8.5, at which the degumming operation stops, while a very good dyeing condition exists for mercerized yarn and pure silk in combination. W. H. Boynton

Microscopic observations of wool dyeing. H. E. Millson, G. L. Royer and M. E. Wissemann. *Am. Dyestuff Reptr.* **28**, No. 22, *Proc. Am. Assoc. Textile Chem. Colorists* P632 8 (1939).—Results obtained by the use of the microscope and color photography are indicated as regards the blending of wool, fiber selectivity, the effect of strong H_2SO_4 on wool hairs, chrome dyeing, ultraviolet microscopic examns., the effect of moisture on shade, redyeing, dyeing at low temps., mildew and com. dyeing.

W. H. Boynton

Wool-dyeing phenomena. R. H. Kienle and G. L. Royer. *Am. Dyestuff Reptr.* **28**, No. 22, *Proc. Am. Assoc. Textile Chem. Colorists* P638–9 (1939); cf. preceding abstr.—The pertinent details in connection with the set-up for taking colored microscopic moving pictures are given and the assembled app. is illustrated. W. H. Boynton

Significance of temperature in wool dyeing. II. A study of the acid-combining capacity of wool. F. L. Goodall and C. Hobday. *J. Soc. Dyers Colourists* **55**, 529–49 (1939); cf. *C. A.* **32**, 3156⁸.—The effect of temp. on the dyeing properties of the molecularly dispersed Acid Orange GG and the colloidal Polar Yellow Conc. was reinvestigated under more stringent and more comprehensive exptl. conditions than formerly. The effect of temp. on the fundamental acid and acid dye-combining capacities was reviewed and is found to fail in the consideration of possible decompn. of fiber and (or) dye in the course of expt. at high temps. Such decompn. renders the detn. of sorbed acid and dye by these methods unreliable and makes impossible the detn. of wt. of wool present when the exptl. dyeing systems have reached equil. The final fiber wt. can only be detd. by weighing the dyed wool and subtracting therefrom the wt. of dye and colorless acid present and detd. by other means. The colorless acid detn. required a method specific for the anion concerned and a reliable value for combined wt. of wool and dye could then be calcd. These detns. required the sepn. of fiber and dye in a manner to permit either or both of these components to be separately detd. The procedure is outlined for the expts. in 0.01 *N* HCl with Acid Orange GG and Polar Yellow R with varied dyeing conditions and conducted at

maintained for several hrs. with an addn. of NaCl or Na_2SO_4, whereupon the material is rinsed and dried.

Azo dyes. I. G. Farbenindustrie A.-G. Brit. 507,169, June 12, 1939. *o*-Hydroxyazo dyes are made by coupling a Pr or Bu ester of 2-hydroxynaphthalene-6-carboxylic acid (obtainable by esterifying the 2-hydroxynaphthalene-6-carboxylic acid described in Brit. 257,815 (*C. A.* **21**, 3058) with a Pr or Bu alc.) with a diazotized 2-aminobenzene-1-carboxy ic acid contg. a SO_3H group. They dye wool red by the chroming process. In examples, 2-amino-5-sulfobenzoic acid is coupled with the Pr and Bu esters and 2-amino-4-sulfobenzoic acid is coupled with the iso-Bu ester.

Monoazo dyes. Emmet F. Hitch, Swanie S. Rossander and Donovan E. Kvalnes (to E. I. du Pont de Nemours & Co.). U. S. 2,173,052, Sept. 12. From components such as 5-nitro-2-aminoanisol and *N*-methyl-*N*-sorbitylaniline, monoazo compds. are formed in which one member is a radical of the benzene or naphthalene series and the second member is the radical of a tertiary aryl amine in which the aryl nucleus is from the benzene or naphthalene series and the amino N is connected to an alkyl group and a polyhydroxyalkyl group having 4–6 C atoms and one less hydroxy group than carbons, with an azo bridge para to the tertiary amino group connecting the component radicals. Such dyes dye yellow to red shades, etc., and numerous examples are given.

***o*-Hydroxyazo dyes.** Achille Conzetti and Abram Oulevay (to J. R. Geigy A.-G.). U. S. 2,173,410, Sept. 19. From components such as a diazotized *o*-aminophenol and 3-amino-8-sulfo-2-naphthoic acid, water-sol. dyes are obtained which dye wool in an acid bath by the after-chroming method green shades of good fastness to fulling, potting and light. Several examples with details are given.

Anthraquinone acid wool dye. Henry R. Lee (to E. I. du Pont de Nemours & Co.). U. S. 2,172,763, Sept. 12. A blue dye is prepd. by condensing 1-amino-2-methyl-4-bromoanthraquinone with cresidine and then sulfonating for the introduction of one sulfonic acid group into the mol. Various details are given.

Oxazine dyes. I. G. Farbenind. A.-G. (Fritz Hess and Heinz Pardon, inventors). Ger. 679,984, Aug. 19, 1939 (Cl. 22*c*. 4). Water-sol. oxazine dyes are prepd. by heating substitution products of 2,4,6-trinitrobenzene contg. an exchangeable substituent adjacent to an amino group, with *o*-aminophenols which contain solubilizing groups, in the presence of acid-binding agents, till the oxazine ring is closed. Thus, the HCl salt of 3-amino-2-hydroxybenzoic acid is dissolved in water and heated with crystd. AcONa and picryl chloride in the presence of soda to give a dye. Other examples and the structural formulas of the dyes produced are given.

Sulfur dyes. I. G. Farbenind. A.-G. Ger. 679,985, Aug. 18, 1939 (Cl. 22*d*. 1). 4-Hydroxydiarylamines are sulfurized first with Na_2S and S, or with S alone, in optional presence of a catalyst at a high temp., to form a thiazine compd., and by heating the thiazine compd. in an aliphatic or cyclic alc. with fused S, and Na_2S, and optionally an oxidizing agent, to give sulfur dyes. Thus, 4′-hydroxyphenyl-2-aminonaphthalene is heated with S and Na_2S. The product is dissolved in BuOH and treated with S and Na_2S to give a dye coloring cotton in a Na_2S bath in black shades. Other examples are given.

Thioindigo dyes. John E. Cole (to E. I. du Pont de Nemours & Co.). U. S. 2,173,506, Sept. 19. A thioindigo of high tinctorial value is produced by oxidizing a thioindoxyl compd. such as 4-methyl-6-chlorothionaphthene in the presence of an isopropylnaphthalene alkali sulfonate. Several examples are given.

Brown vat dyes. I. G. Farbenindustrie A.-G. Brit. 506,761, June 5, 1939. Dyes that are quinones of the carbazole series are obtained by causing 1,4- or 1,2-naphthoquinones that are unsubstituted in the quinonoid nucleus or 1,2-naphthoquinones having in 4-position a SO_3H radical and being unsubstituted in 3-position to react at elevated temp. with such 1,2,3-triazoles as are derived from aromatic *o*-diamines, N being split off. An oxidizing agent may be present in the reaction mixt. Among examples, (1) β-naphthoquinone is caused to react in $PhNO_2$ or glacial AcOH with 1,2,3-benzotriazole in the presence of PbO_2, or in $PhNO_2$ with the azimido compds. derived from 1,2-naphthylenediamine, 4-chloro-1,2-phenylenediamine, 1,2-diamino-5-benzoylaminoanthraquinone, 4-nitro-1,2-phenylenediamine, 3,4-diaminobiphenyl, 3,3′-diaminobenzidine, 1,2-diamino-4,6-dichlorobenzene and 4-chloro-1,2-naphthylenediamine, and (2) K β-naphthoquinone-4-sulfonate is caused to react with 1,2,3-benzotriazole in cyclohexanol in presence of KOAc.

Color lakes. Alfred Siegel (to E. I. du Pont de Nemours & Co.). U. S. 2,173,699, Sept. 19. Color lakes consisting principally of a water-insol. phthalocyanine coloring material such as Cu phthalocyanine pigment and a metallic resinate such as Ba resinate have relatively easy grinding qualities and *produce printing inks* of greater length, lower consistency and better flow than those prepd. from the same toner without the resinate. Numerous examples with details are given.

Hydroxybiphenylene oxide. I. G. Farbenind. A.-G. (Karl Zahn and Kurt Schimmelschmidt, inventors). Ger. 679,976, Aug. 19, 1939 (Cl. 12*q*. 24). 3-Hydroxybiphenylene oxide and its substitution products are prepd. by treating 2′-halo-2,5-dihydroxybiphenyl with an alkali. Thus, 2′-chloro-2,5-dihydroxybiphenyl is treated with fused KOH to give 3-hydroxybiphenylene oxide. The prepn. of 7-methyl-, 7-chloro-7-methoxy-, 6-chloro-, 6-methyl-3-hydroxybiphenyl, and 3,6-, 3,5- and 3,8-dihydroxybiphenyl is also described. The compds. are used as *dye intermediates*.

Sulfones. I. G. Farbenindustrie A.-G. Brit. 507,378, June 14, 1939. Divided on 490,043 (*C. A.* **33**, 6142). *m*-Halogenated *o*- and *p*-amino sulfones are prepd. by the action of NH_3 or an agent that sets free NH_3 on polyhaloaryl sulfones of formula *m*-halo-*o*(or *p*-)-haloaryl-SO_2R, where R is an alkyl, aralkyl or aryl residue and further substituents, e. g., alkyl, hydroxyalkyl and aryl groups, further halogen atoms but no NO_2 groups may be present. In the examples, 3-chloro-4-aminophenyl methyl sulfone, 3-chloro-4-aminophenyl ethyl sulfone, 2-amino-5-chlorophenyl ethyl sulfone and 3-chloro-4-aminodiphenyl sulfone are obtained, resp., from 3,1-dichlorophenyl methyl sulfone, 3,1-dichlorophenyl ethyl sulfone, 2,5-dichlorophenyl ethyl sulfone and 3,4-dichlorodiphenyl sulfone. The products are *useful as intermediates for the manuf. of azo dyes* and *pharmaceutical products*.

Dyeing cellulose textiles. Courtaulds Ltd. and Ernest E. Tallis. Brit. 506,793, May 30, 1939. The dyeing properties of textile materials comprising cellulose or its derivs. that do not contain protein substances or their derivs. or basic amino or imino groups, e. g., cotton, rayon and linen, are improved by incorporation therein of a product obtained by causing $CNNH_2$ and CH_2O to react under acid or neutral conditions. Alternatively, the materials are impregnated with a soln. obtained by the admixt. of solns. of $CNNH_2$ and CH_2O, maintained slightly acid, and are subsequently dried and heated to cause condensation. Alternatively, the condensation products may be incorporated in the solns. from which artificial threads are produced. Among examples, crude $CaCN_2$ is extd. with H_2O, filtered, neutralized with strong H_2SO_4, the $CaSO_4$ is filtered off and CH_2O soln., NH_4SCN and H_2O added to the filtrate; viscose staple fiber is steeped in this soln., centrifuged, dried and heated for 20 min. at 140°, whereupon it is dyed with Azo-geranine 2GS in a bath contg. H_2SO_4. The process increases the affinity of the material for substantive, S, vat, azoic, basic and acid dyes and for cellulose acetate, dyes, etc. Intensifiers or other compds. known to increase the affinity of the material for certain direct dyes may be added to the treatment solns.; when such compds. are basic, e. g., NEt_3, they are neutralized before being added.

Dyeing acetate rayon. Wm. J. Grubb, Cecil Shaw, Reginald H. Sennett and Imperial Chemical Industries Ltd. Brit. 507,748, June 20, 1939. Acetate rayon is dyed black shades by applying thereto from an aq. bath 1-amino-4-*p*-nitroanilinoanthraquinone-2-sulfonic acid (I) or a sol. salt thereof. Among examples, acetate rayon

yarn is scoured in a very dil. soln. of soap and NH_3, washed in cold H_2O and entered into an aq. bath contg. I, the temp. is then raised to 80°, NaCl is added and the temp. maintained at 80–85° for 45 min., whereupon the yarn is washed and dried to obtain a greenish black dyeing.

Dyeing textile materials such as those of cellulose acetate. Robert W. Moncrieff and Albert W. M. Cooke (to Celanese Corp. of America). U. S. 2,173,178, Sept. 19. A process for coloration of textile materials having a basis of an org. deriv. of cellulose with an azo dye by applying a diazotizable amine and an aryl amide of hydroxynaphthoic acid to the materials and forming the azo dye in the materials from such components involves applying the two components to the materials while they are in package form by passing through the package a soln. of the components in an org. solvent medium which comprises 75 to 90% of CCl_4 or petrol and 10 to 25% acetone or EtOAc.

Dyeing, bleaching or other liquid treatments of textile materials, paper stock, hides, leather, etc., in a closed kier. Henry C. Nichols. U. S. 2,174,178, Sept. 26. App. is described, and a method of treating pervious material in a closed kier, wherein the treating fluid is continuously circulated throughout the treatment in a closed path and under pressure through the material, while maintaining a substantially uniform pressure differential at opposite sides of such material throughout the treatment by bypassing a portion of the fluid around the material.

Developing colors on fabrics with use of steam and acid vapors. Albert S. Jones (to Arnold Print Works). U. S. 2,174,227, Sept. 26. Various details of app. and operation.

Vat color printing pastes for use on textiles such as cellulosic materials. Charles F. Miller (to E. I. du Pont de Nemours & Co.). U. S. 2,174,005, Sept. 26. A vat dye such as C. I. No. 1184 or No. 1217 is used with acetaldol, which serves to prevent "scumming" and "livering."

Printing pastes for textile fabrics. Alan A. Claflin. U. S. 2,172,833, Sept. 12. A printing paste for use in fixing color on a fabric by a steaming process contains a dye together with Na lactate for thickening the paste and for preventing the printed design from drying out before its color is fixed by the steaming process.

Locust-bean thickening for use in textile printing preparations. Durand & Huguenin A.-G. Brit. 508,135, June 27, 1939. A thickening in which the proportion of locust-bean flour to H_2O is not greater than 1 :20 is improved by incorporating therein a protein, e. g., egg albumin, glue, or a degraded protein or a substance contg. such. A suitable thickening contains locust-bean flour 20, glue, advantageously degraded by boiling with H_2O, 10, salicylic acid, as preservative, 1 and H_2O 969 parts. Among examples of its use, (1) wool is printed with an aq. paste contg the dye 4-nitroaniline-2-sulfonic acid → (acid) 1,8-aminonaphthol-3,6-disulfonic acid (alk.) ← 3-amino-4-sulfobenzeneazosalicylic acid, PhOH, glycerol, the thickening, $(COONH_4)_2$, urea and Cr lactate and steamed and further treated as usual, and (2) cotton is printed with an aq. paste contg. Indanthrene Brilliant Green 4G, urea, molasses, the thickening, K_2CO_3 and Hydrosulfite NF and steamed and further treated as usual.

Tank and rack suitable for treating fabrics or yarn cops with dye solutions, etc. Adolf Schrey. U. S. 2,174,016, Sept. 26. Various details of an app. having a rack connected to means for effecting its oscillation in the soln. used.

Casein artificial fibers. Giuseppe Donagemma, Piero Donagemma and "Snia-Viscosa" (Società nazionale industria applicazioni viscosa). Brit. 507,114, June 9, 1939. Fibers are produced by spinning a NaOH soln. of casein contg. a borate of Na, e. g., borax, or a phenol, or a homolog of PhOH, or creosote, or a mixt. of any of these substances. The presence of these substances in the spinning soln. renders a sep. treatment of the coagulated casein fibers with a fixing agent, e. g., CH_2O, unnecessary. Viscose, cellulose acetate or cuprammonium cellulose may be incorporated in the casein spinning soln.

Stapled fibers. Paul Nikles and Franz Wiskemann. U. S. 2,173,789, Sept. 19. App. is described, and a method of producing stapled fibers, comprising feeding a strand of spun artificial filaments to be cut in appropriate lengths of staple fiber, directing two fluid jets onto the moving strand, one of the jets being directed rotationally thereby imparting a turning effect to the strand, controlling the turning effect for twisting the individual filaments of the strand in the manner of a twisted rope as tightly as permissible, and cutting the twisted rope into appropriate lengths of staple fiber in timed relation with its feed movement while guided by the jets, the second jet longitudinally surrounding the twisted portion of the rope to steady the portion while being cut.

Viscose staple fibers. Schlesische Zellwolle A.-G. Brit. 507,128, June 9, 1939. Viscose fibers are curled or loosened by treatment with hot dil. solns. of alkali metal carbonates before, during or after stapling. The treatment may be conducted before the spinning acid has been removed from the fibers or when it has been partly removed. A further modification is first to remove completely the spinning acid, then reacidify with a volatile org. acid, e. g., AcOH, and finally treat with the hot carbonate soln.

Treating artificial threads. Courtaulds Ltd., John H. McKeown and Eric A. Morton. Brit. 507,953, June 23, 1939. A continuous tow of artificial threads, filaments, etc., is treated with washing, bleaching and desulfurizing liquids by means of a grid onto which the tow falls and which comprises fixed longitudinal bars and intermeshing bars that have an up-and-down and longitudinal to-and-from movement so that the tow forms a blanket of overlapping small coils.

Apparatus for twisting threads or filaments. Eric A. Morton (to Courtaulds Ltd.). U. S. 2,173,762, Sept. 19. Various structural and operative details.

Liquid treatment of yarns and other textile materials. Wm. B. Brown. Brit. 508,147, June 27, 1939. Air is entrained by a jet of steam as it is injected actually into the liquid in a dye or other liquid treatment bath or in a chamber from which the jet or each jet of a mixt. of steam and air is discharged into the liquor in which yarns or other loose textile materials, piece goods or *leather* is being treated, to cause circulation of the liquor throughout the bath.

Liquid treatment of hanks of yarn. Wm. Oliver and John Marsden. Brit. 507,763, June 20, 1939. Pole marking of hanks during dyeing or other liquid treatment is prevented by intermittently raising the hanks on their supporting poles by means of air or other gas during the treatment and allowing the hanks to sink back onto the poles between these intermittent periods.

Treating sewing thread such as that of cotton. Alfred Burgeni (to Clark Thread Co.). U. S. 2,173,997, Sept. 26. App. is described, and a method of treating sewing thread of native cellulosic fibers which involves thoroughly wetting the thread without substantially changing its chem. compn., then stretching the wet thread beyond its elastic limit and short of its breaking point, releasing the tension on the thread, and drying it in its condition of released tension. This treatment serves to give better and more uniform tensile strength. U. S. 2,173,998 (Alfred Burgeni, Wm. M. Camp and Frederick W. Thomas, joint inventors, to same assignee) describes app. and a method of treating sewing thread of cotton fibers which involves thoroughly wetting the thread with an alk. soln. contg. one or more water-insol. cellulose derivs. such as cellulose methyl, ethyl or glycol ether without substantially changing the chem. compn. of the fibers, then stretching the wet thread beyond its elastic limit and short of its breaking point, and releasing the tension.

Treating textiles. I. G. Farbenindustrie A.-G. Brit. 508,079, June 23, 1939. Textile materials are treated with a product of the reaction of an aliphatic or cycloaliphatic amine contg. a radical having more than 8 C atoms with a compd. obtainable by causing a 1,2-alkylene oxide to react with $CNNH_2$ or a salt thereof. The products are useful as washing agents, preferably in an acid bath, for imparting a full feel to rayon, for enhancing the fastness of dyes, or in any textile treatment that utilizes dispersing agents. In examples, (1) viscose rayon is treated with a

maintained for several hrs. with an addn. of NaCl or Na_2SO_4, whereupon the material is rinsed and dried.

Azo dyes. I. G. Farbenindustrie A.-G. Brit. 507,169, June 12, 1939. *o*-Hydroxyazo dyes are made by coupling a Pr or Bu ester of 2-hydroxynaphthalene-6-carboxylic acid (obtainable by esterifying the 2-hydroxynaphthalene-6-carboxylic acid described in Brit. 257,815 (*C. A.* **21**, 3058) with a Pr or Bu alc.) with a diazotized 2-aminobenzene-1-carboxy ic acid contg. a SO_3H group. They dye wool red by the chroming process. In examples, 2-amino-5-sulfobenzoic acid is coupled with the Pr and Bu esters and 2-amino-4-sulfobenzoic acid is coupled with the iso-Bu ester.

Monoazo dyes. Emmet F. Hitch, Swanic S. Rossander and Donovan E. Kvalnes (to E. I. du Pont de Nemours & Co.). U. S. 2,173,052, Sept. 12. From components such as 5-nitro-2-aminoanisol and *N*-methyl-*N*-sorbitylaniline, monoazo compds. are formed in which one member is a radical of the benzene or naphthalene series and the second member is the radical of a tertiary aryl amine in which the aryl nucleus is from the benzene or naphthalene series and the amino N is connected to an alkyl group and a polyhydroxyalkyl group having 4–6 C atoms and one less hydroxy group than carbons, with an azo bridge para to the tertiary amino group connecting the component radicals. Such dyes dye yellow to red shades, etc., and numerous examples are given.

***o*-Hydroxyazo dyes.** Achille Conzetti and Abram Oulevay (to J. R. Geigy A.-G.). U. S. 2,173,410, Sept. 19. From components such as a diazotized *o*-aminophenol and 3-amino-8-sulfo-2-naphthoic acid, water-sol. dyes are obtained which dye wool in an acid bath by the afterchroming method green shades of good fastness to fulling, potting and light. Several examples with details are given.

Anthraquinone acid wool dye. Henry R. Lee (to E. I. du Pont de Nemours & Co.). U. S. 2,172,763, Sept. 12. A blue dye is prepd. by condensing 1-amino-2-methyl-4-bromoanthraquinone with cresidine and then sulfonating for the introduction of one sulfonic acid group into the mol. Various details are given.

Oxazine dyes. I. G. Farbenind. A.-G. (Fritz Hess and Heinz Pardon, inventors). Ger. 679,984, Aug. 19, 1939 (Cl. 22*c*. 4). Water-sol. oxazine dyes are prepd. by heating substitution products of 2,4,6-trinitrobenzene contg. an exchangeable substituent adjacent to an amino group, with *o*-aminophenols which contain solubilizing groups, in the presence of acid-binding agents, till the oxazine ring is closed. Thus, the HCl salt of 3-amino-2-hydroxybenzoic acid is dissolved in water and heated with crystd. AcONa and picryl chloride in the presence of soda to give a dye. Other examples and the structural formulas of the dyes produced are given.

Sulfur dyes. I. G. Farbenind. A.-G. Ger. 679,985, Aug. 18, 1939 (Cl. 22*d*. 1). 4-Hydroxydiarylamines are sulfurized first with Na_2S and S, or with S alone, in optional presence of a catalyst at a high temp., to form a thiazine compd., and by heating the thiazine compd. in an aliphatic or cyclic alc. with fused S, and Na_2S, and optionally an oxidizing agent, to give sulfur dyes. Thus, 4′-hydroxyphenyl-2-aminonaphthalene is heated with S and Na_2S. The product is dissolved in BuOH and treated with S and Na_2S to give a dye coloring cotton in a Na_2S bath in black shades. Other examples are given.

Thioindigo dyes. John E. Cole (to E. I. du Pont de Nemours & Co.). U. S. 2,173,506, Sept. 19. A thioindigo of high tinctorial value is produced by oxidizing a thioindoxyl compd. such as 4-methyl-6-chlorothionaphthene in the presence of an isopropylnaphthalene alkali sulfonate. Several examples are given.

Brown vat dyes. I. G. Farbenindustrie A.-G. Brit. 506,761, June 5, 1939. Dyes that are quinones of the carbazole series are obtained by causing 1,4- or 1,2-naphthoquinones that are unsubstituted in the quinonoid nucleus or 1,2-naphthoquinones having in 4-position a SO_3H radical and being unsubstituted in 3-position to react at elevated temp. with such 1,2,3-triazoles as are derived from aromatic *o*-diamines, N being split off. An oxidizing agent may be present in the reaction mixt. Among examples, (1) β-naphthoquinone is caused to react in $PhNO_2$ or glacial AcOH with 1,2,3-benzotriazole in the presence of PbO_2, or in $PhNO_2$ with the azimido compds. derived from 1,2-naphthylenediamine, 4-chloro-1,2-phenylenediamine, 1,2-diamino-5-benzoylaminoanthraquinone, 4-nitro-1,2-phenylenediamine, 3,4-diaminobiphenyl, 3,3′-diaminobenzidine, 1,2-diamino-4,6-dichlorobenzene and 4-chloro-1,2-naphthylenediamine, and (2) K β-naphthoquinone-4-sulfonate is caused to react with 1,2,3-benzotriazole in cyclohexanol in presence of KOAc.

Color lakes. Alfred Siegel (to E. I. du Pont de Nemours & Co.). U. S. 2,173,699, Sept. 19. Color lakes consisting principally of a water-insol. phthalocyanine coloring material such as Cu phthalocyanine pigment and a metallic resinate such as Ba resinate have relatively easy grinding qualities and *produce printing inks* of greater length, lower consistency and better flow than those prepd. from the same toner without the resinate. Numerous examples with details are given.

Hydroxybiphenylene oxide. I. G. Farbenind. A.-G. (Karl Zahn and Kurt Schimmelschmidt, inventors). Ger. 679,976, Aug. 19, 1939 (Cl. 12*q*. 24). 3-Hydroxybiphenylene oxide and its substitution products are prepd. by treating 2′-halo-2,5-dihydroxybiphenyl with an alkali. Thus, 2′-chloro-2,5-dihydroxybiphenyl is treated with fused KOH to give 3-hydroxybiphenylene oxide. The prepn. of 7-methyl-, 7-chloro-7-methoxy-, 6-chloro-, 6-methyl-3-hydroxybiphenyl, and 3,6-, 3,5- and 3,8-dihydroxybiphenyl is also described. The compds. are used as *dye intermediates*.

Sulfones. I. G. Farbenindustrie A.-G. Brit. 507,378, June 14, 1939. Divided on 490,043 (*C. A.* **33**, 6442). *m*-Halogenated *o*- and *p*-amino sulfones are prepd. by the action of NH_3 or an agent that sets free NH_3 on polyhaloaryl sulfones of formula *n*-halo-*o*(or *p*-)-haloaryl-SO_2R, where R is an alkyl, aralkyl or aryl residue and further substituents, e. g., alkyl, hydroxyalkyl and aryl groups, further halogen atoms but no NO_2 groups may be present. In the examples, 3-chloro-4-aminophenyl methyl sulfone, 3-chloro-4-aminophenyl ethyl sulfone, 2-amino-5-chlorophenyl ethyl sulfone and 3-chloro-4-aminodiphenyl sulfone are obtained, resp., from 3,4-dichlorophenyl methyl sulfone, 3,4-dichlorophenyl ethyl sulfone, 2,5 dichlorophenyl ethyl sulfone and 3,4-dichlorodiphenyl sulfone. The products are *useful as intermediates for the manuf. of azo dyes* and *pharmaceutical products*.

Dyeing cellulose textiles. Courtaulds Ltd. and Ernest E. Tallis. Brit. 506,793, May 30, 1939. The dyeing properties of textile materials comprising cellulose or its derivs. that do not contain protein substances or their derivs. or basic amino or imino groups, e. g., cotton, rayon and linen, are improved by incorporation therein of a product obtained by causing $CNNH_2$ and CH_2O to react under acid or neutral conditions. Alternatively, the materials are impregnated with a soln. obtained by the admixt. of solns. of $CNNH_2$ and CH_2O, maintained slightly acid, and are subsequently dried and heated to cause condensation. Alternatively, the condensation products may be incorporated in the solns. from which artificial threads are produced. Among examples, crude $CaCN_2$ is extd. with H_2O, filtered, neutralized with strong H_2SO_4, the $CaSO_4$ is filtered off and CH_2O soln., NH_4SCN and H_2O added to the filtrate; viscose staple fiber is steeped in this soln., centrifuged, dried and heated for 20 min. at 140°, whereupon it is dyed with Azo-geranine 2GS in a bath contg. H_2SO_4. The process increases the affinity of the material for substantive, S, vat, azoic, basic and acid dyes and for cellulose acetate, dyes, etc. Intensifiers or other compds. known to increase the affinity of the material for certain direct dyes may be added to the treatment solns.; when such compds. are basic, e. g., NEt_3, they are neutralized before being added.

Dyeing acetate rayon. Wm. J. Grubb, Cecil Shaw, Reginald H. Sennett and Imperial Chemical Industries Ltd. Brit. 507,748, June 20, 1939. Acetate rayon is dyed black shades by applying thereto from an aq. bath 1-amino-4-*p*-nitroanilinoanthraquinone-2-sulfonic acid (I) or a sol. salt thereof. Among examples, acetate rayon

yarn is scoured in a very dil. soln. of soap and NH_3, washed in cold H_2O and entered into an aq. bath contg. I, the temp. is then raised to 80°, NaCl is added and the temp. maintained at 80–85° for 45 min., whereupon the yarn is washed and dried to obtain a greenish black dyeing.

Dyeing textile materials such as those of cellulose acetate. Robert W. Moncrieff and Albert W. M. Cooke (to Celanese Corp. of America). U. S. 2,173,178, Sept. 19. A process for coloration of textile materials having a basis of an org. deriv. of cellulose with an azo dye by applying a diazotizable amine and an aryl amide of hydroxynaphthoic acid to the materials and forming the azo dye in the materials from such components involves applying the two components to the materials while they are in package form by passing through the package a soln. of the components in an org. solvent medium which comprises 75 to 90% of CCl_4 or petrol and 10 to 25% acetone or EtOAc.

Dyeing, bleaching or other liquid treatments of textile materials, paper stock, hides, leather, etc., in a closed kier. Henry C. Nichols. U. S. 2,174,178, Sept. 26. App. is described, and a method of treating pervious material in a closed kier, wherein the treating fluid is continuously circulated throughout the treatment in a closed path and under pressure through the material, while maintaining a substantially uniform pressure differential at opposite sides of such material throughout the treatment by bypassing a portion of the fluid around the material.

Developing colors on fabrics with use of steam and acid vapors. Albert S. Jones (to Arnold Print Works). U. S. 2,174,227, Sept. 26. Various details of app. and operation.

Vat color printing pastes for use on textiles such as cellulosic materials. Charles F. Miller (to E. I. du Pont de Nemours & Co.). U. S. 2,174,005, Sept. 26. A vat dye such as C. I. No. 1184 or No. 1217 is used with acetaldol, which serves to prevent "scumming" and "livering."

Printing pastes for textile fabrics. Alan A. Claflin. U. S. 2,172,833, Sept. 12. A printing paste for use in fixing color on a fabric by a steaming process contains a dye together with Na lactate for thickening the paste and for preventing the printed design from drying out before its color is fixed by the steaming process.

Locust-bean thickening for use in textile printing preparations. Durand & Huguenin A.-G. Brit. 508,135, June 27, 1939. A thickening in which the proportion of locust-bean flour to H_2O is not greater than 1 20 is improved by incorporating therein a protein, e. g., egg albumin, glue, or a degraded protein or a substance contg. such. A suitable thickening contains locust-bean flour 20, glue, advantageously degraded by boiling with H_2O, 10, salicylic acid, as preservative, 1 and H_2O 969 parts. Among examples of its use, (1) wool is printed with an aq. paste contg the dye 4-nitroaniline-2-sulfonic acid → (acid) 1,8-aminonaphthol-3,6-disulfonic acid (alk.) ← 3-amino-4-sulfobenzeneazosalicylic acid, PhOH, glycerol, the thickening, $(COONH_4)_2$, urea and Cr lactate and steamed and further treated as usual, and (2) cotton is printed with an aq. paste contg. Indanthrene Brilliant Green 4G, urea, molasses, the thickening, K_2CO_3 and Hydrosulfite NF and steamed and further treated as usual.

Tank and rack suitable for treating fabrics or yarn cops with dye solutions, etc. Adolf Schrey. U. S. 2,174,016, Sept. 26. Various details of an app. having a rack connected to means for effecting its oscillation in the soln. used.

Casein artificial fibers. Giuseppe Donagemma, Piero Donagemma and "Snia-Viscosa" (Società nazionale industria applicazioni viscosa). Brit. 507,114, June 9, 1939. Fibers are produced by spinning a NaOH soln. of casein contg. a borate of Na, e. g., borax, or a phenol, or a homolog of PhOH, or creosote, or a mixt. of any of these substances. The presence of these substances in the spinning soln. renders a sep. treatment of the coagulated casein fibers with a fixing agent, e. g., CH_2O, unnecessary. Viscose, cellulose acetate or cuprammonium cellulose may be incorporated in the casein spinning soln.

Stapled fibers. Paul Nikles and Franz Wiskemann. U. S. 2,173,789, Sept. 19. App. is described, and a method of producing stapled fibers, comprising feeding a strand of spun artificial filaments to be cut in appropriate lengths of staple fiber, directing two fluid jets onto the moving strand, one of the jets being directed rotationally thereby imparting a turning effect to the strand, controlling the turning effect for twisting the individual filaments of the strand in the manner of a twisted rope as tightly as permissible, and cutting the twisted rope into appropriate lengths of staple fiber in timed relation with its feed movement while guided by the jets, the second jet longitudinally surrounding the twisted portion of the rope to steady the portion while being cut.

Viscose staple fibers. Schlesische Zellwolle A.-G. Brit. 507,128, June 9, 1939. Viscose fibers are curled or loosened by treatment with hot dil. solns. of alkali metal carbonates before, during or after stapling. The treatment may be conducted before the spinning acid has been removed from the fibers or when it has been partly removed. A further modification is first to remove completely the spinning acid, then reacidify with a volatile org. acid, e. g., AcOH, and finally treat with the hot carbonate soln.

Treating artificial threads. Courtaulds Ltd., John H. McKeown and Eric A. Morton. Brit. 507,953, June 23, 1939. A continuous tow of artificial threads, filaments, etc., is treated with washing, bleaching and desulfurizing liquids by means of a grid onto which the tow falls and which comprises fixed longitudinal bars and intermeshing bars that have an up-and-down and longitudinal to-and-from movement so that the tow forms a blanket of overlapping small coils.

Apparatus for twisting threads or filaments. Eric A. Morton (to Courtaulds Ltd.). U. S. 2,173,762, Sept. 19. Various structural and operative details.

Liquid treatment of yarns and other textile materials. Wm. B. Brown. Brit. 508,147, June 27, 1939. Air is entrained by a jet of steam as it is injected actually into the liquid in a dye or other liquid treatment bath or in a chamber from which the jet or each jet of a mixt. of steam and air is discharged into the liquor in which yarns or other loose textile materials, piece goods or *leather* is being treated, to cause circulation of the liquor throughout the bath.

Liquid treatment of hanks of yarn. Wm. Oliver and John Marsden. Brit. 507,763, June 20, 1939. Pole marking of hanks during dyeing or other liquid treatment is prevented by intermittently raising the hanks on their supporting poles by means of air or other gas during the treatment and allowing the hanks to sink back onto the poles between these intermittent periods.

Treating sewing thread such as that of cotton. Alfred Burgeni (to Clark Thread Co.). U. S. 2,173,997, Sept. 26. App. is described, and a method of treating sewing thread of native cellulosic fibers which involves thoroughly wetting the thread without substantially changing its chem. compn., then stretching the wet thread beyond its elastic limit and short of its breaking point, releasing the tension on the thread, and drying it in its condition of released tension. This treatment serves to give better and more uniform tensile strength. U. S. 2,173,998 (Alfred Burgeni, Wm. M. Camp and Frederick W. Thomas, joint inventors, to same assignee) describes app. and a method of treating sewing thread of cotton fibers which involves thoroughly wetting the thread with an alk. soln. contg. one or more water-insol. cellulose derivs. such as cellulose methyl, ethyl or glycol ether without substantially changing the chem. compn. of the fibers, then stretching the wet thread beyond its elastic limit and short of its breaking point, and releasing the tension.

Treating textiles. I. G. Farbenindustrie A.-G. Brit. 508,079, June 23, 1939. Textile materials are treated with a product of the reaction of an aliphatic or cycloaliphatic amine contg. a radical having more than 8 C atoms with a compd. obtainable by causing a 1,2-alkylene oxide to react with $CNNH_2$ or a salt thereof. The products are useful as washing agents, preferably in an acid bath, for imparting a full feel to rayon, for enhancing the fastness of dyes, or in any textile treatment that utilizes dispersing agents. In examples, (1) viscose rayon is treated with a

soln. of the imidazoline deriv. from 2 mols. of stearylamine-HCl and aminochloromethyloxazoline-HCl, washed and dried; a full feel results, and (2) a viscose material dyed with Direct Deep Black EW Extra is treated with a soln. of stearylaminoaminoöxazoline hydrochloride; the dyeing is rendered fast to H_2O.

Treating textiles. Tootal Broadhurst Lee Co. Ltd., Harry Corteen and Frederick Charles Wood. Brit. 506,783, May 30, 1939. Textile materials that have been rendered H_2O-repellent by impregnation with an org. N compd. that can be made from a tertiary N base, CH_2O and a fatty alc., amine, amide or urethan contg. at least 10 C atoms, are treated with a neutral or alk. swelling agent. The handle, strength and wearing properties are thus improved. Suitable swelling agents are NaOH, KOH, cuprammonium hydroxide, quaternary NH_4 bases, sulfonium bases, caustic alkalies, with CS_2 and caustic alkalies with ethylene oxide for cellulosic materials, Me_2CO and H_2O for cellulose acetate materials, and caustic alkalies or NH_4OH for wool and silk materials. The materials may also be subjected to further textile finishing processes, e. g. delustering, rendering crease-resisting, shrinking. Among examples, linen is made H_2O-repellent with octadecyloxymethylpyridinium chloride or *N*-carbomethoxyheptadecylaminomethylpyridinium chloride, wetted and immersed in NaOH soln. The swelling may also be applied to a material that has been made H_2O-repellent and impregnated with resin or a reactive aldehyde.

Ennobling textile materials. Walther Kaase and Ernst Waltmann (to Heberlein Patent Corp.). U. S. 2,172,475, Sept. 12. A textile material such as one of cotton or rayon has applied to it asymmetric stearic acid-acetic acid anhydride or other asymmetric fatty acid anhydride contg. a long acyl radical of at least 10 C atoms and a considerably shorter acyl radical capable of being split off upon heating, followed by heating to effect such splitting and to cause a reaction of the textile material with the remainder of the anhydride.

Desizing textile materials. Josef Müller. U. S. 2,173,040, Sept. 12. A textile material such as a cotton fabric which carries a sizing of a polymeric carbohydrate such as a starch sizing is treated with an aq. soln. of a persulfate such as that of Na or K at a temp. above ordinary room temp. (suitably about 50–100°).

Treating fibrous materials such as cotton, wool, rayon or asbestos with aqueous dispersions such as those of waxes and resins. Howard A. Young (to United States Rubber Products, Inc.). U. S. 2,173,241, Sept. 19. A process for waterproofing, sizing, etc., involves assocg. fibrous material with an aq. dispersion contg. 6–30% of colloidal treating materials such as a wax, causing the fibrous material to entrain therein an amt. of the aq. dispersion which ranges from 40–250% of the wt. of the fibrous material and which is less than that required for "wet satn." of the fibrous material so that the fibrous material holds its entire treating bath, the treating bath being capable of depositing on the fibrous material in which it is held substantially all its colloidally dispersed particles under normally noncoagulative conditions for the dispersion, and maintaining the treating bath in the fibrous material under normally noncoagulative conditions for the dispersion until the desired amt. of the dispersed material has deposited on the fibrous material. U. S. 2,173,242 relates to a similar process in which a latex compn. having a solids concn. of 3–30% is used for treating the fibrous material. U. S. 2,173,243 relates to a process which involves assocg. a bath of an aq. dispersion of colloidal treating material which is at a pH in approx. its isoelec. zone with fibrous material under normally noncoagulative conditions for the dispersion, the dispersion being stable in the absence of fibrous material but capable of depositing substantially all of its dispersed particles of treating material on the fibrous material under normally noncoagulative conditions for the dispersion, and maintaining the fibrous material assocd. with the bath under normally noncoagulative conditions for the dispersion until the desired amt. of treating material has been sorbed on the fibrous material. U. S. 2,173,244 relates to a generally similar process in which a latex compn. is used for sorption of rubber on the fibrous material.

Treating cellulose-derivative fabrics. British Celanese Ltd. Brit. 506,862, June 6, 1939. Fabrics contg. yarns comprising a mixt. of fibers of an org. deriv. of cellulose and animal fibers are treated for about 4–6 min. at 10–13° with an aq. soln. of a thiocyanate of an alkali metal, alk. earth metal or NH_3 that has a d. of 6–10°Bé. in order to modify their handle. The fabrics treated may contain other fibrous materials such as regenerated cellulose filaments and the treatment bath may contain, besides the thiocyanate and H_2O, oily materials such as sulfonated or sulfated fatty alcs., vegetable or mineral oils, wool fat or oil. In examples, fabrics consisting of yarns made of about 70 parts cellulose acetate fibers and about 30 parts wool fibers are treated with NH_4SCN soln.

Pile-surfaced materials. Harry A. Wintermute (to Behr-Manning Corp.). U. S. 2,173,032, Sept. 12. App. is described, and a method which comprises establishing an elec. field of periodically alternating polarity, positioning an adhesive-surfaced foundation material such as cloth or paper in this field and bringing comminuted fibrous material into the field in condition to be deposited so as to produce a pile on the adhesive-surfaced material.

Forming pile surfaces on sheet materials. Archibald F. Meston (to Behr-Manning Corp.). U. S. 2,173,078, Sept. 12. App. is described, and a method which comprises providing an elec. field of intermittently varying strength, positioning an adhesive-surfaced material in the field, and applying fibers for forming a pile surface to the field.

Apparatus for taking samples from cotton in bat form. Geo. E. Gaus and Russell G. McWhirter (to the Secretary of Agriculture of the U. S. A.). U. S. 2,173,071, Sept. 12. Various structural, mech. and operative details.

Artificial wool. Joseph Carlier. Brit. 506,895, June 6, 1939. Artificial wool and artificial fibers of high thermal capacity are prepd. by mixing together at least 2 of the following solns., spinning the mixt. into HCl soln. and insolubilizing the threads obtained, e. g., in glycerol-CH_2O. The solns. are (a) a colloidal soln. of a nonthermally reactive fusible PhOH-CH_2O resin in an aliphatic or aromatic alc., a ketone, AcOEt, AcOBu, AcOAm or tricresyl phosphate, (b) a colloidal soln. of Ca or phospho-Ca alginate in H_2O contg. Na_2CO_3, (c) a colloidal alk. soln. of wool or wool waste and (d) a colloidal alk. soln. of casein.

Compound fabrics. Benjamin Liebowitz. Brit. 508,040, June 26, 1939. A continuous process for uniting layers of fabric comprises superposing 2 layers of fabric with a beam of parallel independent yarns of adhesive agent arranged therebetween, applying to the superposed layers a solvent for the adhesive agent, applying a sustained pressure and finally subjecting to successive pressing and airing stages for evapg. the solvent. The yarns may be of cellulose deriv., may contain or be treated with plasticizer and may be spaced apart by cotton or other nonadhesive yarns. App. is described.

Coated fabrics. Eberhard Andreae and Weberei-Beteiligungs G. m. b. H. Brit. 508,711, July 5, 1939. Textiles are rendered H_2O-proof by being treated with a CH_2O-urea or CH_2O-thiourea resin to render them crease-resistant and then being coated on 1 side with a soln. or dispersion of polyvinyl or polyacrylic resin free from fillers or plasticizers. One or more layers may be applied. Stickiness of the applied layer may be reduced by powdering with talcum and treating with a H_2O-repelling agent, e. g., a soln. or dispersion of wax or wax-like substances, e. g., paraffin, Al soaps, preferably contg. dispersing agents, e. g., soap, albuminoid substances. $(HCOO)_3Al$ or $(AcO)_3Al$ or Zn or Th salts may also be present.

Rubberizing textiles. Dunlop Rubber Co. Ltd., Evelyn W. Madge and Edward A. Murphy. Brit. 507,493, June 15, 1939. When impregnating with rubber materials that are formed wholly or partly of cotton, e. g., duck for belting and tire cord, the adhesion of the rubber is assisted by initially dewaxing the cotton and subsequently applying thereto as an adhesive an aq. dispersion of rubber contg. an addn. of resorcinol resin.

Ornamental woven elastic fabric. John V. Moore (to Moore Fabric Co.). U. S. 2,173,976, Sept. 26. An ornamental elastic fabric suitable for embossing to simulate *leather* is formed of interwoven warps and wefts, the warps comprising rubber warp threads entirely buried below the face of the fabric and addnl. nonelastic binder warp threads, and the wefts consisting of nonelastic yarn having an initial coating of a substance which is relatively hard but not brittle, the coating being applied to the weft yarn before the yarn is woven in the fabric and being capable of receiving and retaining a permanent surface alteration, and the coated wefts wholly overlying and concealing the rubber warp threads in the fabric and being collectively embossed with an ornamental design and being free for transverse movement relative to each other after such embossing.

Treating canvas for belting. Walter H. Tolsey (to Main Belting Co.). U. S. 2,174,022, Sept. 26. A method of producing belting comprises folding and stitching a length of canvas, impregnating the canvas with a mixt. including a drying oil and a mineral jelly, permitting the drying oil to oxidize partially and before the drying oil has completely oxidized filling the canvas with a mixt. including a drying oil, a cereal flour and casein, permitting the drying oil to oxidize partially and before the drying oil has completely oxidized coating the treated canvas with a varnish.

Treating packaged rayon to effect bleaching, etc. Adrian J. L. Moritz, Willem J. D. van Dobbenburgh, Alfred E. Sunderland and Gilbert I. Thurmond (to American Enka Corp.). U. S. 2,172,516, Sept. 12. A method of aftertreating dried twisted rayon threads in package form, the outer convolutions of which have been unable to shrink to the same extent as the inner layers, comprises moistening the outer surfaces only of the package so that the outer layers of thread will acquire from 40% to 100% moisture and thereafter redrying the same.

Bleaching fibrous materials. Martin Evoy. U. S. 2,173,474, Sept. 19. Animal, vegetable or artificial fibrous materials are wetted, at a temp. not substantially above 38°, with a sufficient quantity of an acid, aq. soln. of H_2O_2 to render the material moist, and the material is maintained moist for a period of not less than 2 hrs. and until the bleaching is substantially complete, and is then dried.

Starch solutions for textile sizings, etc. Josef Müller. U. S. 2,173,041, Sept. 12. Starch is heated with water and a persulfate such as that of K (suitably also with an alk. per compd. such as Na percarbonate) until the starch is substantially dissolved, the persulfate being used in such small amount that the acid reaction products produced from its decompn. are substantially neutralized by such basic substances as are commonly present in undistd. water and in the starch used. Several examples are given.

Waterproofing textiles. Courtaulds Ltd. and Edwin H. Sharples. Brit. 508,701, July 5, 1939. Cellulose textile material, e. g., cotton, regenerated cellulose, that has been dried until it is practically free from moisture but which contains a small proportion, e. g., 0.1%, of a fatty substance, is subjected to the action of dry Cl after which an insol. metallic compd. of a fatty acid is formed therein. The fatty substance may be normally present in natural fibers, but in the case of artificial fibers it is added to the soln. from which the threads are made or by aftertreatment. In an example, viscose woven fabric is treated with Na oleate soln., dried at 60° for 6 hrs., placed in an atm. contg. 0.3% Cl for 1 hr. at 60°, removed, immersed in a soap soln., e. g., Na oleate, centrifuged and rinsed in hard H_2O contg. 10–30 parts of Ca or Mg compds. per 100,000 of H_2O.

Waterproofing and creaseproofing textiles. Färberei-A.-G. vo mals E. Stolte Nachfolger & Wm Missy, Ernst Waltmann and Edgar Wolf. Brit. 508,173, June 27, 1939. Divided on and addn. to 494,761 (*C. A.* **33**, 3184[8]). There are used in place of the quaterna y NH_4 compds. of 494,761 quaternary NH_4 compds. of the halomethyl ethers of urethans, hydrazides and partially acylated ureas of formula $ROCONH_2$, $RCONHNH_2$ and $RCONHCONH_2$, where R is an aliphatic residue of at least 10 C atoms, which compds. may be prepd. as described in Brit. 492,699 (*C. A.* **33**, 1961[9]).

Waterproofing wool. Merkel & Kienlin G. m. b. H. Ger. 678,144, July 11, 1939 (Cl. 8*k*. 3). Addn. to 661,-673 (*C. A.* **32**, 8798[9]). The method of 661,673 for waterproofing wool fibers by impregnating them with a Cl-yielding agent is modified by using a waterproofing bath contg. the Cl-yielding agent. Thus, wool yarn is immersed in an impregnating bath consisting of an aq. soln. of $(NH_4)_2SO_4$, $CaCl_2$ and HCl. After rinsing, the wool is treated with a bath of soap and paraffin emulsion.

Rendering textile materials water-repellent. Ernst Waltmann and Edgar Wolf (to Heberlein Patent Corp.). U. S. 2,173,029, Sept. 12. A process for "ennobling" textile materials such as viscose rayon for raincoats comprises impregnating the material with stearic acid isocyanate or other isocyanic acid esters having the formula RCO-N=C=O in which R represents an alkyl, cycloalkyl or aralkyl radical contg. a satd. alkyl radical of at least 10 C atoms or represents a satd. or unsatd. radical of an alc. of the sterol series, followed by heating of the impregnated material (suitably for 5 min. at 140°). Cf. *C. A.* **34**, 2748.

Fire-, water- and mildew-proofing cotton fabrics, etc. Edwin C. Clayton and Lawrence L. Heffner (to Wm. E. Hooper & Sons Co.). U. S. 2,172,698, Sept. 12. See Can. 378,801 (*C. A.* **33**, 2351[1]).

Quaternary ammonium compounds. Max Flores and Wilhelm Essers. Brit. 507,687, June 20, 1939. A compd. of formula $RXNH_2$, where R is an alkyl, aryl, cycloalkyl or aralkyl radical and X is CO or SO_2, is condensed with CH_2O or $(CH_2O)_3$ and the product is treated first with a fatty acid chloride or chlorocarbonic ester contg. an aliphatic radical of at least 10 C atoms and then with a tertiary base. The final products are H_2O-sol. quaternary NH_4 compds. that may be used *for waterproofing textile materials* or *for aftertreating textile materials that have been dyed* with substantive dyes, to increase their resistance to washing. Among examples, *p*-toluenesulfonamide is fused with $(CH_2O)_3$ and the product is treated with stearoyl chloride and then with pyridine.

26—PAINTS, VARNISHES AND LACQUERS

A. H. SABIN AND CARLTON H. ROSE

The manufacture of paint and allied products. A. Brothman and H. Kaplan. *Natl. Paint Bull.* **3**, 18–21 (Oct., 1939).—A tech. discussion from the standpoint of the mixing operation. The conclusions are: that the improvement of mixing equipment lags far behind the other aspects of paint production in tech. advance. W. H. Boynton

Aluminum paint leaf retention. Cornelius S. Fleming and Wm. Mellema. *Am. Paint J.* **24**, Convention Daily, 8 (Nov. 3, 1939).—A 149° oven test and the boiling water-bath test are dependable tests to det. the loss or leafing of Al pastes and powders. The use of smaller amts. of paste than usually required for paints is a dependable accelerated method for testing leafing of Al pastes, powders and vehicles. Exposure of Al paints to the heat of the sun in open or closed cans is a suitable accelerated test for Al paints, the method of exposing open cans being the faster. The boiling water-bath test is a quick simple dependable method for detg. the relative leafing retention of Al paints. W. H. Boynton

The loss of drying power of black paints caused by aging. J. E. Rose and H. A. Bennett. *Am. Paint J.* **24**, Convention Daily, 10–11, 12, 17 (Nov. 2, 1939).—Methods of correcting the loss of drying power were studied and drying rate curves prepd. for treated samples. The theory and

procedure are outlined. Carbon black, bone black, lampblack and graphite pigments were compared. Carbon black causes the greatest losses in drying power of the linseed-oil mixts. with the other pigments following in order of listing. W. H. Boynton

Analysis of paint decomposition due to weathering. Henry A. Ball. *Am. Paint J.* 24, Convention Daily, 12–13, 14–15, 16–17(Nov. 3, 1939).—A study purporting to make a complete analysis of all the products during the breakdown of films of 2 different paints. The exact mechanism of the deterioration can be shown by periodic chem. analysis of the residual film, the chalk and the washed off material. Analytical results are tabulated. W. H. B.

Technique of the painting process in the Bagh caves in the Gwalior State. S. Paramasivan. *Nature* 144, 554–5 (1939); cf. *C. A.* 31, 7266[6]; 32, 6885[9].—Chemical analyses and particle size distributions are given for the earth plaster and lime plaster coats. The pigments were yellow and red ochers, C, lime and gypsum, terreverte and lapis lazuli. The binding medium on the earth plaster was animal glue; the pigments were in lime medium on the lime plaster. G. M. Petty

Loss in drying power in brown paints—Kansas City Paint & Varnish Production Club. *Am. Paint J.* 24, Convention Daily, 17, 18(Oct. 26, 1939).—A study of brown house paints made with Pb, Mn and Co naphthanate driers, and pigments drawn from lampblack, red iron oxide, yellow iron oxide, asbestine, china clay and silica. The oil was neutral linseed, acid no. less than 0.30. All reasonable combinations of these pigments were tried. Iron oxide was the worst offender and only lampblack was inert. The usual methods for detg. the pigments were employed. Co was detd. colorimetrically when less than 10 γ per ml., with a 1% soln. of 1-naphthol-2-nitroso-4-sulfonic acid. Under conditions outlined Co can be detd. down to 0.0003%. Three tables show the results. W. H. Boynton

Moisture peeling of house paints. Effect of structural details. J. W. Iliff and R. B. Davis. *Ind. Eng. Chem.* 31, 1407–12(1939); cf. following abstr.—A test house with interior humidified and thermostatically controlled is described for studying moisture peeling of house paints. For studying moisture peeling caused by condensation of inside moisture the house is effective only during cold weather. Use of tar paper (kind of tar paper not reported) between siding and sheathing does not prevent moisture failure. Blocking of air circulation in walls behind painted areas by fire stops or with insulation increases the danger of moisture peeling of the paint. Use of effective vapor barriers properly placed in exterior walls and attic floors protects against moisture peeling. Circulation of external air immediately behind painted woodwork, as by furring out and venting siding, is very effective in preventing moisture peeling but somewhat impairs thermal insulation. F. L. Browne

Condensation problems in modern buildings. L. V. Teesdale. *Illinois Eng. Expt. Sta. Circ.* 37, 104–17 (1939); *U. S. Forest Products Lab. Mimeograph* R1196; cf. preceding abstr.—Temp. and vapor pressure gradients through sidewalls as affected by permeability of the building materials to moisture and by thermal insulation are discussed and illustrated on the basis both of the theory and of studies made with the Forest Products Lab. test house. Comparative resistance of common building materials to vapor transmission is tabulated. Proper installation of vapor barriers permits enjoyment of the economies and comforts of modern methods of construction without danger of damage to the structure, and incidentally to the exterior paint, from condensation within the sidewalls. F. L. Browne

Chlorinated rubber paints and varnishes. F. Sarx. *Fette u. Seifen* 46, 580–3(1939).—Further discussion (cf. *C. A.* 33, 2353[6]) emphasizes the ability of protective coatings formulated with chlorinated rubber to withstand attack by chemicals and to serve as anticorrosive coatings. Formulation with and without drying oils is discussed. J. W. Perry

Fire prevention in paint and varnish plants. Kenneth Tyson. *Am. Paint J.* 24, Convention Daily, 8(Nov. 3, 1939).—Causes of such fires are: (1) spontaneous combustion, (2) flashing of materials which have been heated beyond their ignition point and (3) flashing of combustion vapors generally set off by sparks. The Fognozzle is a nozzle that breaks the water supply into extremely fine particles evenly distributed over a given area and being steam immediately upon hitting the fire and because of its great expansion in vol. in conversion to steam the amt. of available O to permit combination is greatly lessened. W. H. Boynton

The influence of variations of barium sulfate extender particle size on the hiding power of titanium dioxide paints. Henry D. Piper. *Am. Paint J.* 24, Convention Daily, 17, 18, 20–1(Nov. 2, 1939).—A study was made of the hiding power of paints consisting of 75% boiled linseed oil and 25% solids (TiO_2 and $BaSO_4$) by vol. For each $BaSO_4$ sample of different particle size, paints were prepd. in which 85%, 75%, 65% and 50% of the total vol. of solids present were sulfate. The remainder of solids was TiO_2. The total vol. was always 25% of the total vol. of the paint. The most general conclusion is that in TiO_2-$BaSO_4$ system paints up to about 35% TiO_2 concn. of pigment vol., there is no indication that variations of $BaSO_4$ particle size have any effect whatsoever on hiding power. At concns. above 35% slight discrepancy is evident in the curves of the graph and this may possibly be somewhat larger above 50%. There was no indication that the larger sulfate particles provided better hiding power—the coarsest size tried apparently decreasing the hiding considerably. No adsorption of TiO_2 to sulfate surface is apparent. The effect of adding $BaSO_4$ extender seems to be only to decrease the hiding of the actual pigment in proportion to the vol. of extender present in the paint. W. H. B.

Primers for nonferrous metals—Golden Gate Paint & Varnish Production Club. Harry Eastwood, *et al. Am. Paint J.* 24, Convention Daily, 11, 12(Nov. 1, 1939).—A study of the primers for Al and Mg and their alloys, particularly those used in airplane construction. The finishing procedure was one coat of primer over the entire panel, followed after drying 1 week in the lab. by one finishing coat over 80% of the panel. Primer coats were sprayed. The finish coat in all cases was made by adding a lb. of standard Al paste to 1 gal. of Navy VIOC spar varnish. Twenty-six references. W. H. Boynton

Effect of pigment concentration on hiding power of white pigments—Baltimore Paint & Varnish Production Club. E. B. Schuler, *et al. Am. Paint J.* 24, Convention Daily, 14–15, 16–17(Oct. 26, 1939).—A study was made of several pigments at a no. of pigment-binder ratios by a method which expressed the results in fundamental phys. units easily duplicable. The method is outlined and results are tabulated for 7 pigments. The following general conclusion is: (1) it is futile to attempt to assign abs. hiding values to pigments either from exptl. data collected under one set of conditions or values derived from optical or empirical calcns., (2) the hiding power of a given wt. of pigment is different at different pigment concns., (3) there is a pigment concn. where a given wt. of pigment has a min. hiding power as the pigment concn. is increased or decreased (from this point there is an accompanying increase in hiding power for the given wt. of pigment) and (4) the relative hiding power varies depending not only upon the pigment-nonvolatile ratio but also upon the thickness at which the paint is to be applied. W. H. Boynton

The wetting of pigments by linseed oils and paint vehicles. Charles A. Murray and F. E. Bartell. *Am. Paint J.* 24, Convention Daily, 17, 18, 20–1(Nov. 3, 1939).—The effect is indicated of the adsorbed layer on the wetting and dispersion of pigments in linseed oil. A no. of different processes which depend upon the wetting characteristics of the liquid phase, and the results of the different expts. have been compared and correlated. The interfacial tension of linseed oils against water of oil absorption values of the same oils against standard pigments, of sedimentation vols. of the pigment in the oils, of grinding and dispersion of the pigments in the oils, and of the wetting characteristics of adsorbed layers of the oils on the pigment surfaces.

It seems certain that adsorbed layers of constituents from the oil affect every process in which a pigment or other solid becomes wetted by a drying oil or one of the usual paint vehicles. W. H. Boynton

Nonchalking titanium dioxides. R. L. Wharton. *Am. Paint J* 24, Convention Daily, 8(Nov. 3, 1939). W. H. Boynton

Some new slants on dry colors. D. H. Parker. *Drugs, Oils & Paints* 54, 378-9, 380, 381-2(1939).—See *C. A.* 33, 7599[2]. W. H. Boynton

Pigment pH value. A. H. Stuart. *Paint Manuf.* 9, 306-9(1939).—Light from an ordinary elec. lamp bulb is made to pass vertically down a 50-cc. Nessler tube in a dark box, a suitable diaphragm being placed above and below the tube. The emerging light falls on a photoelec. cell which operates a microammeter. The device is standardized for pH measurements by means of a series of solns. of known pH values contg. Universal indicator. The pigment is shaken with a measured quantity of distd. water and filtered through a paper known to be neutral. W. H. Boynton

Oxidation of vegetable drying oils. The ketol and peroxide groupings. R. S. Morell and E. O. Phillips. *Fette u. Seifen* 46, 541-6(in English)(in German, 546 *bis*)(1939).—Work by M. and others on the reaction mechanism of drying oil oxidation is reviewed. In general, the "remote" double linkages form peroxides whose rapid polymerization leads to gel formation, while the "neat" double bonds oxidize more slowly to form peroxides which gradually pass over into a ketol linkage. 28 references. Cf. *C. A.* 29, 8374[1]; 30, 6224[2]. J. W. Perry

Some studies in the drying of vegetable oil films. L. L. Carrick, G. E. Knudson, J. V. Porter and H. J. Thompson. *Am. Paint J.* 23, 58, 60-2(May 1, 1939).—A review of the literature on means of studying gain in wt. of objects on which oil films were drying. Conditions were not identical for all observers. *Ibid.* 18, 21, 56, 58, 60(May 15, 1939).—The various structures accredited to tung oil are shown. The principal unsatd. acids formed in perilla, linseed and the semidrying oils are oleic, linoleic and linolenic. Eleostearic, linoleic and linolenic acids are the important acids as regards the oxidation of drying oils. Their behaviors toward O are indicated. *Ibid.* 54, 56, 58, 60, 62(May 29, 1939).—Largely a review of the work of other investigators. *Ibid.* 14, 16, 18(June 12, 1939).—Further reviews. *Ibid.* 21-4(June 26, 1939).—Phys. and chem. consts., chem. analysis and combustion analysis are shown for raw tung, perilla and linseed oils. *Ibid.* 16, 18, 21, 44-5(July 10, 1939).—In studying the drying the film thickness was calcd. from the wt. of the oil, the area and the sp. gr. of the oil. The combustion-train assembly is pictured and curves show: percentage increase in wt. of raw tung oil films with age and the same data for raw perilla and raw linseed; and the relation of age of raw tung films to the percentage of O found by combustion analysis on each of these oils. *Ibid.* 45-50(July 31, 1939).—A study of films without drier. Changes undergone in the tung oil in assuming the solid phase and those in the subsequent aging of the film are slow enough to emit a deeper insight into the mechanism involved, from an application of the accumulated data. Complete frosting required 69-72 hrs. The Br no. curves for films without drier are peculiar because it appears as though the amt. of unsatn. increases with the O absorption instead of decreasing—a phenomenon that can be explained by assuming that the steric conditions which prevent addn. of Br to the 3rd double bond of eleostearic acid in the original oil are removed by the addn. of a slight amt. of O. On this basis the O absorption of the film at the max. Br no. has been calcd. The theoretical Br no. of the unoxidized oil is 231.4 if addns. occurred at all 3 double bonds. The max. Br no. at 2.5 days is 204. The relations between age of raw tung oil films and Br no., thiocyanate no. and the corrected diene no. are shown in curves. *Ibid.* 16-17, 43-5(Aug. 14, 1939).—Curves show: the relation between age of raw tung oil films and peroxide no., also the relation between film age and sapon. no. and acid no. with similar information for perilla oil films. The I nos. are lower than the thiocyanate nos. probably because the peroxides rearrange to give some ketones. The thiocyanate then adds to the enol form of these ketones, but the Wijs soln. does not add on as it is not in contact with the film long enough to cause an appreciable amt. of the ketone to be shifted to the enol. *Ibid.* 46-7, 50-1(Aug. 28, 1939).—The relation between the age of raw perilla oil films and acetone-insol. and the relation between the age of these films and sapon. no. and acid no. are indicated. The research on these films neither proves nor disproves any of the existing theories as the mechanism of the 2nd step in the drying process but indicates that the process is colloidal. The percentage compn. and I no. of the film and of the acetone-insol. portion of the film are essentially the same. *Ibid.* 16, 18, 21-2, 53, 56-8(Sept. 11, 1939).—Exptl. data show that the actual max. increase in wt. of a vegetable oil film based on the total C and H content of the dried film is much larger than that obtained on the basis of every possible double bond being satd. with peroxide O. Discrepancies obtained by comparing the results obtained when based on the I no. and on the combustion analysis detn. indicate that an addnl., and as yet little suspected, type of O absorption has taken place which cannot be ascribed entirely to peroxide formation at the original double bonds. The excess O may be adsorbed according to the gas coagulation theory of secondary O added to new double bonds formed by keto-enol shifts. Curves show: the relation between age of raw linseed oil films and the peroxide O, the I no., the acid no., sapon. no., the thiocyanate no. and the percentage of acetone-insol. A table is included of diene no. (maleic anhydride value) of raw linseed oil fims without drier. Four general conclusions are: (1) the driers merely acted as an oxidation accelerator—the only difference being in the rate of oxidation and absorption, (2) with raw linseed and raw perilla oils: (*a*) there is a discrepancy between the total O absorption and retention and the total amt. capable of being absorbed on the basis of peroxide formation at the original double bonds, (*b*) a theory is advanced for the increase in acid nos. and sapon. nos. in dried linseed oil or perilla films which is consistent with the excess O content noted in the oil, (*c*) the drying processes of raw linseed oil and raw perilla-oil films consist primarily of oxidation followed by colloidal assocn. rather than polymerization, (3) in raw tung oil (*a*) the combustion analysis, the Br no., the thiocyanate no. and the diene no. of dried oil films all show that the oxidation of the 1st two double bonds of eleostearic acid is rapid and the oxidation of the 3rd much slower, (*b*) the diene no. shows that the center double bond of the conjugated system of eleostearic acids was still open after the addn. of 1 mol. of O, (*c*) oxidation of the 3rd double bond results in the evolution of volatile products and in the formation of products sol. in acetone, (*d*) acid and sapon. nos. indicate that the oxidation of the 3rd double bond resulted in the formation of acids and compds. that were sapond. to a greater extent than the original triglycerides, (*e*) the oxidation products from max. O absorption correspond to the addn. of 2 atoms of O to each of the double bonds of the eleostearic acid and the linoleic acid-glyceride present and (4) an explanation of the increase in sapon. nos. and acid nos. appearing to be consistent with observed data. Bibliography. W. H. B.

Chinawood-oil substitution. Wm. A. Gerhardy. *Am. Paint J.* 24, Convention Daily, 8(Nov. 3, 1939). W. H. Boynton

Proximate analysis of hydrocarbon thinners. II. Philadelphia Paint & Varnish Production Club. *Am. Paint J.* 24, Convention Daily, 23-4(Nov. 3, 1939); cf. *C. A.* 33, 885[2].—To improve precision and thoroughly to test accuracy, extn. of aromatic substances by silica gel was substituted for treatment with fuming H_2SO_4 in dealing with low-solvency thinners. Synthetic blends were analyzed. Methods of analysis are outlined. Refractive indexes are tabulated for com. thinners. Proximate compns. in percentage of the whole thinner are tabulated for 4 blends. W. H. Boynton

The measurement of adhesion of dried coatings—New York Paint & Varnish Production Club. Robert J. Moore,

et al. Am. Paint J. **24**, Convention Daily, 18, 19, 20–1, 22–3 (Oct. 26, 1939).—An outline tending to classify the important quant. methods devised for measuring adhesion, and a sep. treatment of each type of test covering its salient features, technique and possible value as a standard method. Three methods studied experimentally are: (1) tensile method involving elongation of the base, (2) tensile method involving direct measurement of force needed to strip the film from the base and (3) a knife method involving an instrument for quant. measurement of the knife pressure required to strip the film from the base.

W. H. Boynton

Varnish losses in weight and in volume—Chicago Paint & Varnish Production Club. R. J. Gnaedinger, *et al. Am. Paint J.* **24**, Convention Daily, 12–13 (Oct. 26, 1939).—Losses in wt. and in vol. occurring during the heat processing of varnish were studied. Ten typical resins and 2 drying oils were included. There is less consistent indication of vol. shrinkage when oils are thinned with mineral spirits or xylene than with resins and results indicate no shrinkage. The max. shrinkage of varnish bases is 0.5%, the av. being 0.2%. In general, any shrinkage in vol. occurring when an oleoresinous base is thinned is too slight to be of practical interest. Most of the resins become less soln. and give more viscous and darker solns. as working time and temp. are increased. Notable exceptions, giving lower viscosity with heating, are maleic esters, one modified phenolic resin and coumarone resin

W. H. Boynton

A study of natural resins in combination with synthetic resins for floor varnishes—New England Paint & Varnish Production Club. B. H. Kropel, *et al. Am. Paint J.* **24**, Convention Daily, 12–13, 14–15, 16 (Nov. 2, 1939).—The properties of 6 natural, 4 treated natural and 4 synthetic resins were studied, also certain blends. Better wearing varnishes can be made by utilizing the good adhesion and wearing qualities of the natural resins, pale East India, Batu, Pontianok and esterified Congo. Modification of these natural resins with low percentages of phenolic resins, except heat-reactive phenolic, is desirable with a view to increase water-, alkali- and gas-checking resistance. Test methods and cooking methods are reviewed.

W. H. Boynton

"A viscosity reduction method" for commercial evaluation of hydrocarbon solvents for synthetic varnish resins—Los Angeles Paint & Varnish Production Club. Ralph H. Huff, *et al. Am. Paint J.* **24**, Convention Daily, 12–15, 16 (Nov. 1, 1939).—The two variables used for purposes of solvent power expression should consist of: (1) a solvent compatible with the dissolved material but of relatively weak actual solvent power and (2) a very high strength of a type known to be compatible with a wide variety of substances used by the industry. Phenolic and modified phenolic resinous products were investigated. Expts. were performed with oil-dispersed resinous bases. All modified phenolic resins were dispersed by a method common to standard varnish practice in an equal wt. of heat-bodied linseed oil. With 100% phenolic resins, the oil-to-resin proportion was 3 parts by wt. of bodied linseed oil and 1 part by wt. of the resin. By computing the solution to the bases of nonvolatile and volatile content by vol. the graphs drawn on semilogarithmic graph paper were consistently uniform curves. Several curves showing percentage solids by vol. and viscosity in poises are given and tables give inspection data relative to: limed rosin and ester gum modified phenolic resins, oil modification of these and solvents used in prepg. viscosity test solns. Conclusions drawn from the investigation are: (1) solvent strength of hydrocarbon thinners can be reliably measured by detg. the effect of solvents upon a compn. of a type similar to that which it is intended that the solvent is to dissolve in actual practice, (2) solvent strength of any given solvents or combinations are a function of an area bounded by a graph of viscosity *vs.* nonvolatile by vol. relative to a selected base lime, (3) viscosity characteristics of semicolloidal solns. (or dispersions) are a function of relative vols. of various components, not of relative wts., (4) viscosity measurements of varnish oils and resin base solns. are a direct logarithmic function of the vol. of nonvolatile within the viscosity ranges at which these materials are customarily used, and for purposes of solvent strength calcns. should be plotted on semilogarithmic paper. A complete correlation between the viscosity-reducing character of solvents and "aniline point" does not seem to be indicated, at least insofar as the solvents are used as varnish thinners. Exptl. procedure is appended.

W. H. Boynton

Effect of resins on kauri reduction—Louisville Paint & Varnish Production Club. A. E. Rheineck, *et al. Am. Paint J.* **24**, Convention Daily, 11, 12 (Oct. 26, 1939).—Kauri reduction values of varnishes made with several resins and oil lengths are tabulated and plotted. The zero reduction values of these resins were found, the kauri reduction values of several oils detd. and all resins except 100% phenolics shown to have an embrittling action on oil greater than might be expected.

W. H. Boynton

Cellulose derivatives in lacquers. C. Maters. *Oil Colour Trades J.* **96**, 919–21 (1939).—The compatibility of cellulose derivs. with resins generally varies inversely with the degree of polymerization of the resin. They are particularly useful with the oil-modified resins because of their effect of increasing the rate of drying of the film. Cellulose acetate, mixed esters and cellulose ethers are discussed, also water emulsions of lacquer bases. It is claimed that these lacquers may be applied at the high solids concn. of synthetic resin finishes with resultant elimination of baking ovens and a lacquer which sands and patches easily.

W. H. Boynton

Paints. Robert S. Edwards (to Rumford Chemical Works). U. S. 2,172,997, Sept. 12. A vehicle such as drying oils and turpentine and a pigment such as TiO_2, ZnO and white lead are used with a pigment "extender" consisting of a noncatalyzed, nondissocd. $CaSO_4$ derived from a gypsum or anhydrite treated prior to calcination at temps. of 980–1260° substantially to eliminate anhydrite recrystn. and dissocn., which on application of the paint is catalyzed by the pigment to form a toughened paint film.

Paint compositions containing casein, etc. Joseph V. Reardon (to Reardon Co.). U. S. 2,174,094, Sept. 26. A dry powd. paint compn., which when mixed with water, applied and dried becomes washable, comprises casein and a water-sol. aluminate, such as that of Na, Ba or Ca, which is active both as a solubilizer and insolubilizer for the casein and which is of substantially neutral reaction, the compn. being substantially devoid of ingredients which after being mixed with water, applied and dried, are sol. in water.

Treating wool fat to form paint bases. Howard W. Smith and Sydney G. Campbell. Brit. 507,337, June 14, 1939. The unsaponifiable matter from wool grease is heated to 500°F. with caustic alkali or other condensing agent, e. g., $CaCl_2$, anhyd. $CuSO_4$, $ZnCl_2$, $Ba(OH)_2$, to improve its drying properties; if saponifiable matter is

present, a nonbasic condensing agent is used. The products may be mixed with drying oils to form a paint.

Pigments. Mrs. Else Albert (trading as Vereinigte Werke Dr. Rudolf Alberti & Co.). Brit. 507,472, June 12, 1939. In the production of white paints contg. aq. binders, H_2O-insol. mineral substances, e. g., heavy spar, limestone, chalk, marble, fluorspar, celestine, witherite, are ground to a fineness of about 60% below 2 μ and the ground product is mixed as a pigment (as opposed to a filler) with the binder and H_2O.

Pigments. I. G. Farbenind. A.-G. (Ekbert Lederle and Max Günther, inventors). Ger. 679,959, Aug. 17, 1939 (Cl. 22*f*. 3). A light-fast chrome-yellow pigment is prepd. by pptg. a Pb soln. with a chromate soln. and heating the suspension to cause the mixed crystals of $PbCrO_4$ and $PbSO_4$ to change from the rhombic to the monoclinic form. The solns. are caused to react at below 60°. Thus, an aq. soln. of $Pb(NO_3)_2$ is treated with an aq. soln. of $K_2Cr_2O_8$, K_2CrO_4 and K_2SO_4 at 15°. The resulting suspension is heated to about 60°. On sepg. and drying the ppt. a greenish chrome-yellow pigment is obtained.

Grading pigments. Bird Machine Co. Brit. 507,700, June 20, 1939. Pigments or extenders, e. g., lithopone, ZnS, TiO_2, $CaSO_4$, $BaSO_4$, that are prepd. by processes involving pptn., calcination and ball-milling in the presence of H_2O are further treated by centrifuging the pigment suspension from the ball mill under substantially const. solid-depositing conditions and under substantially const. effective centrifugal force to remove coarse particles, which may be returned to the ball mill, and obtain a suspension of the fine particles from which a pigment whose particles may be less than 2 μ in size is recovered. Centrifuging may be effected in a continuous-flow centrifuge of the type shown in Brit. 484,992 (*C. A.* **32**, 7785[8]) and recovery of the fine pigment effected either by the continuous electrophoretic centrifuging treatment described in Brit. 456,353 (*C. A.* **31**, 2051[6]) or by treatment with a flocculating agent, e. g., $MgSO_4$, followed by centrifuging or filtration on a rotary filter or in a filter press.

Iron oxide pigments. Willy Glaser. Brit. 507,316, June 13, 1939. Fe oxide is prepd. by the thermal decompn. of $FeSO_4$ in the presence of H_2O-insol. cellulosic substances, e. g., sawdust, waste paper, straw, waste textile materials. Thus, 1000 l. of cold satd. $FeSO_4$ soln. is heated at 70° in an agitator tank and $FeSO_4$ 4000 and sawdust 3000 kg. are added. After complete soln. of the $FeSO_4$, the mass is cooled while being stirred and the sawdust impregnated with fine crystals is centrifuged and decompd. in known manner by being heated to redness in an excess of air; the product is dried and ground. In a modification, 400 kg. of $ZnSO_4$ is added to produce a yellowish red Fe oxide, the $ZnSO_4$ being recovered by being washed from the product of the thermal decompn.

Lead chromate pigments. Omar F. Tarr and Winslow H. Hartford (to Mutual Chemical Co. of America). U. S. 2,173,457, Sept. 19. A process of producing Pb chromate pigments comprises gradually adding, to a rapidly agitated suspension in water of a Pb oxide, carbonate or hydroxide, a mixt. of an acid and a chromate or dichromate, in an amount and in proportions sufficient to convert the Pb compd. into the desired pigment, the mixt. being added at a rate not exceeding the rate of soln. of the Pb compd. so as to maintain an alk. reaction in the suspension throughout the process, the amt. of water in the suspension being sufficient to permit substantially complete reaction of the difficultly sol. basic Pb compd.

Titanium oxide pigment. Henry A. Gardner. U. S. 2,172,505, Sept. 12. About 0.15–1.0% of phthalic anhydride is used with a Ti oxide pigment.

Titanium pigments. Titan Co., Inc. Brit. 507,506, June 16, 1939. Addn. to 499,153 (*C. A.* **33**, 5209[6]). In the production of stable white TiO_2 pigments, with modified color tone, by a process including the step of calcining a Ti pigment contg. a trace of W and (or) Mo, the Ti pigment contg. the W and (or) Mo is exposed to reducing conditions at 700–1000° for a short time only while the pigment is being calcined, while cooling subsequent to calcination or during a special reheating of the calcined pigment. Reducing conditions may be obtained by providing an atm. of H, CO or water gas, or by adding a small amt. of carbonaceous material that liberates reducing gases on ignition. The process is applicable also to the production of composite Ti pigments, e. g., TiO_2-$BaSO_4$ and TiO_2-$CaSO_4$ pigments.

Improving the color of off-color cadmium red pigments. James J. O'Brien (to Glidden Co.). U. S. 2,173,128, Sept. 19. The particles of an off-color Cd sulfide selenide pigment are coated with pptd. Cd sulfide selenide and the mixt. is calcined.

Sulfide pigments. James E. Booge (to E. I. du Pont deNemours & Co.). U. S. 2,173,895, Sept. 26. A process for producing an insol. sulfide pigment compn. involves treating in aq. soln. an alk. earth metal thiosulfate such as that of Ca with a sol. salt of Zn, Cd or Sb, heating a soln. of the resultantly formed thiosulfate compd. and effecting its decompn. in the substantial absence of SO_2 evolution and in the presence of an alk. agent such as lime adapted to neutralize the acidity which develops during the decompn., and recovering the pptd. pigment.

Pigmented resin base for paints, etc. Max R. Vogel (to Binney and Smith Co.). U. S. 2,173,430, Sept. 19. A ground intermixt. is formed of a pigment such as carbon black with a solid, plastic, water-insol. resin such as an alkyd resin, and a stable, sol., org. amine contg. a plurality of unsubstituted —NH_2 groups, such as triethylenetetramine, which serves as a dispersing agent for the pigment.

Cellulose ether pigmented base suitable for use in lacquers, etc. Robert L. Zapp (to Binney and Smith Co.). U. S. 2,173,444, Sept. 19. A product suitable for various uses comprises a ground intermixt. of C black with a plasticized cellulose ether such as cellulose ethyl or benzyl ether, plasticized as with dibutyl phthalate and Ni soap dispersing agent such as Ni oleate sol. in the cellulose ether mass. U. S. 2,173,445 relates to similar compns. contg. a soap of Ca, Ba or Sr, such as Ca palmitate or Sr oleate.

Ink for transparent projection strips. Millard Demarest and Kirtland Flynn (to Celluloid Corp.). U. S. 2,172,465, Sept. 12. An ink adapted for use in printing on transparent strips such as those of cellulose acetate consists of a coloring material such as Methyl Violet dispersed in a liquid consisting of a nonhygroscopic solvent plasticizer for cellulose derivs. and which may be triacetin, an ethyl toluenesulfonamide, dimethyl phthalate, dibutyl tartrate or monomethyl xylenesulfonamide.

Polymerized fat acids. N. V. Industrieele Maatschappij Voorheen Noury & van der Lande. Ger. 679,875, Aug. 15, 1939 (Cl. 12*o*. 26.02). Drying or semidrying oils are polymerized and the fats sepd. from the product, or the fat acids are sepd. from the oils and then polymerized. The mixt. of polymerized and nonpolymerized fat acids are subjected to distn. *in vacuo*, with or without the aid of steam, to remove the nonpolymerized acids. The polymerized acids remaining may be converted to their glycerides by esterification. In examples, linseed and soybean-oil fat acids are polymerized.

Drying oils. I. G. Farbenindustrie A.-G. Brit. 507,786, June 21, 1939. The drying properties of oiticica oil are improved by treating it with the theoretical amt., or less, of semicarbazide (I), or a deriv. thereof, to react with the keto group in the oil. The raw oil or heated oil (stand oil) or mixts. thereof with other drying oils may be treated and thio-I, aminoguanidine or I-HCl and a basic substance may be used instead of I.

Naphthenate driers. Arthur Minich. Brit. 507,361, June 14, 1939. Basic salts of naphthenic acid with drying metals, e. g., Co, Mn, Pb, are prepd. by causing a soln. of an alkali metal naphthenate contg. free alkali to react with a H_2O-sol. salt of the metal contg. sufficient metal to combine with the naphthenic acid and react with the free alkali present. After being washed and dried, the pptd. basic salt is obtained as a powder insol. in oil or H_2O and, by reason of its high metal content, it forms an efficacious drier, particularly for printing inks.

Varnish coatings on wood. Wilhelm O. Maisch (to

Firma Hermann Frenkel). U. S. 2,174,132, Sept. 26. A process for producing water- and weather-resistant coatings on wood involves coating the wood with a varnish consisting of a soln. in an org. solvent of a mixt. of a hardenable phenol-formaldehyde resin obtained by alkali condensing one mol. of phenol with at least 1.5 mols. of CH_2O together with an artificial resin from the urea-aldehyde resin group amounting to 5–100% calcd. on the phenol-formaldehyde resin and with an acid hardening agent, and hardening the resin mixt. in the air at normal temp.

Coating compositions. Howard W. Smith and Sydney G. Campbell. Brit. 507,335, June 14, 1939. A coating compn. or paint vehicle includes, as essential ingredients the unsaponifiable matter of wool grease, which has been subjected to the action of caustic alkali or other condensing agent at a high temp., and a Mg soap, e. g., that produced from wool grease fatty acids, Mg resinate.

Coating compositions. Hardman and Holden Ltd., Howard W. Smith, Sydney G. Campbell and Henry S. Land. Brit. 507,336, June 14, 1939. Wool grease is heated with oxide or hydroxide of Ca, Sr, Ba or Mg, without added H_2O, whereby the neutral esters contained are sapond. The product has drying properties and may be used for coating or impregnating compns.

Composition for coating or impregnating porous materials. Ivor M. Colbeth (to Baker Castor Oil Co.). U. S. 2,172,955, Sept. 12. A substantially solidified castor oil which may be prepd. by oxidation or sulfurization and which is insol. in ether, alc., acetone, C_6H_6, CS_2, water and turpentine is used with sufficient alkali ricinoleate to form an emulsion when dild. with water.

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

The present status of the Italian fat and fat-product industries. St. Fachini. *Fette u. Seifen* **46**, 518–19(in Italian)(in German, 519–20)(1939).—Recent developments are (1) increased domestic production of fats with import requirements reduced by a third and (2) modernization and expansion of Italy's fat-processing industry. J. W. Perry

The oxidation of fats. E. Glimm. *Fette u. Seifen* **46**, 348–50(1939).—This lecture reviews modern theories concerning reactions involved in the rancidification of fats, their catabolism in the animal body and film formation by oxidation of drying oils. Forty references. J. W. Perry

The bleaching of fats and the recovery of oils from bleaching earths in relation to the problem of obtaining the highest possible yields of edible fats when refining raw oils F. Wittka. *Fette u. Seifen* **46**, 344–5(1939).—When bleaching earths are used to refine fatty oils, it is poor practice to attempt to recover the last drop of oil from the bleaching earth press cake by prolonged blowing with air, as the oil so recovered is partially oxidized and very susceptible to rancidification. To avoid such impairment of quality, the press should be blown with low-pressure air for a short time only and the oil then remaining in the bleaching earth press cake recovered by extn. and recycled through the refining process. J. W. Perry

A note on the estimation of fat in cacao. E. C. Humphries. *Ann. Rept. Cacao Research* **8**, 39–40(1938)(Pub. 1939).—Three 5-g. portions of a very carefully ground sample of cacao were extd. with petr. ether (b. 50–60°) for 20 hrs. in the usual manner. The values for fat thus obtained were 52.74, 52.14 and 53.35%. The residues from the petr. ether extn. were each mixed with 2.5 g. freshly calcined MgO and then further extd. with $CHCl_3$ for 20 hrs. Addnl. quantities of fat, detd. by subtracting the wt. of total alkaloids extd. by the $CHCl_3$, amounting to 2.08, 2.73 and 1.60%, resp., were obtained and the values for total fat were brought into much better agreement. Extn. with petr. ether alone for 40 hrs. gave values that were approx. 1% higher than those obtained by extn. for 20 hrs. with this solvent. The fat fraction extd. by $CHCl_3$ appeared to be different from ordinary cacao fat and tended to darken on keeping. K. D. Jacob

Changes in fat and theobromine content of the kernel of the cacao bean during fermentation and drying. E. C. Humphries. *Ann. Rept. Cacao Research* **8**, 34–6(1938)(Pub., 1939).—The fat content of the fermented beans increased until about the 5th day, with a total increase of approx. 4% on the oven-dry basis. Sun-drying after fermentation caused a slight decrease in fat. The fat content of beans that were sun-dried only did not alter appreciably. The theobromine content decreased during fermentation and tended to reach a const. value in 12 days. When the beans were sun-dried after fermentation, the theobromine content increased slightly. The theobromine content increased in beans that were subjected only to sun-drying. K. D. Jacob

International standardized fat analysis methods. H. P. Kaufmann. *Fette u. Seifen* **46**, 499–517(1939).—A detailed description is given in both the Ger. and French languages of the methods standardized to date, namely, (1) for oils and fats, d., *n*, water and volatile components, impurities, acidity, ash content, insol. fat acids, sapon no., unsaponifiable content, oxidized acids, I no., poly bromide no., OH no. and (2) for soaps, taking of sample, moisture content, alc.-insol. components, total fat acid content, total alky. and total free alky. J. W. Perry

Determination of fats in shoe wax. M. M. Katsin *Kozhevenno-Obuvnaya Prom.* **18**, No. 6, 26–7(1939).—Heat a 5-g. sample of the shoe wax with 50 ml. distd. water in a porcelain cup, add 15 ml. HCl (1.19) and boil for 1 hr. Filter while hot (with decantation), wash the residue with hot water until the filtrate is colorless, dry to const. wt., and ext. in a Soxhlet app. with petr. ether. The results were 2–3% above the actual values but these were within exptl. errors. B. Z. Kanich

The determination of fats in fatty products used in baking. H. Schmalfuss. *Fette u. Seifen* **46**, 331–3(1939).—A compn. consisting of rape oil 8, tallow 39, Palsgaard oil (I) (an emulsifying oxidized, polymerized oil product) 3, skim milk 10 and an 80% glucose soln. 40% was analyzed for fat in the usual way by rubbing up with anhyd. Na_2SO_4 and extn. with ether. Only 48% fat was found. Systematic search for the cause of this low result showed (1) that extn. with benzene or $CHCl_3$ gave more nearly the correct result than extn. with ether owing to poor soly. of I in ether and (2) that the low result was caused by the sugar soln. preventing complete extn. of I by any of the solvents used. J. W. Perry

Determining the unsaponifiable in fats and oils. W. Holwech. *Fette u. Seifen* **46**, 551–4(1939).—Exptl. data show that increasing the concn. of soap in the aq. phase increases the ratio, concn. of unsaponifiables in the soap soln. to concn. of unsaponifiables in the ether used for extn. Hence, complete extn. of the unsaponifiables from a more concd. soap soln. requires greater no. of extns. or larger amts. of ether per extn. or both. Limitations as to accuracy in weighing small amts. of unsaponifiables with an ordinary balance, the inconvenience of handling large vols. of aq. soap solns. and the desire to reduce ether consumption to a min. are factors also considered. For ordinary work, the method (cf. *C. A.* **32**, 9536[1]) of using 3 extns. with 180 cc. of ether in all and double sapon. is recommended. With such a method, 1.54–1.59% unsaponifiables were found in a whale-oil sample contg. 1.63%. For greater accuracy, use of a continuous extn. app. is recommended. The soap concn. of the aq. phase should be kept below 8 g. per 100 cc. as otherwise excessively long extn. periods are necessary. J. W. Perry

The ability of monel to withstand corrosion in the oil and fat industry. R. Müller. *Fette u. Seifen* **46**, 346–8(1939).

—Tabulated data show the excellent resistance of monel to corrosion by fat acids, caustic, H_2SO_4 and fats. Since monel also has very high mech. strength and good weldability, it is very desirable as a material for construction in the oil and fat industry. J. W. Perry

New machines and apparatus for the oil, fat and cosmetic industry. A direct-action emulsifying machine. W. Meyer. *Fette u. Seifen* **46**, 359–60(1939).—The "Zenith" emulsifier turns out fine-grain emulsions directly from the component liquids without requiring preliminary prepn. of a coarse emulsion. J. W. Perry

The continuous extraction of seeds and suitable apparatus. K. Hildebrandt. *Fette u. Seifen* **46**, 350–2(1939).—This lecture discusses problems involved in (1) extg. from crushed oil seeds as much oil as is economically feasible, (2) recovering solvents in oil-extn. plants and (3) freeing the extd. seed pulps of residual solvent. J. W. Perry

The analysis of olive oil. G. B. Martinenghi. *Fette u. Seifen* **46**, 333–7(1939).—Various testing methods applicable to olive oil are reviewed with special attention to methods helpful in (1) detecting adulterations, (2) distinguishing between the different grades officially established in Italy (cf. *Gazzetta Ufficiale del Regno d'Italia*, Decree No. 1986, Sept. 27, 1936), and (3) estg. the proportions of such grades present in mixts. The significance to be attached to the various analytical results when a final conclusion is drawn is discussed. J. W. Perry

Detection of semidrying oils in olive oil. Vizern and Guyot. *Ann. fals.* **32**, 252–4(1939).—Free petr. ether b. below 70° of unsatd. hydrocarbons by shaking with concd. H_2SO_4 and distg.; to 100 cc. of the purified petr. ether cooled to 0° add about 4 cc. of Br, drop by drop, while stirring. Pour 1 cc. of the oil sample in a dry test tube (1 m. in diam.), dissolve in 10 cc. of petr. ether, allow to stand in an ice bath for about 15 min., add in small successive portions (with shaking) sufficient Br reagent (generally about 10 cc.) to ensure excess of Br (as shown by the brown color of the liquid); presence of a turbidity (due to pptn. of tetrabromides of linoleins) after standing for 1 hr. in an ice bath indicates the presence of at least 5% of soybean oil, 5% sunflower-seed oil or 10% corn oil.
A. Papineau-Couture

Some studies in the drying of safflower-oil films. L. L. Carrick and A. T. Murfin. *Am. Paint J.* **24**, 53–4, 56–8 (Oct. 23, 1939).—Films of uniform thickness were placed on plates and at predetd. intervals detns. were run as follows: net increase in wt., I no., thiocyanate no., peroxide no., Ac no., diene no., acid no., sapon. no., percentage of acetone insol., and ultimate analysis. Results are shown in curves. *Ibid.* 54–6, 58, 60(Nov. 6, 1939).—The increase in acid no. of oil films shows that free acids are being formed, probably by a cleavage of the peroxides or of the hydroxy compds. formed by rearrangement of the peroxides. The increase in sapon. no. seems to show that esterification of some type is taking place in the films as they dry. Explanation is offered of the mechanism of gelation. Curves show the relation between the age of raw safflower-oil films and the acid no., the sapon. no., the percentage of acetone insol., and the percentage of O obtained by difference from the combustion analysis.
W. H. Boynton

Sterols of alfalfa-seed oil. I. L. Carroll King and Charles D. Ball, Jr. *J. Am. Chem. Soc.* **61**, 2910–12 (1939).—Alfalfa seed (*Medicago sativa* L.), extd. with Et_2O, gives 11.8% of a greenish oil with n_D^{15} 1.4820. Hydrolysis of 100 g. of this oil with EtOH-KOH (refluxing 1 hr.) gives 4 g. of unsaponifiable material. Fractionation by crystn. from petr. ether gives a fraction (I) m. 164.4–4.8°; one (II) m. 160–1° and a 3rd (III) m. 155–6°; there remained 65% of the material as a reddish oil. Fraction I is either α-spinasterol (IV) or very closely related to it. The following desivs. of IV were prepd.: *acetate*, m. 180–1°; *benzoate*, m. 196–7°; *p-nitrobenzoate*, m. 211–13°; *phenylurethan*, m. 173–4°; *butyrate*, m. 123–5°. These check closely with values reported in the literature. Br in Et_2O or CS_2 transforms IV or its acetate into a sol. oil. II and III are probably mainly IV but the m. ps. of derivs. were lower than those of IV. C. J. West

Composition of the seeds of Sapindus drummondii. O. C. Dermer and L. T. Crews. *J. Am. Chem. Soc.* **61**, 2697–8(1939).—The seeds of *Sapindus drummondii* H. and A. (western soapberry or wild chinaberry) contain 23–4%, the seed kernels 42.7% of Et_2O-sol. materials. The oil was extd. with Et_2O or petr. ether or was pressed hydraulically. The oil was greenish brown to yellow-brown in color; it did not become rancid readily. The following values give the limits with different means of extn.: d_{25}^{25} 0.903–0.917, n_D^{25} 1.4704–1.4722, acid value 0.3–0.9, sapon. value 213–19, I no. (Hanus) 81.5–3.5, SCN no. 63.9–7.2, unsaponifiable matter 1.2%, Reichert-Meissl no. 0, Polenske no. 0, Ac value 14.5, unsatd. acids 74–7% (from I no.), 82% (by sepn. and correction for impurities), satd. acids 17–20% (from I no.) and 13% (by sepn. and correction for impurities). The air-dried exhausted meal contains 21.3% protein, 18% crude fiber, 3.7% ash and 8.4% moisture. The fatty acids present consist chiefly of oleic acid, accompanied by smaller amts. of linoleic, palmitic and stearic acids. C. J. West

Oil of Setaria italica Beauv. Hannemon Ito. *J. Agr. Chem. Soc. Japan* **15**, 879–84, *Bull. Agr. Chem. Soc. Japan* **15**, 134–5(1939). Analysis of German millet gave H_2O 12.83, ash 1.96, crude fat 3.55, crude protein 9.59 and starch 76.19%. One kg. of the oil was obtained from 33 kg. of powd. grains. The properties of the oils of glutinous and common German millet were, resp., d_{15} 0.9195, 0.9193; n_{30} 1.4710, 1.4710; acid value 51.95, 41.94; sapon. value 164.03, 159.60; I value 131.82, 105.07; Hehner value 93.30, 94.45; Reichert-Meissl value 0.43, 0.48; Polenske value 1.3, 1.4; Ac value 33.14, 31.37; unsaponifiable matter 2.13%, 2.39%; solid fat acids 17.40%, 15.05%; liquid fat acids 72.45%, 70.03%. Palmitic, carnaubic, oleic, linoleic and isolinoleic acid were isolated from the oil. Phytosterol and squalene were also found. Y. Kihara

Oil of Phaseolus vulgaris L. Hannemon Ito. *J. Agr. Chem. Soc. Japan* **15**, 885–90, *Bull. Agr. Chem. Soc. Japan* **15**, 135–6(in English)(1939).—When 16 kg. of *Phaseolus vulgaris* L. was extd. with hot ether, 195 g. of oil was obtained. The properties of the oil were: $d_{15.6}$ 0.9603, n_{30} 1.4808, acid value 20.5, sapon. value 132.6, I value 149.8, Reichert-Meissl value 1.03, Polenske value 2.00, unsaponifiable matter 7.0%, solid fat acids 19.0% and liquid fat acids 63.3%. A large amt. of palmitic acid and a small amt. of carnaubic acid were isolated from the solid fraction, while oleic, linoleic and linolenic acids were sepd. from the liquid fraction. The unsaponifiable matters were sepd. by their soly. in alc. into the easily sol. part m. 137–8°, $[\alpha]_D^{15}$ −33.6°, and the difficultly sol. part m. 151–3°, $[\alpha]_D^{15}$ −45.0°. Y. Kihara

Factors controlling the rate of oxidation of fish oils. J. Jánv. *Fette u. Seifen* **46**, 340–3(1939).—Films of sardine oil, herring oil, cod oil, whale oil and shark oil on raw sheepskin showed 6 to 15 times as much O_2 absorption as similar oil films on chrome leather or cotton batting. Similar relationships held also for herring oil contg. 0.1% 1.0% of Co linoleate drier (I). Evidently, the raw hide has an accelerating influence on oil oxidation reactions occurring during oil tanning. The effects of adding increasing amts. of I to herring oil on its oxidation rate during the first 6 hrs. were (1) a very great increase in the initial oxidation rate and (2) with amts. of I greater than 0.5%, a leveling off to a low rate of oxidation after attaining a degree of oxidation which was lower as the amt. of I was further increased. The rate of O_2 absorption of fish oil was reduced by sulfonating them or by addns. of free fish-oil fat acids or of mineral oil. J. W. Perry

Process for producing fish oil, tallow, meat scrap or fish meal. E. Langer. *Fette u. Seifen* **46**, 161–2(1939).—Extn. with di- or trichloroethylene is recommended as an excellent process for working up fish or other fatty animal material into oils and fats and valuable protein products.
J. W. Perry

The analysis of whale oil. E. Glimm and K. Giese. *Fette u. Seifen* **46**, 387–40(1939).—Whale oil (having the consts. d_4^{20} 0.92614, n 1.46178, sapon. no. 197.3, acid no. 5.1, I no. 111.9 (Kaufmann), 111.6 (Hanus), thiocyano-

gen no. 74.93, unsaponifiable 1.58%) was sapond. with exclusion of air, the satd. and unsatd. acids were sepd. by the Twitchell Pb soap methods, the free acids converted to their Me esters and then fractionally distd. The satd. acid esters were sepd. by repeated fractional distn. into fractions from which pure myristic, palmitic and stearic acids were obtained on sapong. The lower-boiling fractions of the Me esters of the unsatd. acids contained considerable amts. of esters of the satd. acids which were removed by the Twitchell method and the unsatd. acids then sepd. into mono-unsatd. and poly-unsatd. fractions by repeated partial pptn. of their Li soaps with acetone or alc. Mono-unsatd. acids contg. 14, 16, 18 and 20 C atoms per mol. were detected, the bulk of these acids being oleic and zoömaric acids. The only poly-unsatd. acids detected contained 20 or 22 C atoms per mol. Polybromides corresponding to the acids $C_{20}H_{32}O_2$ and $C_{22}H_{34}O_2$ were isolated. Owing to losses during distns., etc., no attempt was made to draw conclusions of a quant. nature. J. W. Perry

Some factors that affect the accuracy of the determination of the thiocyanogen value (of an oil). H. N. Sher and R. H. Coysh. *Analyst* **64**, 814–16(1939).—The main purpose of the expts. described was to det. to what extent variations in the length of time allowed for the interaction of oil and thiocyanogen affect the magnitude of the value obtained. The reagent used was prepd. by taking 12.5 g. of thoroughly dry $Pb(SCN)_2$ in a brown reagent bottle, adding 500 ml. of anhyd. AcOH and allowing the mixt. to stand for as long as possible before use. When needed, 1.5 ml. of pure Br_2 was added, the mixt. was shaken for an hr. and it was then filtered. Thus prepd., the reagent was clear and colorless. Quantities of oil from 0.1 to 0.14 g. were weighed into 250-ml. stoppered flasks and 20 or 25 ml. of the reagent was added at 20°. After standing in the dark for the specified time, the reaction mixt. was poured into 10 ml. of 10% KI soln. and titrated with 0.05 0.055 *N* $Na_2S_2O_3$. The reaction time was varied from 1 to 30 hrs. The results show that for olive oil, in which oleic acid constitutes about 80%, a max. thiocyanogen value was obtained in about 5 hrs. Almond oil and teaseed oil were preferably allowed a 15-hr. period and this time should be allowed for vegetable oils which have a high content of linolic acid relative to the content of oleic and other monoethylenic acid. For the more unsatd. oils, less satisfactory results were obtained but periods of 20–24 hrs. seem advisable. The reagent should not be more than 5 days old and a reaction period of more than 28 hrs. is inadvisable in all cases. W. T. H.

The evolution of the candlestick maker's trade into the wax industry. G. Buchner. *Fette u. Seifen* **46**, 160–1 (1939).—Historical. J. W. Perry

Extraction of soap solutions with ether. H. W. Weedon. *Fette u. Seifen* **46**, 400–1(1939).—See *C. A.* **33**, 7606[2]. J. W. Perry

The saponification reaction in the manufacture of soaps. L. Lascaray. *Fette u. Seifen* **46**, 533–6(1939).—German text of *C. A.* **33**, 9696[3]. J. W. Perry

Soap goes through the mill. V. A comparison of wetting agents and detergents. A. E. Hulme. *Textile Recorder* **57**, 46(Oct., 1939); cf. *C. A.* **33**, 8433[8]. A résumé of the methods of comparing these wetting agents and detergents. Proprietary products for various uses are listed. W. H. Boynton

Raw-wool treatment [soaps] (Williams) **25**. Washing, cleaning and polishing materials (Smither) **25**. Vegetable oils as Diesel motor fuels (Ilieff) **21**. Vitamin F [nature of certain unsatd. higher acids] (Grandel) **11E**.

Treating oils and fats to retard oxidation and the development of rancidity. Eastman Kodak Co. Brit. 507,471, June 12, 1939. Oxidation, etc., in animal and vegetable fats and oils are retarded by adding a quantity of a fraction, possessing antioxidant properties, taken from the 1st 20% of the distillate obtained by high-vacuum short-path distn. of vegetable oils or raw materials, e. g., seeds, nuts, from which said oils are derived, without hydrogenation. The process is particularly applicable to the treatment of lard, olive oil and of refined natural fats. The antioxidant may be derived from corn, soybean, cottonseed, wheat germ or apricot kernel oils. The antioxidant may, before use, be concd. and purified by redistn. under vacuum and may be purified by means of absorption agents or nondestructive chem. treatment.

Solvent extraction of seeds, etc. Hansa-Mühle A.-G. Brit. 507,465, June 15, 1939. In an extn. process wherein sieve-bottom containers holding the raw material mounted on an endless conveyor are treated with solvent, solvent is supplied to each container equals or exceeds the amt. passing out through the bottom so that the container is filled with solvent during a substantial part of the cycle. The outflow of solvent through the container is controlled by adjustable openings therein.

Extracting fish-liver oils. Gorton-Pew Fisheries Co. Ltd. Brit. 507,742, June 20, 1939. The preferably comminuted livers are treated with an alk. buffer soln. to give a mixt. of pH 8.5–12.5, whereupon the liberated oil is sepd. from the aq. part. Na_3PO_4, K_3PO_4, borax, $Na_2B_4O_7$ or NH_4OH is specified as buffer substance, dil. alkali metal hydroxide solns. and alkali salts that hydrolyze to form insol. ppts., e. g., Na silicate, being excluded. Free alkali may be present with the alkali salts. App. is described.

Adsorbent material for treating oils and sludges. Henry R. Kraybill, Pearl H. Brewer and Max H. Thornton (to Purdue Research Foundation). U. S. 2,174,177, Sept. 26. A process of prepg. an adsorbent suitable for removing phosphatides, mucilages, sterols, pigments and assocd. substances from vegetable oils and vegetable-oil sludges, refining vegetable oils and reconditioning used mineral oils involves mixing a water soln. of Na silicate with a water soln. of an acid-reacting Al salt, to form a gelatinous ppt., and using solns. of such concn. and keeping the amt. of water present prior to the formation of the gelatinous ppt. sufficiently small that almost but not quite all of it is taken up in the ppt., mixing the ppt. before the mass has time to form a gel with addnl. water in sufficient quantity to prevent the whole from forming a gel on standing, then letting the whole stand, filtering to remove excess water, and drying.

28—SUGAR, STARCH AND GUMS

J. K. DALE

The automatic regulation of temperatures and pressures in the sugar factory. A. Douaze. *Bull. assoc. chim.* **56**, 614–18(1939).—A system for such control is described and illustrated. F. W. Zerban

Residual waters of the sugar industry. Henri Devos. *Sucr. belge* **58**, 169–75, 190–2(1939).—When the solns. from the sugar-beet pulp presses are allowed to pass through a 400-mesh rotary screen and treated with a soln. of lime (0.05 g./l.), losses due to fermentation before and during diffusion are decreased. W. W. Binkley

The possible effect of reducing sugars on the polarization of sugar-beet juices. J. Zamarón. *Bull. assoc. chim.* **56**, 607–13(1939).—Analyses of beets and cossettes have shown that the ratio between direct polarization and actual sucrose is quite variable. For better control the sucrose and the reducing sugars should be detd. The Pb subacetate used for the clarification of beet juices causes errors in the direct polarization, especially with frozen and other beets contg. considerable quantities of reducing sugars. F. W. Zerban

The practicability and advantages derived from accelerating the diffusion. G. Oplatka. *Sucr. belge* **58**, 387–96 (1939); cf. *C. A.* **33**, 5219[1].—Accelerated circulation permitted approx. 50% more juice to pass through the

diffusers and decreased the consumption of carbon and lime. W. W. Binkley

Is high or low temperature necessary during diffusion? The action of heat on fresh sugar-beet pulp. F. Staudinger. *Sucr. belge* **58**, 426–33(1939); cf. *C. A.* **21**, 337.—Rapid heating of sugar-beet pulp in water to 92–5° rendered the pulp more favorable for osmotic diffusion, destroyed undesirable enzymes and microörganisms, aided circulation of the juices, and accelerated diffusion. W. W. Binkley

Heat of solution of sucrose. Philip Lyle. *Intern. Sugar J.* **41**, 390–3(1939).—Certain discrepancies in the heat balance of the refinery were traced to the effects of the heats of soln. and crystn. of sucrose. The existing information on the subject has been reviewed and correlated and the following equation for the calcn. of the heat of soln. at any concn. and temp. has been developed: $Qs, t = \frac{50\,(1 + 2s)}{9\,(9 + s)} - \frac{19\,(258 + t)}{4\,(1000)}$ Qs, t is the heat of soln. of 1 g. of sucrose in sufficient water to give a soln. of concn. s at a temp. $t°$. D. P. Langlois

Fractionation of the chloroform extract of maple sirup. Louis Sair and J. F. Snell. *Can. J. Research* **17**, B, 281–9(1939).—A method of fractionating the $CHCl_3$-sol constituents of maple sirup has been devised. Marked differences were observed among Quebec sirups of different years. Fat constituted half the wt. of the ext. of the 1935 sirup but was completely absent in the 1936, and present in very small quantity in the 1937, product. Crystals of carbonyl compds. having vanillin odor were isolated from bisulfite fractions of the 1935 and 1936 exts., but the crystals from the 2 years' sirups differed from each other in m. p. and chem. behavior. Vanillin was not found. An odorless fraction constituting 35% in 1935 and 65% in 1936 had a compn. and a behavior similar to those of lignin. The substance chiefly responsible for maple odor is indicated to be an enolic viscous oil, volatile at 0.03 mm., and present in the 1936 and 1937 sirups in the proportions of 0.6 g. per 100 gal. of sirup or about 1 p. p. m. J. W. Shipley

Report of the Imperial Agricultural Chemist [on anthocyanin pigments in the rind of sugar canes] (Nath) **15**. Waxy substances of sugar cane (Mitui) **10**. Industrial and agricultural utilization of defecation slime (Spengler) **15**.

Apparatus for making starch suspensions. The Distillers Co. Ltd. and Philip D. Coppock. Brit. 506,501, May 31, 1939. Suspensions of amylaceous materials in H_2O are made by passing a stream of cold H_2O through an injector and inducing the material, in the form of a gelatinized paste, from a receptacle. Valves for controlling the rates of supply are provided and the discharge pipe is furnished with a grid.

29—LEATHER AND GLUE

HENRY B. MERRILL

Rapid method of determining moisture in oak wood extract. M. E. Artamonov. *Kozhevenno-Obuvnaya Prom.* **18**, No. 5, 39–40(1939).—Cut a 5-g. sample of the dry ext. into small pieces, place in a 50-cc. porcelain crucible or beaker, and add 10 cc. of boiling water. Cool to 22°, place in a wooden thermostat, add 5 cc. strong H_2SO_4 (1.8), stir with a glass, and record the temp. rise. The temp. at which the Hg begins to drop is taken as the end of the detn. which lasts 30–40 min. The moisture is equal to $t°K$ where $t°$ is the temp. and K is 0.2045 for oak ext. B. Z. Kamich

Heat resistance of red oak leather at temperatures over 100°. N. I. Egorkin. *Kozhevenno-Obuvnaya Prom.* **18**, No. 3, 21–2(1939).—Effect of temp. on red oak leather was investigated with a lab. press, the specimens being heated to 130° in about 12 min. while some were kept at 50° for periods of 30 min. to 6 hrs. and then heated at 130° after which they were cooled, kept in a desiccator, and subjected to mech. tests. The leather that previously was dried showed no decrease in strength after the press treatment and sometimes even an increase was observed whereas those that were not predried showed a decreased strength. B. Z. Kamich

Leathers for service boots. D. Jordan Lloyd. *Leather World* **31**, 1026–7(1939).—Requirements for different branches of military service are discussed. J. H. H.

Decontamination of leather. D. Jordan Lloyd. *Leather World* **31**, 939–41(1939).—Leather contaminated with mustard gas (blister gas) is reclaimed by soaking 6 hrs. in H_2O at 48, and refinishing. F. O'Flaherty

Rapid method of determining chromium in leather, fur and sheepskin. E. M. Gurevich. *Kozhevenno-Obuvnaya Prom.* **18**, No. 4, 56(1939).—To det. Cr_2O_3 dissolve a 0.20–0.35-g. sample in 5 cc. concd. H_2SO_4 (1.84) and 2 cc. 30% H_2O_2 soln., oxidize with 3% $KMnO_4$, add 0.1 N hyposulfite until the soln. is orange-pink. Filter the soln., destroy the excess $KMnO_4$ with 1–2 drops of hyposulfite and analyze the filtrate iodometrically. B. Z. Kamich

Surface tension and foam formation in glue solutions. E. Sauer and W. Aldinger. *Kolloid-Z.* **88**, 329–40(1939).—The degree of foaming of a series of com. glues (4 from hides and 6 from bone) was detd. by a simple agitation method. The fat content, acid or alkali content, viscosity and pH values were detd. on these glues. The surface tension of the glue solns. was detd. with the Cassel capillarimeter by the method of max. bubble pressure. Neutral fats and free fatty acids greatly reduce the foaming of glue solns. On the addn. of soaps, the degree of hydrolysis of the latter affects the foam formation, the foaming being inhibited to a greater extent by soaps contg. larger amts. of free acid. There is no direct relationship between the foaming properties and surface tension of glues. The decompn. products of glue do not increase its foaming tendency, and have but little effect on its surface tension. The effect of pH on the surface tension is not uniform. The foaming tendency of glue solns. decreases in the alk. range. S. I. Aronovsky

Constitution of natural tannins (Russell, Clark) **10**. Complex metal amine salts [for tanning processes] (U. S. pat. 2,173,823) **10**. Dyeing, bleaching or other liquid treatments of leather (U. S. pat. 2,174,178) **25**. Condensation products [assistants in the leather industry] (Ger. pat. 676,407) **13**.

Tanning. I. G. Farbenindustrie A.-G. Brit. 508,716, July 5, 1939. See Fr. 832,311 (*C. A.* **33**, 2756[8]).

Purifying tanning extracts such as those produced from chestnut chips. Charles R. Oberfell (to The Mead Corp.). U. S. 2,173,977, Sept. 26. A process of purifying a heated tannin ext. through the addn. of albumin thereto while the formation of lumps of albumin is avoided involves adding the albumin in dil. soln. of low concn. of albumin to the tannin ext. heated to a temp. above the normal coagulating temp. of the albumin, and controlling the addn. of the albumin soln. to secure an intimate and thorough intermixture thereof with the heated ext., with resultant coagulation of the albumin and pptn. of the impurities from the ext.

Coating leather. Morris C. Lamb. Brit. 508,369, June 29, 1939. Leather strips or diaphragms, e. g., for governors or gas meters, are protected against deleterious chem. influences by being coated with a finely ground insol. metal oxide made into a paint-like mixt. with an oil or oleaginous agent, e. g., almond, peach-kernel, castor or olive oil or grease. The oxide may be Cr_2O_3, Al_2O_3,

ZnO, MgO or CaO. In an example, Cr_2O_3 prepd. from pptd. $Cr(OH)_3$ is ground with sulfonated oil in a pebble mill before being mixed with the oil.

Apparatus for solidifying liquid gelatin, glue, etc., in films or sheets. Thomas B. Downey. Brit. 508,752, July 5, 1939.

30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

Practical aspects of variations in latex. Five simplified tests. J. W. Malden. *Rubber Age* (London) **20**, 255, 257(1939).—The quality and uniformity of shipments of latex can usually be controlled by 5 tests: (1) dry rubber content, (2) viscosity, (3) color, (4) NH_3 content and (5) stability. Simple reliable procedures for testing these properties are described. C. C. Davis

The specific gravity of rubber in Hevea latex. O. de Vries. *India-Rubber J.* **98**, 422, 424(1939); cf. *C. A.* **29**, 4621[4].—The d. of 0.904 for acid-coagulated rubber from cream with dild. serum obtained by van Gils (*C. A.* **33**, 9041[4]) is unexpectedly higher than the 0.901 value of Rhodes (*J. Rubber Res. Inst. Malaya* **6**, 150(1935)) for acid-coagulated rubber from cream with normal serum. However, both values are open to criticism in 2 respects: (1) the influence of serum substances pptd. by acid; (2) changes which occur during storage, e. g., pptn. of a sludge; and (3) changes caused by NH_3, which are unexplained but which can be detected by changes in the rate of vulcanization and in the viscosity in C_6H_6. The true d. of rubber particles in normal *Hevea* latex is still unknown. A comparison of the chem. compn. of electrodeposited rubber with that of rubber from latex cream should be of aid in correlating d. and chem. compn. of rubber. C. C. Davis

Use of flocks in the rubber industry. II. Flock as a surface coating. M. A. Foley. *Rubber Age* (N. Y.) **46**, 27–8(1939); cf. *C. A.* **33**, 9714[6].—A description of present practice. C. C. Davis

New technique in [rubber] glove testing. R. W. Chadbourn and W. H. Meade, Jr. *Rubber Age* (N. Y.) **46**, 31–3(1939).—Practical expts. show that the use of a high-voltage d. c. gives a more effective, reliable and economical method than does a high-voltage a. c. in searching for imperfections and potential hazards in general. C. C. Davis

Gutta-percha and balata. I. Purification in the factory. H. J. Stern. *Rubber Age* (London) **20**, 245–9 258(1939).—An illustrated description of processes used at the present time. Much of the detailed information on the app. and technique has not been published heretofore. C. C. Davis

Chlorination of Soviet natural and synthetic rubbers. F. F. Koshelev, V. N. Provorov and A. S. Solov'eva. *Caoutchouc and Rubber* (U. S. S. R.) **1939**, No. 8, 21–4, 88.—Chlorination of Soviet natural and synthetic rubbers is best conducted in dichloroethane. All attempts to chlorinate natural rubbers in the absence of a solvent proved fruitless. Chlorination of natural rubbers was accelerated by I, $SbCl_5$ and $AlCl_3$. Chlorination in the presence of I increased the stability of chlorinated rubbers; $AlCl_3$ and $SbCl_5$ increased the percentage of fixed Cl. Chlorination of synthetic rubber in solns. contg. Fe reduced the stability and soly. of the product; Pb decreased the soly. but not the stability of the product. Both Fe and Pb had no effect on the amt. of Cl which combined. Heating the products for 12 hrs. at 60–80° did not reduce their stability. B. Z. Kamich

Finishing fancy and saddle leather substitutes made from synthetic rubber (Slepyan) **13**. Impregnation of textile fibers with latex (Harold) **25**. Synthesis of piperylene from furfural [use in manuf. of synthetic rubber] (Berkenheim, Dankova) **10**. Chlorinated rubber paints and varnishes (Sarx) **26**. Aging phenomena and the mol. size of chain complexes [rubber] in soln. (Wehr) **2**. Decomposition products of synthetic resins [as rubber softeners] (Brit. pat. 507,339) **13**. Synthetic resin compns. [using synthetic rubber] (Brit. pat. 507,501) **13**. Impregnating compns. [by depolymerizing a hydrogenated rubber hydrocarbon] (Brit. pat. 507,855) **13**. Expansion joints [using rubber compns.] (Brit. pat. 507,731) **20**. Treating fibrous materials with aq. dispersions [of rubber] (U. S. pat. 2,173,241) **25**. Rubberizing textiles (Brit. pat. 507,493) **25**. Adhesives [use of rubber latex] (Brit. pat. 507,327) **13**.

Apparatus for forming filaments of rubber from latex. Wm. M. Spencer (to Filatex Corp.). U. S. 2,172,018, Sept. 5. Various structural, mech. and operative details.

Casting rubber articles from latex. Ernst A. Hauser (to "Semperit" Oesterreichisch-Amerikanische Gummiwerke A.-G.). U. S. 2,171,552, Sept. 5. A process of casting rubber articles involves forming a mixt. of a water dispersion of rubber and dead burned gypsum in amount to produce a pourable mixt., thereafter further agglomerating the rubber dispersion by adding an agglomerating agent in amount such as will not immediately substantially reduce the pourability of the mixt., molding the mixt. and vulcanizing.

Coating materials such as paper, cloth or wood, with latex rubber. Gladstone W. Worrall (to Imperial Chemical Industries Ltd.). U. S. 2,170,013, Aug. 22. A process for prepg. an adherent, flexible and nonabsorbent coating comprises coating a base material with a mixt. consisting of rubber latex and Na silicate soln., allowing the coating to dry, treating the same with an acidic insolubilizing agent, applying one or more addnl. coats of a coating material from the class consisting of rubber latex and sheet rubber, and incorporating a wax into the coating.

Manufacture and use of rubber thread. Kenneth R. Shaw (to Easthampton Rubber Thread Co.). U. S. 2,169,886, Aug. 15. See Brit. 494,081 (*C. A.* **33**, 2762[2]).

Treating rubber for use in varnishes, etc. Ernest H. Farmer, Henry P. Stevens and James W. Rowe (to British Rubber Producers' Research Association). U. S. 2,171,395, Aug. 29. A soln. of BF_3 in HOAc is added to a soln. of rubber in an inert org. solvent such as CCl_4 (the HOAc serving as a dehydrating agent) and the mixt. is subjected to boiling.

Forming products such as gloves, from aqueous rubber dispersions. Stephen B. Neiley (to Dewey and Almy Chemical Co.). U. S. 2,172,400, Sept. 12. A dispersion is used contg. a "potential coagulant" such as a Zn NH_4 chloride and a stabilizing excess of a water-sol. amine and after coating a form with this dispersion the excess of amine is exhausted from the coating or treated to cause the "potential coagulant" to become active and coagulate the coating.

Rubber articles such as tire covers. Bernard J. Habgood and Leslie B. Morgan (to Imperial Chemical Industries Ltd.). U. S. 2,170,947, Aug. 29. A process for the manuf. of composite rubber articles and materials comprising vulcanized natural rubber bonded to a vulcanized synthetic rubber-like material made by polymerizing halogen-substituted 1,3-butadiene comprises taking unvulcanized compounded natural rubber and unvulcanized compounded synthetic rubber-like material made by polymerizing halogen-substituted 1,3-butadiene along with an interposed unvulcanized compounded synthetic rubber-like material comprising a halogen deriv. of natural rubber and polymerized 2-chloro 1,3-butadiene, bringing the materials into good contact and then vulcanizing. Numerous examples with details are given.

CHEMICAL ABSTRACTS

Vol. 34 FEBRUARY 10, 1940 No. 3

I--APPARATUS, PLANT EQUIPMENT AND UNIT OPERATIONS

W. L. BADGER

A reflux regulator and head for laboratory rectifying columns. Frederick D. Rossini and Augustus R. Glasgow, Jr. *J. Research Natl. Bur. Standards* **23**, 509–14 (1939) (Research Paper No. 1249). A still head is described embodying a nonlubricated glass valve manipulated through a flexible partition, min. column above long rectifying column, means of obtaining const. and controllable rate of removal of distillate, means of estn. of throughput and rate of removal of distillate, and a thermometer well. Earl H. Brown

Evaporating apparatus with artificial circulation. A. M. Lastovtsev. *Khim. Mashinostroenie* **1938**, No. 2, 5–14; *Khim. Referat. Zhur.* **2**, No. 1, 121(1939). Several evaporators with inner and with outer circulation pumps are described. The coeff. is increased several times (5–6 times in evapg. NaOH, and 6–7 times in evapg. glycerol solns.) as compared with evaporators with natural circulation. The heating surface and the wt. of the app. can be considerably reduced. An evaporator with natural circulation with a heating surface of 450 sq. m. and weighing 28 tons has been replaced by an app. with artificial circulation of the same capacity with a heating surface of 80 sq. m. and weighing 8.7 tons. The saving in first cost amply covers the cost of the circulating pump. Such evaporators are used successfully with very small temp. differences. An 85% glycerol soln. with a η of 25 centipoises was evapd. with a temp. difference of 10–12°. The steam saving amply covers the cost of power for the pumps. The deposition of scale is very small, and no crystals are formed on the heating surface. Liquid contg. up to 20% of solid substances can be evapd. with success. The work of these evaporators is especially effective with solns. with a reversible curve of soly. (sepg. scale as gypsum, Na_2SO_4, sugar molasses, etc.), with those solns. whose soly. increases little on heating and which crystallize considerably on evapn. (NaCl), with viscous solns. (sugar, glycerol), with corroding substances, etc. The manuf. of such app. with artificial circulation offers no difficulties. For the usual evaporator with a heating surface of 10–100 sq. m. a series of propeller pumps with a capacity of 2–20 cu. m./min. and with a pressure of 5–6 m. of water is necessary. W. R. Henn

Nessler cylinders of lead glass. British Standards Institution. *Analyst* **64**, 877(1939).—The difficulty encountered by McLachlan (*C. A.* **33**, 8452[9]) should not arise with Nessler tubes which correspond to British standards, because the maker of the tube is obliged to state that the tubes contain Pb when such is the case. W. T. H.

Effect of foam on entrainment in cap-plate columns. V. N. Stabnikov. *Khim. Mashinostroenie* **8**, No. 6, 17–21 (1939).—The effect of foaming on entrainment was studied with cap-plate columns 200, 300 and 445 mm. high, 232 mm. in diam., and having 2 plates equipped with feed and draw-off pipes, the distances between the plates being 227, 327 and 500 mm. The upper plate contained water and the lower plate, through which air was blown, contained 1 *N* NaOH or 1 *N* NaOH + soap soln. The air speeds were 0.054–0.360 m./sec. Up to an air speed of 0.25 m./sec. the entrainment of foaming liquids was greater than for nonfoaming ones, but at higher speeds the reverse was true. The carry-off of foam also started at speeds higher than 0.25 m./sec. The results are given in tables and graphs. B. Z. Kamich

Constant-level still for redistillation of water. D. A. Wilson and H. S. Strickler. *Ind. Eng. Chem., Anal. Ed.* **11**, 636(1939). An all-glass still is described permitting continuous redistn. of H_2O. H. A. Frediani

Semimicro Kjeldahl distillation apparatus. C. E. Redemann. *Ind. Eng. Chem., Anal. Ed.* **11**, 635–6 (1939).—A 100-ml. Pyrex Kjeldahl flask assembly is described that permits rapid cleaning, prevents liberation of NH_3 until the app. has been swept with steam and is suitably trapped to prevent sucking back of standard acid. H. A. Frediani

Electromagnetic separator for mineral powders. R. C. Evans. *Mineralog. Mag.* **25**, 471–8(1939).—The special points of the app., which is described and figured and in principle resembles that of Hallimond (*C. A.* **25**, 3203), are its robustness, ease of cleaning and freedom from trouble connected with the elec. contacts. It will run automatically for hrs. on end when large quantities of material have to be treated. C. A. Silberrad

Apparatus for determining the melting curve of a small quantity of material. W. M. Smit. *Chem. Weekblad* **36**, 750–2(1939).—The principle of the app. is to heat the sample slowly by maintaining a const. difference of temp. between the sample and its surroundings. The app. is suitable for checking the purity of org. materials. It operates with a sample of 200 to 300 mg. and in a temp. range of 0 to 300°. The melting curves (the temp. of the material plotted as a function of the time) are reproducible to within 3%. N. Bekkedahl

Construction of manometers for measuring flow. A. D. Loring. *Ind. Eng. Chem., Anal. Ed.* **11**, 626–8(1939). Modifications of U-tube principle manometers permitting direct reading are described. H. A. Frediani

Pressure regulator for dynamic gaseous systems. Johannes H. Bruun. *Ind. Eng. Chem., Anal. Ed.* **11**, 628 (1939).—A glass capillary into which a brass, Pt or glass wire can be inserted for varying depths is sealed in series with the gas outlet, the frictional resistance in the capillary controlling the pressure (higher than atm.) in the reaction system. H. A. Frediani

Apparatus for constant-temperature control. R. Tiollais and A. Pédron. *Ann. chim. anal. chim. appl.* **21**, 285–9(1939).—The set-up as described will keep the temp. const. within 0.01° in the range 20–120°. As in other types, the heating is accomplished electrically and the making and breaking of the circuit governing the auxiliary heating are accomplished by the contraction and expansion of a column of Hg. W. T. H.

An improved method of calculation of drying time. J. C. Brier. *Trans. Am. Inst. Chem. Engrs.* **35**, 797–800 (1939).—This paper presents a simplified calcn. of the time required for drying solids under const. condition and shows that a logarithmic mean drying rate can be applied to the falling-rate period of drying, if the drying-rate curve is a straight line. Application of the method to that portion of the drying cycle in which the rate curve is not a straight line is discussed. C. L. Mantell

The importance of the atmosphere in industrial furnaces. R. Martin. *J. usines gaz* **63**, 389–403(1939).—A review of modern developments in heat-treating furnaces in which specified atms. are maintained. B. J. C. v. d. H.

Biophysical problems of air conditioning. C. P. Mom. *Chem. Weekblad* **36**, 717–22(1939). Felix Saunders

The construction of an inexpensive power washer and

designing of economical brushes for the cleaning of laboratory glassware. Harry E. Morton. *J. Lab. Clin. Med.* 25, 211–15(1939).—An app. is described that saves much time in the cleaning process and reduces glass breakage. Howard W. Robinson

Porous rubber for filter sheets (U. S. pat. 2,175,708) 30.

Continuous rotary filter suitable for oils, etc. Henry M. Hunter (to Goslin-Birmingham Mfg. Co.). U. S. 2,174,748, Oct. 3. Various structural and operative details.

Receptacle with a filtering bag suitable for filtering various liquids. Le Roy O. Brown (to Justrite Mfg. Co.). U. S. 2,175,714, Oct. 10. Various structural details.

Spring take-up for glass-fiber air and gas filter units, etc. Jan S. Irvine (to Owens-Corning Fiberglas Corp.). U. S. 2,175,195, Oct. 10. Various structural details.

Container for pouring out measured portions of contained liquids such as lubricating oil. Fred R. Walrod. U. S. 2,175,933, Oct. 10. Various details of a can or the like with a valved measuring compartment.

Adsorber for recovery of solvent vapors from their mixtures with air. Leonard A. Logan (to Carbide and Carbon Chemicals Corp.). U. S. 2,174,666, Oct. 3. Various structural details of an app. suitable for use of granular activated carbon.

Apparatus for agitating bottles containing liquids to mix their contents. Henry J. Chilton (to Liquid Carbonic Corp.). U. S. 2,174,256, Sept. 26. Various structural, mech. and operative details.

Sealing plugs for ampoules, bottles or the like. Conrad Hofmann and Alex Kneip (to Winthrop Chemical Co.). U. S. 2,174,855, Oct. 3. Within the neck of a container such as an ampoule, a sealing ball or the like is provided, which may be formed of alloys such as "Wood's metal" or "Rose metal" or their alloys with Hg 5–10% (supported by wadding or glass wool if desired); or sealing may be effected with water glass cements, cements of Pb oxide and glycerol or fused resins.

Sealing minute openings in pressure vessels such as those of impact arresters or vapor motors. John S. Baker (to Cook Elec. Co.). U. S. 2,175,373, Oct. 10. There is injected into the vessel a liquid which will form a solidified mass when exposed to the atm., and a gas is also injected which will not cause solidification of the liquid, and the liquid is caused to flow over the inner surface of the vessel while under the action of the gas, to fill any pores with solid material.

Centrifugal separator suitable for separating solids from liquids. Mikael Vogel-Jorgensen (to F. L. Smidth & Co.). U. S. 2,174,857, Oct. 3. Various structural details.

Classifying finely divided solids such as ore constituents in liquid suspension. Arthur C. Daman (to Mining Process and Patent Co.). U. S. 2,174,553, Oct. 3. Various details of app. and operation.

Ball mills for wet or dry grinding of coal, limestone, cement clinker, etc. Harry R. Collins. U. S. 2,174,933–4, Oct. 3. Various structural, mech. and operative details.

Rotary-drum mill for pulverizing and classifying various materials, with use of air under pressure. Harlowe Hardinge (to Hardinge Co., Inc.). U. S. 2,174,630, Oct. 3. Various structural and operative details.

Rectangular bell-type furnace suitable for annealing. Frederick R. J. Davis (to Westinghouse Elec. & Mfg. Co.). U. S. 2,175,829, Oct. 10. Various details of hood construction.

Protecting furnace walls. John N. Pyster and Carl W. Stuke. U. S. 2,174,597, Oct. 3. For increasing the life of a furnace wall, its inner face is provided with a thin coating of a metal such as Al, the oxide of which is highly refractory.

Coating interior surfaces of smelting furnaces. John A. Heskett. U. S. 2,175,291, Oct. 10. See Brit. 492,860 (*C. A.* **33**, 2000⁷).

Apparatus such as that with headers and tubes for heat exchange. Hugh Rodman (to Universal Oil Products Co.). U. S. 2,175,412, Oct. 10. In an app. such as one with tube headers, return bends, etc., having a port for the reception of a tubular member and a circumferential groove in the metal walls of the port into which metal of the walls of the tubular member is forced, there is provided a resilient gasket, which may be formed of asbestos and disposed within the groove so that it may be compressed by expansion of the tube walls and prevent leakage.

Heat conversions such as those in thermal pumps Vannevar Bush and Edwin L. Rose (to Research Corp.). U. S. 2,175,376, Oct. 10. Various details of structure and operation of an app. with a regenerator.

Clock suitable for the control of heating or other apparatus. John B. Schroeder (to John W. Silbaugh). U. S. 2,174,331, Sept. 26. Various structural, elec. and operative details.

Refrigerating apparatus suitable for use with mercury and aqueous liquids. Lyman F. Whitney (to Stator Corp.). U. S. 2,174,301, Sept. 26. Various details of an app. having a cooler with walls of metal such as a stainless steel which do not cause the formation of sludge when in contact with the Hg and refrigerant. U. S. 2,174,302–3 also relate to various details of refrigerating and water-heating app.

2– GENERAL AND PHYSICAL CHEMISTRY

FREDERICK L. BROWNE

John Jacob Abel, 1857–1938. Anon. *J. Pharmacol.* **67**, 373–406(1939).—Biography and list of works. L. E. Gilson

Waldemar Lindgren. L. C. Graton. *Econ. Geol.* **34**, 850a–850f(1939).—Obituary, with portrait. Michael Fleischer

The twentieth anniversary of the death of Emile Forcault. J. M. Muhleg. *Glastech. Ber.* **17**, 285–6(1939). J. F. Hyde

What preceded the discovery of the daguerreotype. K. Pejml. *Chem. Listy* **33**, 335–7(1939).—P. reviews the work of the alchemists and the contributions of Scheele, Charles, Senebier, Wedgewood, Davy, Niepce and Herschel to the discovery of the daguerreotype. F. M.

The atomic weight of iron. O. Hönigschmid and Chuan Liang Shu. *Z. anorg. allgem. Chem.* **241**, 361–71(1939).—The at. wt. of Fe was detd. as 55.850 as the av. of 18 analyses of $FeBr_2$ synthesized from its pure components and compared with Ag and AgBr. L. P. Hall

Determination of atomic distances from optical refraction. I. A simple relation of ionic refraction, ionic radius and atomic number of the elements. Ernst Kordes. *Z. physik. Chem.* **B44**, 249–60(1939); cf. *C. A.* **33**, 4131⁷. —The Born repulsion exponent was detd. empirically and used to calc. univalent ionic radii for all of the elements. These results were then used in K.'s empirical relation to obtain ionic refractions which were compared where possible with those calcd. by other methods. II. *Ibid.* 327–43.—The same relation gives good results in the calcn. of at. distances in compds. If both the ionic distance and the mol. refraction are known, the radius and refraction of single ions can be calcd. G. M. Murphy

Magnetic anisotropy of nickel at 20°K. H. J. Williams and R. M. Bozorth. *Phys. Rev.* **56**, 837(1939).—The magnetic anisotropy of Ni was measured at 20 and at 77°K. The formula of Brukhatov and Kirensky (*C. A.* **32**, 2797⁶), based on measurements from 77 to 350°K., is valid to 20°K.: the exptl. data of Honda, Masumoto and Shirakawa at this temp. (*Sci. Repts. Tohoku Imp. Univ.*, First Ser. **24**, 391(1935)) is erroneous. G. M. Petty

Measurement of dielectric loss and high-frequency conductivity. VII. H. Schwindt. *Z. physik. Chem.*

B44, 344–50(1939); cf. *C. A.* **32**, 6518⁴.—It is shown how the previous app. can be used for measurements on liquids of high dielec. const. The energy loss in the comparison condenser is discussed and a method of measuring this quantity is described. Measurements on liquid condensers in which the resistance of the elec. leads cannot be neglected are also discussed. VIII. P. Wulff and H. Schwindt. *Ibid.* 351–8.—The construction of a distn. app. and a quartz condenser for hygroscopic liquids is described. Measurements on benzene-EtOH mixts. were made and the effect of water on the results is discussed. G. M. Murphy

The dielectric constants of polar liquids. J. Norton Wilson. *Chem. Rev.* **25**, 377–406(1939).—If Onsager's theory (*C. A.* **30**, 7002⁷) of liquid dielectrics is modified to include the effect of optical anisotropy, the deviations of the modified theory from agreement with expt. can be consistently correlated with a qual. discussion of the effect of mol. structure on intermol. assocn. in polar liquids. The results indicate that in liquid Et_2O, EtOH and H_2O the mols. are assocd. in such a way that the effective mean square dipole moment is greater than that of a free mol.; in liquid aryl halides and alkyl monohalides, on the other hand, the effective mean square moment is less than that of a free mol. Louise Kelley

Dipole moment of the aminobenzoic acids in dioxane. Lloyd Van Blaricom and E. C. Gilbert. *J. Am. Chem. Soc.* **61**, 3238–9(1939).—Data are given for d_4^{25}, n_D^{25} and η^{25} for 3 concns. of the 3 isomeric $H_2NC_6H_4CO_2H$ in dioxane, from which values of μ are calcd. to be: *o* 1.51, *m* 2.70, *p* 3.51; the values for the Me esters are 1.0, 2.40, 3.30. Although in H_2O the *m*-acid is the only one that is predominantly of the zwitter-ion type, its solns. showing characteristically different behavior from the others, in the nonpolar dioxane it assumes the expected intermediary position between the *o*- and *p*-isomers. C. J. West

Transport phenomena in mixtures of gases. E. J. Hellund and E. A. Uehling. *Phys. Rev.* **56**, 818–35 (1939).—Math. Gregg M. Evans

Relation between viscosity and elasticity of amorphous substances. Adolf Smekal. *Z. physik. Chem.* **B44**, 286–98(1939).—The extension of a relation of Maxwell between viscosity and elastic properties of liquids, which was given recently by Kuhn (cf. *C. A.* **33**, 3225²), and some remarks of S. (*Glastech. Ber.* **16**, 198(1938)) are further generalized. The theory is applied to 6 different silicate glass melts. G. M. Murphy

Some experiments showing the directional reactivities of single crystals of copper. Allan T. Gwathmey and Arthur F. Benton. *Trans. Electrochem. Soc.* **77**, 8 pp. (preprint)(1939).—New expts. were made which show the variations in reactivities of surfaces prepd. parallel to the different crystal planes of a single crystal of Cu. A striking etch-pattern was obtained when a single crystal in the form of a sphere was immersed in Hg for 4 hrs. and the Hg evapd. from the surface by heating in a vacuum. The influence of dissolved gases such as O, H and CO_2 on the etch-patterns produced by the corrosion of Cu by liquids was investigated. The variations in reactivity of surfaces parallel to the different crystal planes are shown to be of importance in the problem of corrosion. The effects of variations in c. d., concn., and nature of the electrolyte on the patterns obtained when a single crystal was electrolytically etched were studied. Quant. measurements were made of the different rates of electrolytic etching of surfaces parallel to the different crystal planes. C. G. F.

Evaporation process of aluminizing optical surfaces. Fred L. McMillan and Wm. M. Craig. *Proc. Okla. Acad. Sci.* **19**, 131–2(1939).—A vacuum chamber is described in which Al can be vaporized from a W filament and condensed on optical surfaces. W. F. Bradley

The effect of intense sound waves on metallic melts. II. The significance of frequency and intensity of the sound waves on the diminution of grain size. Gerhard Schmid and Albert Roll. *Z. Elektrochem.* **45**, 769–75 (1939); cf. *C. A.* **31**, 7315⁹.—The effect was studied of sonic and ultrasonic waves, of frequency 50, 9,000 and 284,000 cycles per sec. and intensity from 1 to 40 w./sq. cm., on the crystn. of Bi alloys of low m. p., e. g., Wood's metal. The diminution of grain size is readily studied by observations of the shortening of the needle-like crystals. The more intense the waves the smaller the crystals; frequency appears to play only a secondary part. It is concluded that the sonic waves do not affect crystn. directly; they break up the larger crystals which would normally be obtained. Calcns. based on the Stokes-Oseen equation are in harmony with the view that the decrease of crystal size is related to the frictional force between the melt and solid. S. Glasstone

Hole theory of diffusion. R. P. Johnson. *Phys. Rev.* **56**, 814–18(1939).—The movement of solute-hole mols. rather than movement of holes alone, is preferred as an explanation of diffusion in metallic solns. G. M. E.

Addition to our work: "The structure of solid hydrogen fluoride." Paul Günther and Kurt Holm. *Z. physik. Chem.* **B44**, 474(1939); cf. *C. A.* **33**, 8073⁶.—Fredenhagen (*C. A.* **28**, 4646⁸), from measurements of vapor d. of HF, concluded that the dissocn. isotherms could be explained only by the presence of a series of different mol. compds., prior to the work of Bauer, Beach and Simons (*C. A.* **33**, 1559⁹). G. M. Murphy

Structure of ferromagnetic ferric oxides, γ-Fe_2O_3. R. Hafl and Th. Schoon. *Z. physik. Chem.* **B44**, 216–26 (1939); cf. *C. A.* **34**, 298⁶.—X-ray studies of γ-Fe_2O_3 prepd. from Fe_3O_4, from an iron arc and from $Fe(CO)_5$ resulted in the values, $a_0 = 8.316 \pm 0.004$, 8.333 ± 0.004 and 8.3 A., resp. No essential difference was found in lattice const. or intensity distribution in the 3 samples. Both x-ray and electron-diffraction powder diagrams showed new interference patterns. They can be explained on the assumption of lower symmetry or a larger elementary cell. Similar results were found in Al_2O_3. G. M. Murphy

Calorimetric study of physical and activated adsorption of hydrogen on nickel. A. Eucken and W. Hunsmann. *Z. physik. Chem.* **B44**, 163–84(1939).—The heat of adsorption of H_2 on Ni was studied calorimetrically between 20 and 273°K. Desorption was also measured in the same temp. range with a hot-wire manometer. Two heats of activation for desorption were detected. One corresponds to 14% of the adsorbing centers and amounts to 9–10 kg.-cal. per mole; the other accounting for the remaining 86% is 18–22 kg.-cal. per mole. The heat of adsorption increases linearly from 4 to 21 kg.-cal. per mole. The van der Waals heat of adsorption is about 800 cal. per mole and depends strongly on the density of coverage of the surface. Low-temp. tunnel effects could not be detected. G. M. Murphy

Calculations of the adsorption behavior of argon on alkali halide crystals. Wm. J. C. Orr. *Trans. Faraday Soc.* **35**, 1247–65(1939).—Theoretical. There are calcd.: (1) the heats of adsorption and the equil. distances of A atoms at various positions on the surface of KCl and CsI crystals; (2) the variation of the heat of adsorption as a first layer of atoms builds up and as a second layer begins. For A on CsI the total energy of adsorption in a hexagonally close-packed layer is 2877 and 2737 cal., resp., on Cs^+ and I^- surfaces; A on KCl gives a mean value for the heat of adsorption normal to the surface in a hexagonally packed layer of 1412 cal. with a total variation over the 100 plane of 534 cal. in excess of the value for square packing thus to make the hexagonal arrangement the more probable configuration. Victor R. Deitz

The damping of energy in films of surface-active substances. R. N. Ivanov. *Bull. acad. sci. U. R. S. S., Sér. géograph. géophys.* **1938**, No. 1, 29–41; *Khim. Referat. Zhur.* **2**, No. 2, 18–19(1939).—In films of soap soln. stretched between 2 wire rings, the equil. force (composed of the force of elasticity φ and the force of resistance f_0) depends on the mech. properties of the film (η, elasticity, etc.). The force of resistance is supposedly proportional to the velocity of the displacement of the ring $yf_0 = \alpha y_1$. In this equation the value of the "damping const." α dets. the damping properties of the given film. In order to verify these conclusions an app. was constructed by means of which the value of the power w_0 of a unit of the surface

film during a complete cycle of vibrations can be measured. During slow and reversible vibrations w_0 is the work done against the force of resistance only, i. e., $w_0 = f_0 v_0$. Thus the previous supposition that $f_0 = \alpha_0 v_0$ is verified. The const. α_0 was measured for a no. of soaps and oils. Numerically in all cases it was close to the "damping const." α. The expts. also showed a large effect of the specific chem. properties of the films on their damping properties. Thus, α for the investigated substances varies from several hundreds (for oils, K laurate) to 6.37 (for K palmitate).
W. R. Henn

Capillary systems. XIX. (9). **The specific permeability and the void structure of packed spheres and of spheres and grains poured together.** Erich Manegold and Karl Solf. *Kolloid-Z.* **89**, 36–47(1939); cf. *C. A.* **32**, 4855⁴.—The av. and free cross section and length of the voids in different modes of packing of spheres of uniform size are calcd. Formulas are then derived for the sp. permeability of these modes of packing, in which there appear only the square of the radius of the spheres and a const. characteristic of the structure. The formulas were tested experimentally for spheres and grains poured together and used to calc. an equiv. radius. The equiv. radius calcd. for poured spheres agrees well with the radius calcd. according to Bjerrum and Manegold (cf. *C. A.* '22, 11) for canal-like void systems with unoriented pore structure. Poured sand exhibits a different behavior: at times the agreement of the 2 pore radii is poor, at other times satisfactory. The radii calcd. according to B. and M. are considered the more reliable. Finally a general filtration equation is calcd. that can be used in many special cases.
F. L. Browne

General chemistry of colloid-colloid reactions. VII. Highly purified protected Sb_2S_3 sols. Wo. Pauli and H. Zentner. *Trans. Faraday Soc.* **35**, 1234–9(1939); cf. *C. A.* **32**, 2809⁶.—Electrodecantation of a mixt. of a highly purified dextrin sol and a highly purified Sb_2S_3 sol gives, after repeated replacements of the top layer with cond. water, a dextrin-free top layer. The small amt. of dextrin remaining fixed on the sol particles is sufficient to preserve the initial protective power. The surface of the particles of the purified protected sol has the electrochem. constitution of the pure Sb_2S_3 sol, but the charge is reduced to half.
Victor R. Deitz

Entropy of mixing for systems with long-chain compounds and its statistical explanation. Kurt H. Meyer. *Z. physik. Chem.* **B44**, 383–91(1939).—The entropy of mixing of a liquid and a chain polymer is greater than the ideal entropy of mixing.
G. M. Murphy

Polarimetric study of the effect of temperature on aqueous solutions of *l*-malic acid. R. Descamps. *Bull. soc. chim. Belg.* **48**, 293–314(1939).—The expts. at 75° previously described (*C. A.* **33**, 9093⁴) are extended to the temps. 20°, 45°, 55° and 95°. For concd. aq. solns. increasing temp. accelerates the establishment of the equil. *l*-malic acid ⇄ active dehydration products + water and displaces the equil. toward the formation of dehydration products. The reversibility is demonstrated by the fact that the $(\alpha)^{20}_{\lambda 61}$ of a soln. decreases on heating at 75° because of the formation of active dehydration products and increases on further heating at 45°. In some cases on prolonged heating fumaric acid crystallizes out and the products depend on the duration of heating as well as on temp. If concd. solns. heated for 161 hrs. at various temps. between 45° and 109° are converted to 7.7 g. per 100 g. soln., examn. of the rotatory power of these secondary solns. indicates that the primary solns. undergo modifications whose nature depends on the temp. Since the rotatory power of aq. solns. of *l*-malic acid develops spontaneously at all temps. and even at ordinary temp. at least in concd. solns. it is necessary to read the polarimetric points as soon as possible after soln. especially in concd. solns. and at high temps.
Janet E. Austin

Inulin and its molecular weight. S. Bezzi. *Atti X° congr. intern. chim.* **3**, 39–46(1939).—From 25 g. com. inulin (I) (0.13% ash) purified by the somewhat modified method of Irvine and Steele (cf. *C. A.* **16**, 2850) was obtained 15 g. I (0.01% ash, $[\alpha]_D^{19}$ −34.45°) with no reducing power for Fehling's soln. Cryoscopic measurements were made in H_2O with a thermometer accurate to 0.002° and a const.-temp. bath (±0.02°). Osmotic pressures of I in H_2O were measured at 20° with a modified Ulmann method with a temp. maintained const. to within ±0.001°. Viscosity was detd. also by use of the capillary viscometer of Ostwald. F.-p. measurements, which gave a mol. wt. of 3764, were not considered very reliable for polymers. This value is about one-half that (7777) obtained by the second method, the latter being in accord with the value of Haworth and collaborators using a chem. method. From viscosity results it is believed that the mol. of I in soln. has a thread-like or straight-chain shape rather than a spherical one, which fact precludes application of the dialysis method because the former type of mol. gives exaggerated mol. wts. by this method (cf. Staudinger and Lohmann, *C. A.* **30**, 4379⁹; Herzog and Kudar, *C. A.* **28**, 2243⁹; H., *C. A.* **29**, 3576⁹).
J. C. Lo Cicero

Remarks on the work of G. V. Schulz on the osmotic pressure and the state of the solvent in the system acetone - nitrocellulose. Ch. G. Boissonnas and Kurt H. Meyer. *Z. physik. Chem.* **B44**, 392–6(1939).—The osmotic pressure measurements of S. (cf. *C. A.* **33**, 5265⁶) are erroneous and unsuitable for calcn. of heats and entropies of dilu.
G. M. Murphy

Activity coefficients of some alkali halides at 25°. R. A. Robinson. *Trans. Faraday Soc.* **35**, 1217–20(1939). A set of activity coeffs. of KCl for isopiestic data at 25° is assumed which agree with the e. m. f. detns. of Harned and Cook (*C. A.* **33**, 3663¹) and of Shedlovsky and MacInnes (*C. A.* **31**, 3764⁴). The isopiestic data then give a set of activity coeffs. for NaCl agreeing with the values of Harned and Cook; similarly for NaBr and KBr. The plot of the isopiestic ratio (m_{KCl}/m_{NaCl} of equal vapor pressure) against m_{NaCl} between 1 *M* and 4 *M* at 25° agrees with the equation: $m_{KCl}/m_{NaCl} = 1.0082 + 0.03237\, m_{NaCl}$.
Victor R. Deitz

Relative osmotic coefficients of sodium and potassium chloride in deuterium oxide at 25°. R. A. Robinson. *Trans. Faraday Soc.* **35**, 1220–2(1939). Data are presented in the concn. range 0.5 to 4 *M* giving the molalities of KCl and of NaCl (mols. per 1000 g. D_2O) that are isopiestic. A plot of the isopiestic ratios against the molality of NaCl shows that the ratio is considerably higher in D_2O (99.6% purity) than in H_2O at the same molality, the difference increasing with increasing salt concn.; e. g., at 3 *M* NaCl the isopiestic ratio is 1.105 in H_2O and 1.122 in D_2O. When correction is made for the 10% difference in mol. wt. of the solvents by expressing the concns. in mol. ratios of salt to solvent, a much smaller difference remains at corresponding mol. ratios. A difference of 0.5% in these osmotic ratios exists at the highest concns.
Victor R. Deitz

Heat content and heat capacity of sodium chloride solutions. R. A. Robinson. *Trans. Faraday Soc.* **35**, 1222–8(1939).—The isopiestic ratio of KCl and NaCl was detd. over the concn. range 0.1 to 4 *M* NaCl at 5° intervals between 15° and 60°. The results valid above 1 *M* NaCl are given by: $m_{KCl}/m_{NaCl} = 1.00633 + 0.00019(t - 15) + (0.03337 - 0.0001(t - 15))m_{NaCl}$. Below 1 *M* NaCl there is a temp. coeff. of $0.0001 m_{NaCl}$ per degree. The results agree with the e. m. f. detns. of Harned and Nims (*C. A.* **26**, 1500; **33**, 3663⁴) and the b.-p. detns. of Smith (*C. A.* **33**, 5727⁸). From the activity coeffs. there are calcd. the partial molal heat content of NaCl in terms of the heat content at 25°, the partial molal heat capacity, and its temp. coeff. For NaCl good agreement is obtained with the direct calorimetric measurements of the partial molal heat content.
Victor R. Deitz

Activity coefficients of sulfuric acid and lanthanum chloride in aqueous solution at 25°. R. A. Robinson. *Trans. Faraday Soc.* **35**, 1229–33(1939).—The activity coeffs. of H_2SO_4 solns. were detd. by the isopiestic method at 25° between 0.2 and 3 *M*; that of $LaCl_3$ between 0.2 and 1.5 *M* with addnl. data from e. m. f. of cells with transport. The results agree well with e. m. f. and direct vapor-pressure detns.
Victor R. Deitz

Strong and weak dipole formers. K. L. Wolf and H.

Harms. *Z. physik. Chem.* **B44**, 359–73(1939).—Non-electrolytes can be divided into 2 classes corresponding to strong and weak electrolytes. They can be distinguished by the concn. dependence of the orientation polarization and the mol. wt. as well as a few other properties of the soln. in ion-free and dipole-free liquids. G. M. M.

Kinetics of chain polymerization. VIII. Branching reactions. G. V. Schulz. *Z. physik. Chem.* **B44**, 227–47 (1939); cf. *C. A.* **33**, 9104[3].—From various expts., it is concluded that the polysterene mols. are branched. The degree of branching increases with the polymerization temp. The mol. is characterized by a principal axis, from which shorter side branches grow. Branching and netting processes are distinguished and it is shown that insol. products are obtained in general in the latter reaction while sol. products are obtained in pure branching reactions. The statistical distribution of the mol. wt. may be described for branching reactions by the same function that is used for normal polymerization reactions. G. M. Murphy

Kinetics of the decomposition of hydrogen peroxide by means of gold sols of different degrees of dispersion. I. S. Teletov and N. A. Braunshtein. *Trudy Inst. Khem. Khar'kov. Derzhavn. Univ.* **3**, 7–13(1938); *Khim. Referat. Zhur.* **2**, No. 2, 4(1939).—The sols of Au used in the investigations were prepd. by reduction of $AuCl_3$ with alc., ether soln. and tannin, and by interaction between $AuCl_3$ and H_2O_2. The sols were dialyzed for 2–3 days and were examd. in a tyndallmeter and in a colorimeter. In a neutral medium none of the sols decompd. H_2O_2. The catalytic decompn. takes place only in the presence of NaOH (as was detd. previously by Bredig and Reinders for the sol obtained by the electrolytic method). The velocity of decompn. of H_2O_2 was max. in $N/32$ NaOH. The velocity const. (calcd. from the equation of the first order) has different values for sols obtained by different methods. The catalytic decompn. of H_2O_2 by sols of the same concn. increases with the increase of their dispersion. W. R. Henn

Preparation of colloidal rhenium and its catalytic properties. C. Zenghelis and Catherine Stathis. *Compt. rend.* **209**, 797–9(1939); cf. *C. A.* **33**, 8081[2].—A more active, though less so than that of Rh (*C. A.* **32**, 4060[6]), colloidal soln. of Re, stable for several months, is prepd. by dissolving 1 g. K_2ReCl_6 in 10 cc. H_2O, adding 100 g. soln. of gum arabic, followed by 66 cc. 1% hydrazine. The mixt. is heated to 45–50° and 3 cc. of 35% formaldehyde dropped in and the whole heated for 30 min., dialyzed and concd. to 100 cc. at 40–45°. Such a soln. absorbs H_2, accelerates decompn. of H_2O_2, causes formation of NH_3 from its elements, and hydrogenation of maleic or cinnamic acids. The Re appears to be present as metal and not as suboxide. C. A. Silberrad

The copper-manganese system. G. Grube, E. Oestreicher and O. Winkler. *Z. Elektrochem.* **45**, 776–84 (1939).—The data obtained from thermal analysis, elec. cond., hardness, microscopic and x-ray studies are used to draw the complete phase diagram for the Cu-Mn system. The first solids to sep. from the melts are solid solns. contg. either 0–75.5% γ-Mn or 75.5–100% δ-Mn. The solidus and liquidus curves have a min. at 871° and 36.5% Mn. On cooling the δ-solid solns. decomp. at the peritectic point (1113°) forming γ-solid solns. The $\beta \rightleftarrows \gamma$ and $\gamma \rightleftarrows \delta$ transition points of Mn are lowered by Cu, but the $\alpha \rightleftarrows \beta$ transition temp. at 750° is unaffected. The results differ to some extent from those previously described by Pommer (cf. *C. A.* **24**, 5703). S. Glasstone

The structure of the γ-solid solutions in the palladium manganese system: a correction. G. Grube and O. Winkler. *Z. Elektrochem.* **45**, 784–7(1939); cf. *C. A.* **31**, 934[6], 938[6].—The γ solid solns. obtained between 1070° and 1160° were reinvestigated by means of x-rays. The tetragonal face-centered γ-form of Mn, which according to previous workers was supposed to be stable between 1191° and the m. p., is identical with the γ-form existing between 1070° and 1160°. Between the latter temp. and the m. p. the δ-form of Mn is stable. S. Glasstone

Phase equilibria in hydrocarbon systems. The methane ethane system in the gaseous region. B. H. Sage and W. N. Lacey. *Ind. Eng. Chem.* **31**, 1497–1509 (1939); cf. *C. A.* **33**, 30[4].—The sp. vol. of 5 gaseous mixts. of methane and ethane was detd. at 6 temps. between 70° and 250°F. and at pressures up to 4750 lb. per sq. in. The results are presented in tabular form. The partial volumetric behavior of methane and ethane in this system was calcd. From these data, together with other pertinent published information, the partial thermodynamic behavior of these components was calcd. throughout the above-mentioned ranges of pressure and temp. The fugacity, partial vol., and partial enthalpy of methane and ethane are presented in graphical and tabular form. F. L. Browne

5—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

A. B. F. DUNCAN

The mesotron. Giovanni Gentile. *Scientia* **66**, 165–75 (1939).—A nonmath. discussion. L. E. Gilson

Deviation from the Coulomb law for a proton. H. Frohlich, W. Heitler and B. Kahn. *Phys. Rev.* **56**, 961–2 (1939); cf. *C. A.* **33**, 6135[4].—Reply to Lamb, *C. A.* **33**, 8101[5]. G. M. Petty

The equality of the proton-proton and proton-neutron interactions. Frederick W. Brown and Milton S. Plesset. *Phys. Rev.* **56**, 841–2(1939).—It is shown that either (1) the ranges of the ^1S and ^3S neutron-proton interactions are unequal, or (2) the ^1S proton-proton interaction does not equal the ^1S proton-neutron interaction. G. M. Petty

Analysis of proton-proton scattering data. E. Creutz. *Phys. Rev.* **56**, 893–4(1939).—An extension of the analysis of Breit, Thaxton and Eisenbud (cf. *C. A.* **33**, 6135[6]) to include coeffs. for every 50 c. kv. and every $2^1/_2°$ from 15° to 45°, and a fitting of the data of Hafstad, Heydenburg and Tuve (cf. *C. A.* **32**, 3256[9]) in the sense of least squares. Bernard Lewis

Effects of shape of potential energy wells detectable by experiments on proton-proton scattering. L. E. Hoisington, S. S. Share and G. Breit. *Phys. Rev.* **56**, 884–90 (1939).—The shapes of several types of potential wells giving approx. agreement with proton-proton scattering expts. are discussed. The approx. equality of the proton-proton and proton-neutron interactions is discussed, and the close agreement in the case of the meson potential is shown to be due to the large attraction at small distances. Bernard Lewis

The thermionic and adsorptive properties of the surfaces of a tungsten single crystal. S. T. Martin. *Phys. Rev.* **56**, 947–59(1939).—The thermionic emission from a spherical W single crystal has been observed. Photographs and diagrams show qualitatively the dependence of this emission on crystallographic direction. Nearly all the max. and min. lie on a 110 zone. Similar observations have been made on the same crystal when Cs and Ba were adsorbed thereon. Adsorption forces are largest for Cs on surfaces of highest work function. For Ba the adsorption forces appear to be more dependent on surface structure, as the force between the ion and its image contributes the major part of the adsorption energy. The behavior of adsorption as a function of crystallographic direction is such that the sphere surface may be approximated by that which would be obtained by carving the sphere from a perfect lattice. There is no evidence for a faceted or step-like microstructure. Emission from the spherical crystal when Cs is adsorbing on contaminated complex surfaces is more complicated in its dependence on crystallographic direction than when the surface is clean, and a map of the emission over the crystal changes its configuration with

temp. This behavior is not observed when the surface is clean or only slightly contaminated. Bernard Lewis

Emissive and thermionic characteristics of uranium. W. L. Hole and R. W. Wright. *Phys. Rev.* **56**, 785-7 (1939).—The emissivity below the m. p. is 0.51 (λ = 0.67 μ); the thermionic work function is 3.27 ± 0.05 v., with a Richardson A of about 6; m. p. 1700 ± 25° and the av. coeff. of expansion, 25 1000°, 4 × 10^{-6}. Gregg M. Evans

The scattering of neutrons from the C + D reaction. E. Amaldi, D. Bocciarelli, F. Rasetti and G. C. Trabacchi. *Phys. Rev.* **56**, 881-4(1939).—The scattering cross section for neutrons emitted by bombarding C with 600-e. kv. deuterons was measured for 39 elements. Bernard Lewis

Scattering of photoneutrons from deuterium by the nuclei of atoms of light elements. T. Goloborod'ko and A. I. Leĭpunskiĭ. *Phys. Rev.* **56**, 891 2(1939).—The cross sections for the scattering of photoneutrons of different energies by at. nuclei were investigated. The photoneutrons were derived from deuterium irradiated by γ-rays from Ra-Th. Results are given for 17 elements from H to Ca. Bernard Lewis

The disintegration of mesotrons. Bruno Rossi, H. Van Norman Hilberry and J. Barton Hoag. *Phys. Rev.* **56**, 837 8(1939); cf. *C. A.* **33**, 1208[9].- The absorption of the mesotron component of cosmic radiation was compared in air and in C. The data give definite evidence of mesotron disintegration: their lifetime is 2 × 10^{-6} sec. G. M. Petty

Density distribution and energy spectrum of B-electrons. III. Further studies of the box model. (Cylindrical ring, compression of B-electrons.) Otto Schmidt and Heini Schmidt. *Z. physik. Chem.* **B44**, 185-93(1939); cf. *C. A.* **33**, 4131[9].—The previous calcns. are extended to hydrocarbons, C_nH_n, where n is greater than 6. For benzene, the model is a full cylinder but in the cases studied here it is a cylindrical ring. The boundary conditions required are const. potential within the box, freedom of B-electrons and infinitely high, steep potential barriers. The results are similar to those obtained by Huckel (*C. A.* **26**, 25) with a different model. Eight-membered rings are unstable but 10- and 12-membered rings are stable. The plane mol. $C_{10}H_{10}$ has aromatic character. **IV. Mechanism of the excitation process in cancerous and healthy cells.** Otto Schmidt. *Ibid.* 194 202.- The energy consumption in the mutation theory of tumor formation corresponds to an excitation and is of the order of a few e. v. The lowest energy of activation corresponds with excitation of the loosely bound B-electrons of the C= O double bond of an amino acid group of a protein mol. With this assumption, the racemization results of Kögl and Erxleben (cf. *C. A.* **33**, 9421[4]) can be explained. G. M. Murphy

The color of organic substances. Gilbert N. Lewis and Melvin Calvin. *Chem. Rev.* **25**, 273 328(1939). Absorption of light is due to the excitation of electronic oscillations. In a mol. of the "ideal" type, such as a paraffin, the energy of excitation is high but diminishes as the mol. is strained. A great strain is produced by double bonds, which differ from one another in this regard. Color ordinarily appears in conjugated systems, where the 2 detg. factors are the no. of electrons involved and electron mobility. The mobility is small in a mol. whose properties correspond to a formula in which all electrons are paired and there is no "formal" charge on any atom. When such a structure is the major contributing form of a resonating mol., the mobility is still small. When, however, the actual state of a mol. differs considerably from a classical or an ideal structure, the mobility is greatly increased. In other words, displacement from the ideal structure makes further displacement easier. Strong color is obtained when 2 important resonance forms are such that the change from one to the other involves the movement of an elec. charge. This is a unit charge in many dyes of the ionic type, but there are many neutral dyes in which that part of the mol. in which an oscillation can occur acquires some pos. or neg. charge from the rest of the mol. In such cases any change in the mol. which increases that charge enhances the color of the mol. Louise Kelley

Changes in intensity and composition of cosmic rays with magnetic latitude. P. Auger, R. Grégoire, R. Maze and B. Goldschmidt. *Compt. rend.* **209**, 794-7(1939).—By means of a pair of counters placed vertically above each other, or on the same level 5.4 cm. apart, with 10 cm. of Pb suitably placed variations in the hard and soft components of cosmic radiation were measured on a voyage from Marseilles to Tahiti via Panama. Results show great constancy in the compn. of the radiation as regards the relative proportions of mesotrons and electrons, and support the hypothesis of spontaneous decompn. of the mesotrons. C. A. Silberrad

Electronic energy bands in metallic tungsten. Millard F. Manning and Marvin I. Chodorow. *Phys. Rev.* **56**, 787-98(1939); cf. *C. A.* **32**, 5299.—Curves and contours for the various bands and an equation for the electronic specific heat are given, with discussions of the differences between W and Ta. Gregg M. Evans

Measurements of the mobility of potassium ions at high field intensity and low pressure. Allen V. Hershey. *Phys. Rev.* **56**, 908-15(1939). -The mobility of K ions in the gases H_2, He, N_2 and A was measured by the Townsend method (T. and Tizard, *C. A.* **8**, 2103). Bernard Lewis

A theory for the mobility of ions of high velocity. Allen V. Hershey. *Phys. Rev.* **56**, 916 22(1939). - The theories of Langevin (*Ann. chim. phys.* **8**, 245 (1905)) and of Hasse and Cook (cf. *C. A.* **23**, 5077; **25**, 5833) for the mobility of ions in weak fields have been generalized to fields of any strength. The random energy of the ions is assumed to have a Maxwellian distribution, and the drift and random energies are both evaluated by momentum and energy balances. Bernard Lewis

Search for β- and delayed γ-radiation from the deuteron-deuteron reaction. M. H. Kanner and W. T. Harris. *Phys. Rev.* **56**, 839 40(1939). -If an excited He^3 exists, its lifetime for positron emission is greater than 10 days; for γ-ray emission, greater than 15 min. The possibility of internal conversion or of short-lived positron radioactivity was eliminated G. M. Petty

Low-energy γ-radiation from lithium bombarded with protons. W. A. Fowler and C. C. Lauritsen. *Phys. Rev.* **56**, 841 2(1939); cf. preceding abstr.—The radiation from $Li^7 + H^1$ was investigated as a function of proton energy (0 1.4 m. e. v.). With bombarding proton energies of 1080 and 1290 e. kv., γ-rays of 495 ± 25 e. kv. are emitted. G. M. Petty

Disintegration of beryllium by electrons. Geo. B. Collins, Bernard Waldman and Eugene Guth. *Phys. Rev.* **56**, 876 80(1939); cf. *C. A.* **33**, 2798.—The Be nucleus was disintegrated by fast electrons whose energies exceeded the photoelec. threshold. The electron source was a 1.8-m. e. v. Van de Graaff generator. Neutrons were produced and the radioactivity that these neutrons produced in Ag was used as a measure of the rate of disintegration. The yield curve for disintegration by electrons was obtained, and fixed the threshold for this process at 1.63 ± 0.05 m. e. v. At 1.73 m. e. v. the cross section was found to be 10^{-31} sq. cm., in good agreement with theory. The yield curve for photodisintegration by continuous x-radiation was also obtained, and the threshold was found to be identical with that for disintegration by electrons. Bernard Lewis

Magnetic spectrograph investigation of N^{13} γ-radiation. G. E. Valley. *Phys. Rev.* **56**, 838(1939).—Several authors have reported that the decay of N^{13} is accompanied by a γ-ray of 280 ± 30 e. kv. in addn. to the positron annihilation (Richardson, *C. A.* **32**, 4872[6]; **33**, 6144[6]; Lyman, *Phys. Rev.* **55**, 1123(1939); Watase and Ito, *C. A.* **33**, 8492[5]). In this region there are not more than 0.05 γ-rays per disintegration: at no point from 200 to 325 e. kv. is there more than 0.11 γ-ray per disintegration. G. M. Petty

Pair emission from fluorine bombarded with proton. W. A. Fowler and C. C. Lauritsen. *Phys. Rev.* **56**, 840-

1(1939).—A relative intensity—proton energy (0–1.4 m. e. v.) curve is given for electron pairs from F bombarded with protons. These pairs occur at resonance energies which do not coincide with the γ-ray resonances. The pairs are not produced by internal conversion of γ-rays in the usual sense, but are emitted directly from a nucleus in an excited state. Presumably this is a state in O^{16}; possibly some or all of the pairs observed originated from a transition in Ne^{20}. G. M. Petty

Coincidences between β- and γ-rays in Na^{24}. Lawrence M. Langer, Allan C. G. Mitchell and Paul W. McDaniel. *Phys. Rev.* **56**, 962–3(1939); cf. *C. A.* **33**, 8107[3], 9125[5].—The end of the β-spectrum occurs at 1.43 ± 0.05 m. e. v. There are 3.0 β-γ coincidences per 1000 β-rays from 0 to 1.3 m. e. v.: this means that the β-spectrum of Na^{24} consists of a single group. Furthermore, Mg^{24} is formed in an excited state. The av. no. of γ-rays per disintegration is 2.36. G. M. Petty

Mass and energy levels of S^{33}. Ernest Pollard. *Phys. Rev.* **56**, 961(1939).—S, bombarded by 3.1-m. e. v. deuterons gave proton groups with energy change values of +6.60, +3.70 and +1.02 m. e. v.: $S^{32} + H^2 \rightarrow S^{34} + H^1$. The mass of S^{34} is 32.9818 ± 0.0030. G. M. Petty

The internally converted γ-rays of several radioactive elements. G. E. Valley and R. L. McCreary. *Phys. Rev.* **56**, 863 71(1939).—The conversion electron spectra of a no. of radioactive elements produced by proton and deuteron bombardment in the cyclotron have been investigated. The results are: Br^{80} (4.4 hrs.) 3 conversion lines observed corresponding to 2 γ-rays, one of 48.9 ± 0.4 e. kv. and a second of either 37.1 or 25.3 e. kv., both arising in the isomeric transition to the 18-min. state. Br^{75} (6.3 min., e^+) *K* and L_1 conversions in Se of 2 γ-rays of 45.8 ± 0.4 and 107.7 ± 0.9 e. kv.; $Cd^{107 \text{ or } 109}$ (6.4 hrs., *K* capture) *K*, L_1 and M_1 conversions of a γ-ray of 92.6 ± 0.8 e. kv. In this case there is an anomalously high L_1 conversion since the *K* and L_1 lines have nearly equal intensity. Also a 530-e. kv. γ-ray, possibly annihilation radiation, although no positrons are observed. Ga^{67} (78 hrs., *L* capture) *K* and L_1 conversions of a γ-ray of 92.5 ± 0.8 e. kv.; Ga^{70} (18.5 min., e^- and possibly *K* capture) *K* and L_1 conversions of a γ-ray of 53.8 ± 0.5 e. kv. and probably a second line of about 117 e. kv. Bernard Lewis

Radioactivities produced by proton bombardment of palladium. T. Enns. *Phys. Rev.* **56**, 872-6(1939).—Proton bombardment of Pd produces the 3 known Ag periods of 2.3 min. (Ag^{108}), 25 min. and 8 days (Ag^{106}), and 3 new periods of 16.3 min. (+), 73 min. (+) and 45 days (*K* capture). The latter are assigned tentatively to Ag^{107}, Ag^{104} and Ag^{105}, resp. Excitation functions for the isomeric 25-min. and 8-day periods give *p-n* thresholds of 3.8 and 3.9 m. e. v., resp. The former agrees with the known positron spectrum of the short period. The higher threshold for the 8-day period indicates that this state lies above the 25-min. state. This activity is accompanied by probably 3 γ-rays of which 2 of 0.62 and 1.06 m. e. v. have been identified with a γ-ray spectrograph. Since no positrons accompany this activity it must decay mainly by *K*-electron capture to Pd^{106} rather than to the lower isomeric state. Four γ-rays of about 0.29, 0.42, 0.50 and 0.69 m. e. v. accompany the 45-day period. B. Lewis

Radium content of an ocean-bottom core. C. S. Piggot and W. D. Urry. *J. Wash. Acad. Sci.* **29**, 405–10(1939).—A new sampler has been developed which makes it possible to probe below the ocean-bottom surface and to det. the radioactive relationship between the ocean troughs and the continents. An Atlantic core, 2.85 m. long and extremely uniform in compn. both chemically and lithologically, was exam'd. A Ra content corresponding approx. to that of granite, with no increase with depth, was found. Conclusion: Chem. deposition played no role in the radioactivity of this particular core. M. Farnsworth

The separation tube. I. Principles of a new method of gas and isotope separation by thermal diffusion. K. Clusius and G. Dickel. *Z. physik. Chem.* **B44**, 397–450 (1939); cf. *C. A.* **33**, 4748.—Complete details of the method are given. Preliminary expts. were made with CO_2-H_2 mixts., air and a partial sepn. of the Ne isotopes was obtained. Two lecture demonstrations with Xe-H_2 and Br_2-He mixts., resp., are described. Theoretical conclusions were tested with CO_2-free air. The transport of enriched component in the tube is proportional to the following factors: the sepn. factor at the place of entrance of fresh gas; the time; the square of the pressure; the fourth power of the radius of the tube; the square of the temp. difference for small temp. difference; it is independent of the length of the tube. The end concn. is inversely proportional to the fourth power of the radius of the tube and the square of the pressure and directly proportional to the sepn. factor. Possible applications of the method are, sepn. of azeotropic mixts., purification of gases, detn. of assocn. in gases, sepn. of fogs in gases, sepn. of isosteric and isomeric gas mixts., sepn. of isotopes, sepn. of liquid mixts. **II. Separation of the chlorine isotopes.** *Ibid.* 451 73; cf. *C. A.* **33**, 6148[4].—The method was applied to HCl in a tube of 36 m. length. At.-wt. detns. were made to measure the extent of sepn. The final product of 480 cc. HCl contained 99.6% Cl^{35} with an at. wt. of 34.979 and 635 cc. HCl, contg. 99.4% Cl^{37} of at. wt. 36.956. The energy required per mol. of HCl was 3.7 × 10^{10} cal. and the theoretical efficiency was 9 × 10^{-9}. Comparison is made with other methods of sepg. isotopes. G. M. Murphy

Disorder phenomena in manganese oxides according to the Hahn emanation method. Robert Jagitsch. *Z. physik. Chem.* **B44**, 209–15(1939).—Interaction between solids and gases results in a change of the temp. dependence of the emanation power owing to the probability of formation of nuclei. The dissocn. of MnO_2 into Mn_2O_3 results in the absorption of 25.3 kg.-cal. G. M. M.

The inversion of alkali doublets. Gentaro Araki. *Proc. Phys.-Math. Soc. Japan* **21**, 508–16(1939).—It is shown that if the electromagnetic screening of an at. core is greater than the at. no. the signs of the displacements of levels in the doublet splitting are reversed, resulting in the inversion of the doublet. The effect is greater for a neutral atom than for one that is ionized. A general formula is derived for the doublet levels of the alkalies. Applied to the $4f^2F$ term of Cu I it gives a calcd. doublet interval of −4.0 $cm.^{-1}$ in good agreement with the observed interval of −3.6 $cm.^{-1}$. C. C. Kiess

Spectra of M supergiant stars. Lyman Spitzer, Jr. *Astrophys. J.* **90**, 494 540(1939).—Line widths and central intensities have been measured for some multiplets of Fe I, Mn I, Sc II, V I and Co I in the spectra of the class-M supergiant stars α Orionis and α Herculis. From these data it is found that the at. absorption coeff. is given by the usual radiation-damping formula with a damping const. approx. 500 times greater than the classical value. C. C. Kiess

Physical processes in gaseous nebulae. VIII. The ultraviolet radiation field and electron temperature of an optically thick nebula. Lawrence H. Aller, James G. Baker and Donald H. Menzel. *Astrophys. J.* **90**, 601–10 (1939); cf. *C. A.* **33**, 9135[4].—A numerical example, in which a star radiating as a black body at 80,000° illuminates a nebular shell of optical thickness 3.0 at the limit of the Balmer series of H, is solved to illustrate the use of the formulas given previously (*C. A.* **33**, 6150[8], 9135[4]). C. C. Kiess

Negative ions of hydrogen and the opacity of stellar atmospheres. Rupert Wildt. *Astrophys. J.* **90**, 611–20 (1939).—The effect of neg. H ions in increasing the absorption coeff. of stellar atms. is discussed. For stars of class F5, and later (including the sun), the effect is to remove the discontinuity at the limit of the Balmer series of H, and to confirm Russell's deduction (*C. A.* **28**, 3302[8]) that the abundance ratio of H to metallic vapors in the sun's atm. is of the order 1000:1. C. C. Kiess

The cyanogen discriminant between giant and dwarf stars. Dorrit Hoffleit. *Astrophys. J.* **90**, 621–4(1939).—The presence or absence of the cyanogen band at 4144–84 A. in the spectra of stars of classes *G* and *K*, proposed by Becker as a discriminant for distinguishing giant from

dwarf stars, is confirmed from studies of Harvard observations of stellar spectra. C. C. Kiess

The continuous spectrum of stars with extended atmospheres. D. Barbier and D. Chalonge. *Astrophys. J.* **90**, 627 9(1939).—The presence of a continuous spectrum at the limit of the Balmer series of H in a star's spectrum is an indicator of an extended envelope in which H is as conspicuously present as in the photosphere. C. C. Kiess

Interstellar calcium and color excess. Jesse L. Greenbaum and Otto Struve. *Astrophys. J.* **90**, 625–6(1939).—The star HD 147889 shows only a trace of the *K* line of Ca II in its spectrum although it is situated in very dense dark nebulosity and has a color excess of +1.8 magnitude. These facts illustrate the nondependence of the intensity of the interstellar Ca lines on the amt. of interstellar reddening. C. C. Kiess

Note on the interstellar band at λ 4430. Frances Sherman. *Astrophys. J.* **90**, 630 2(1939).—The interstellar absorption line at 4430 A., as yet of unknown chem. origin, appears with highest intensity in stars that appear reddened by the absorption of interstellar matter. C. C. Kiess

Discontinuous molecular spectra. II. Rudolf Frerichs. *Physik regelmassig. Ber.* **7**, 153 67(1939). - A discussion of advance in the exptl. study of spectra, quant. spectral analyses, rotation spectra, rotation-vibration bands, isotope effects of the band spectra, hyperfine structure and the nuclear spin in band spectra, predissocn., diffused bands, Zeeman and Stark effects of band spectra, disturbances, temp. and intensity sepn. of band spectra, fluorescence and resonance, absorption and emission band spectra, spectra of polyatomic mols., radicals, active modifications and flames, and band spectra in the earth atm. and in the cosmic rays. A no. of references are given. W. R. Henn

Continuous spectra. II. Wolfgang Finkelnburg. *Physik regelmassig. Ber.* **7**, 143 52(1939); cf. *Ibid.* **4**, 35(1936).—A general discussion of the newest developments in the study of continuous spectra. Electronic spectra (ionization spectra, emission spectra, etc.), mol. spectra (theory of the spectra of mol. in general and of the spectra of the diatomic and of the polyatomic mol.), and general emission spectra are included. W. R. H.

Electronic states of diatomic carbon, and the C—C bond. Robert S. Mulliken. *Phys. Rev.* **56**, 778 81(1939). - Energies and internuclear distances are tabulated for low-energy states of C_2 and C_2^+. Bonding to other atoms shortens the C—C and C= C bond. Similar effects appear in N compds. Gregg M. Evans

The band spectrum of tin fluoride (SnF) in emission. Tosiko Yuasa. *Proc. Phys.-Math. Soc. Japan* **21**, 497–507(1939).—A discharge through a Geissler tube contg. SnF_4 at a temp. of 700° excited the emission of a system of bands, shaded toward the red, between 4599 and 6301 A. They represent a $^2\Sigma - {}^2\Pi$ transition, the levels of the low $^2\Pi$ state being sepd. by 2318 cm.$^{-1}$, and are reproduced by the formula $\nu_0 = \left.\begin{matrix}20132\\17814\end{matrix}\right\} + (418n' - n'^2) - (580n'' - 2n''^2)$ where $n' = v' + {}^1/_2$ and $n'' = v'' + {}^1/_2$. C. C. Kiess

Note on the atmospheric oxides of nitrogen. Arthur Adel. *Astrophys. J.* **90**, 627(1939). - It is suggested that the absorption bands in the earth's atm. at 7.77 μ and 8.57 μ are produced by joint absorption of N_2O and N_2O_5 since they agree in position with bands absorbed by these gases in lab. expts. C. C. Kiess

The high-frequency perpendicular fundamental vibration of the ammonia molecule. G. B. B. M. Sutherland. *Phys. Rev.* **56**, 836–7(1939).—Barker's interpretation of the band at 4 μ (*C. A.* **33**, 6156[7]) is questioned; this band is probably $\nu_3 + \nu_4$. G. M. Petty

The rotation-vibration energies of tetrahedrally symmetric pentatomic molecules. I. Wave H. Shaffer, Harald H. Nielsen and L. H. Thomas. *Phys. Rev.* **56**, 895–907(1939); cf. *C. A.* **33**, 5280[4].—A complete theory for the rotation-vibration energies of tetrahedrally pentatomic mols. has been derived to second-degree approximation for certain vibration states. The elements of the matrix *H* are given for the states $V_1\nu_1$, ν_3, $V_1\nu_1 + \nu_3$, $V_1\nu_1 + \nu_4$, $\nu_2 + \nu_3$ and $\nu_2 + \nu_4$. The selection rules governing what transitions may take place have been detd. with relations for the intensities. Bernard Lewis

Absorption spectra of a few benzene derivatives in the near infrared with large layer thicknesses. K. Rumpf and R. Mecke. *Z. physik. Chem.* **B44**, 299–312(1939). — Absorption spectra were obtained in the photographic infrared between 7000 and 10,000 A. and light paths of 1 to 3 m. The compds. studied were benzene, phenol, nitrobenzene, aniline, toluene, xylene, naphthalene, tetralin, decalin, cyclohexanone and dioxane. The 6 H atoms of the benzene ring are probably not in the plane of the ring. Coupling of the CH-valence vibration is very small in benzene so that constitutional effects of derivs. are easy to detect. Combination bands of this frequency with other vibrations are very faint. NO_2 and OH groups tighten the CH bond while NH_2 and CH_3 groups loosen it. Combination bands with the ring frequencies 1000, 1250, 1430 and 1600 cm.$^{-1}$ were found. These were also found as stable ring frequencies in the Raman effect. G. M. Murphy

Molecular associations of cholesterol and their near infrared absorption spectra. Cécile Stora and René Freymann. *Compt. rend.* **209**, 752–4(1939); cf. *C. A.* **31**, 3784[7]; **33**, 3694[4].—Examn. of the absorption spectra in the region of 0.96 μ of cholesterol at 150°, and of solns. thereof of various strengths in CCl_4, $COMe_2$, $CHCl_3$, C_6H_6, $PhNMe_2$ and a mixt. of the first 2 shows the molten cholesterol to be assocd. and that in the solns. it is assocd. with the solvent. Ovolecithin in $CHCl_3$ or CCl_4 shows no OH band, indicating the probability of either an internal anhydride or chelation; and a mixt. of ovolecithin and cholesterol shows no assocn., but the solvent used was CCl_4, and so nonaqueous. C. A. Silberrad

Physical chemical properties of the chromophoric groups, vinylene (—CH=CH—) and bivinylene (—CH=CH—CH=CH—). Complete analysis of the absorption spectrum. I. Eduard Hertel and Herta Luhrmann. *Z. physik. Chem.* **B44**, 261–85(1939).—Combination of reaction-rate expts. with other information has made it possible to analyze the absorption spectra of stilbene, diphenylbutadiene and various derivs. The total absorption can be sepd. into single regions, which can be assocd. with chromophoric groups in the mol. The effect of substituents on the absorption and the properties of the mol is discussed. G. M. Murphy

The chlorine-sensitized photochemical oxidation of chloral. W. A. Alexander and H. J. Schumacher. *Z. physik. Chem.* **B44**, 313–26(1939); cf. *C. A.* **33**, 9145[1].—The reaction was studied between 70 and 90°; it is a homogeneous chain reaction. The overall reaction is $2CCl_3CHO + O_2 = 2COCl_2 + 2HCl + 2CO$. The rate is independent of total pressure, of pressure of reaction products and, at least down to a few mm. of Hg, also of chloral and O pressure. The quantum yield at 70° is about 3×10^3 mols. per quanta. The temp. coeff. for a temp. rise of 10° is 1.14. A reaction mechanism is presented and the rate consts. and activation energies of the intermediate steps are obtained. G. M. Murphy

Comparative experiments on the decomposition of azomethane by x-rays and by light. Paul Günther and Fritz Gebert. *Z. physik. Chem.* **B44**, 203–8(1939); cf. *C. A.* **32**, 6551[9].—Mixts. of azomethane and Xe were irradiated with x-rays and with ultraviolet light, 3670 A. The dependence of photochem. decompn. on the reaction mixt. is different in the two cases. G. M. Murphy

Effect of x-rays on liquid water and ice. Paul Günther and Luise Holzapfel. *Z. physik. Chem.* **B44**, 374–82(1939); cf. *C. A.* **33**, 3682[8].—Liquid water is decompd. by x-rays with the liberation of H. The no. of H mols. is about equal to the no. of ion pairs that would be formed by an equal absorption of x-ray energy in air. At −180°, no effect could be detected with ice. The chem. behavior of water to x-rays and α-particles is similar. G. M. M.

The nature of visual observations at low light intensities. W. M. Latimer and H. A. Young. *Phys. Rev.*

56, 963–4(1939).—Magneto-optic minima are not reproducible (*C. A.* **28**, 36[8]). The causes of erroneous observations are discussed. It is possible that the optical nerve centers which respond to low-order stimuli lack the usual power of discrimination. Also, initial readings set a pattern which then becomes reproducible; an element of suggestibility or hypnotism is evidently present.
G. M. Petty

Phototropy of anils and phototropy of solns. of the leucocyanides of malachite and brilliant greens (Gaouck, Le Fèvre) **10**. Isolation and chem. constitution of bonelline [absorption and fluorescence spectra] (Lederer) **10**. Photoreactions between phenanthraquinone and aromatic aldehydes (Schönberg, Moubacher) **10**.

Intensifying and fluorescent screen for x-ray work. John Eggert and Fritz Luft (to Agfa Ansco Corp.). U. S. reissue 21,216, Sept. 26. A reissue of original patent No. 2,076,984 (*C. A.* **31**, 3792[9]).

4—ELECTROCHEMISTRY

COLIN G. FINK

New material for high-frequency furnaces. V. Maklinov. *Novosti Tekhniki* **1939**, No. 2 3, 22.—A crucible material which lasted for 150 heats in a 500-kg. high-fre- or nonferrous metallurgy was prepd. from ground quartz 56, marshallite 20, ground glass 12 and white refractory clay 12%. B. Z. Kamich

The electrolysis of fused salts: reply to an article by P. Drossbach. A. v. Zeerleder. *Z. Elektrochem.* **45**, 787(1939); cf. D., *C. A.* **33**, 6722[9]. A claim for priority over Wöhr (*C. A.* **27**, 5648) for a method of measuring the resistance of electrolytic baths. S. Glasstone

Rapid method of anodic oxidation of aluminum and its alloys. F. V. Kozlenkov. *Avtaprom yshlennost* **1939**, No. 6, 32–8.—Up to 1938 the Bengough and aloxal methods of lic oxidation of Al and its alloys were used extensively in Russia. In 1938 a rapid method (30 min.) of anodic oxidation in 10% chromic acid was introduced. The specimen is cleaned, washed in water and made the anode at 37 + 2° at a const. voltage of 40 v. and c. d. of 0.3–0.4 amp./sq. dm. Best results are obtained at a pH of 0.18 to 0.60–0.70 and a specific elec. cond. of 0.1400 to 0.0900 at 37°. B. Z. Kamich

Electroforming. Samuel Wein. *Product Eng.* **10**, 486–8(1939).—The process is discussed, the care of the plastic casts and the compn. of the electrolyte. A table shows a selected list of fusible metals. Ann N. Hird

Electrodeposition of metals from solutions with sulfamic acid or its salts. Roberto Piontelli and Alessandro Giulotto. *Chimica e industria* (Italy) **21**, 478–91(1939).—L. Cambi and R. Piontelli (*Rend. inst. lombardo sci.* **72** (1938–39)) pointed out the possibilty of utilizing solns. of HSO_3NH_2 in electrometallurgy. P. and G. detd. the current densities and other conditions necessary to obtain satisfactory deposits of various metals. The following metals give satisfactory protective or ornamental coatings: Cu, Fe, Ni, Co, Cd and Rh; the following can be refined electrolytically in sulfamic acid solns.: Cu, Ag, Fe, Ni, Co and Pb. Optimum conditions for depositing each metal are noted. Cu gives satisfactory deposits at up to 550 amp./sq. m. at temps. of 12–30°; at 37° and 300 amp./sq. m. a specular deposit is obtained. $CuCO_3$ is dissolved in the acid to give 1 *M* soln. of Cu. Ag solns. are also prepd. from Ag_2CO_3 or by reaction of Ag_2SO_4 and $Ba(SO_3NH_2)_2$. At temps. of 20–60° and currents of 40–130 amp./sq. m. deposits of Ag can be obtained. At 20° and 100 amp./sq. m. compact, finely cryst. deposits almost as good as from cyanide solns. can be obtained. Fe is deposited at 17–50° and 100–1000 amp./sq. m., the best deposits being obtained at 17° and 310 amp./sq. m. Ni is deposited at 12–40° with currents of 70–350 amp./sq. m. Excellent thin or medium coats of Ni can be obtained. Extra-heavy deposits tend to flake off. Pb in 1–2 *M* soln., with fish glue as protective colloid, can be electrolyzed from soln. with practically complete sepn. from Bi, As, Sb or Sn. Temps. of 13–22°, at 50–150 amp./sq. m., were used. The higher temp. gives more compact deposits. Th at 19° and 100 amp./sq. m. gives needle-like deposits which makes possible the prepn. of the pure metal, but adherent deposits were not obtained. Zn was electrolyzed at 14–40° and 77–1000 amp./sq. m. Deposits correspond with those obtained with sulfate solns., with no particular advantage in using sulfamate. Cd behaves like Zn. Rh solns. contg. 10–20 g./l. Rh and with excess free acid were electrolyzed at room temp. and 50–100 amp./sq. m. with Cu or Pt cathodes, and gave very good deposits of Rh. All known salts of sulfamic acid except the basic Hg salt are sol. in water. Attempts at depositing Sn, Mn, Bi, Cr, Sb and As were unsuccessful, in fact salts of Bi, Sb and As are not known, while the Sn salt is very slightly sol. Manganous salts oxidize very readily. The possible deposition or refining of Pt or Au by means of sulfamic salts is still under investigation, as well as possible applications to quant. analysis.
A. W. Contieri

The electrodeposition of silver from thiosulfate solutions. Robert Weiner. *Z. Elektrochem.* **45**, 757–9(1939); cf. *C. A.* **34**, 3277[7].—Bright electrodeposits of Ag can be obtained from a bath contg. 40 g. Ag (as AgCl), 170 g. $Na_2S_2O_3.5H_2O$, 20 g. $NaHSO_3$ and 50 g. Na_2SO_4 per l., at c. ds. of 0.3–0.5 amp./sq. dm. The $NaHSO_3$ prevents oxidative decompn. of the Ag-S_2O_3 complexes, and the Na_2SO_4, which may be replaced by Cl^-, acetate or citrate, facilitates soln. of the anode. NH_4Cl, Na_2CO_3, NaOH, NaCNS and NH_3 are harmful, but CN and PO_4^{---} have a small beneficial effect. Capillary-active substances, e. g., Turkey-red oil, and colloids have little or no effect on the deposits. S. Glasstone

The electrolytic preparation of silver oxide. Kálmán Mérei. *Magyar Chem. Folyóirat* **45**, 123–30(1939).—Various expts. were made. The optimum conditions for the electrolytic prepn. of Ag_2O are those of Lorenz (*Z. anorg. Chem.* **12**, 436(1896)): concd. electrolyte (25–30% $NaNO_3$) at a low c. d. (0.5 amp./sq. dm.) at room temp. and anodes of pure Ag and cathodes of Ni or Fe closely spaced. The potential of the cells ranged from 1.7 to 2.8 v. For 1 g. Ag_2O 0.417–0.664 watt-hrs. were required; current efficiency 91.1 to 98.4%. In 18–60 min. 1.491–2.282 g. Ag_2O was produced. S. S. de Finály

A graphic method for the calculation of the current density at a given point during electroplating. I. Ya. Bogorad. *Korroziya* **4**, No. 2, 155–8(1938); *Khim. Referat. Zhur.* **2**, No. 1, 78(1939).—The detn. of the cathode c. d. at a given point is important to obtain deposits of a definite quality, especially for Cr-plating relief surfaces. The graphical method permits detn. of the c. d. from the velocity of the deposition of the metal on the cathode, which is measured at the same point. The velocity of the deposition on the surface of the cathode is detd. by $\delta = (KPD)/d \times 1000$ where δ is the thickness of the deposit in mm. deposited in 1 hr., K the electrochem. equiv., P the current efficiency, D the cathode c. d. in amp. per sq. dm., and d the density of the deposited metal. With a current efficiency of less than 100% the yield changes with the change of the c. d. The formula thus contains 2 unknown quantities. The dependence of the yield on D is found graphically. On the basis of exptl. data a curve is constructed of the yield depending on the current for $D = 1$. Another curve $\delta = f(D, P)$ is constructed from points detd. from the formula and from curve 1; from this the c. d. is detd. depending on the velocity of deposition at a given point. By detg. the deposition velocity from curve 2 the cathodic c. d. is found, and then from curve 1 the current efficiency is detd. Thus, the detn. of the deposition velocity is

simplified to the detn. of the thickness at a given point by one of the usual methods. W. R. Henn

The antimony electrode. Yrjö Kauko and Laina Knappsberg. *Z. Elektrochem.* **45**, 760-9(1939).—See *C. A.* **33**, 6726[1]. S. Glasstone

Cathodic polarization during deposition of metals from nonaqueous solutions. A. I. Levin and O. A. Esin. *Trudy Ural. Ind. Inst.* **1938**, No. 6, 43-51; *Khim. Referat Zhur.* **2**, No. 2, 10(1939).—Curves for the cathode potential *vs.* c. d. were prepd. based on the exptl. data for the discharge of Cu^{++} and Cu^{+} ions and for Ag^{+} and Zn^{++} ions. The expts. are described. Formamide and pyridine were used as solvents. The polarization in the Cu^{++} discharge was studied with a $CuSO_4$ soln. in formamide; and in the Cu^{+} discharge, with a CuCl soln. In both cases free HCOOH was present. Polarization during the discharge of Ag^{+} was studied in a 0.1 *N* $AgNO_3$ soln. in pyridine. Pyridine was also solvent for the ZnI_2 solns. The curves show that during the discharge of Cu ions a considerable chem. polarization takes place (besides the usual concn. polarization) which is expressed by the Erdey-Gruz and Volmer equation which presupposes that the retardation of the formation of the crystal grains is the cause for the polarization. During the deposition of Ag a chem. polarization is also observed, but its abs. value is considerably smaller than that for Cu. For Zn^{++} as well as for Cu^{+} only the concn. polarization is observed. Curves are shown for the change in cathode polarization with time, for the discharge of Zn^{++} on a Zn cathode from solns. of ZnI_2 in pyridine and of $ZnCl_2$ in acetone. These curves indicate a special initial polarization which had been found by L. and E. previously in the study of cathodic polarization during the deposition of Cu from aq. solns. W. R. Henn

Electrolysis of mixtures of pivalic acid salts with nitrates. Fr. Fichter and Raymond Gunst. *Helv. Chim. Acta* **22**, 1300-7(1939).—The electrolyte (150 cc.) contained 40.8 g. pivalic acid, 16 g. NaOH and 17 g. $NaNO_3$ and was placed in the anode compartment with Pt anode. The cathode compartment contained 2 *N* Na_2CO_3. Electrolysis was carried on for 5 hrs. at 4 amp. (0.174 amp./sq. cm. of anode). The following products of the electrolysis were definitely identified: Me_3CONO, Me_3CCOOH, Me_3COH, $Me_2C{:}CH_2$, $Me_2C(ONO_2)CH_2ONO_2$, $Me_2COH\text{-}CH_2OH$, $Me_3CCOOCMe_3$, $Me_2C(ONO_2)OCMe_3$ and $Me_2COHCH_2OCMe_3$ Oden E. Sheppard

The formation of formaldehyde by acetate electrolysis. Emil Baur. *Helv. Chim. Acta* **22**, 1120-3(1939).—Electrolysis of 50% AcOEt, 25% AcOH and 25% AcOK at 0.2 amp. for 80 min. without a diaphragm and with stirring gave concns. of 14.7 mg. HCHO per l. and with a diaphragm only 8.8 mg. Omission of AcOEt resulted only in traces of HCHO being formed. The primary anodic product is probably AcO_2Ac which on hydrolysis forms AcO_2H and cathodic reduction of this yields CH_4 and HCO_2H which decomps. to HCHO and O_2. O. E. S.

Chemical action of the electrical discharge. XVIII. Production of nitric oxide in the high-frequency arc. Refinements and new results. E. Briner, J. Desbaillets, F. Richard and H. Paillard. *Helv. Chim. Acta* **22**, 1096-1107(1939); cf. *C. A.* **31**, 3247, 6136; **33**, 1221[6].—Methods of analysis used in previous work in this field reported by the authors have been found unreliable for NO at low pressures and so previous values are in error. By use of the Devarda alloy method for detg. NO, new values were obtained with pressures of 28 to 710 mm., arc frequencies about 10^7 per sec., various concns. of N and O, various current densities and various oscillator connections. Good yields are obtained by circulating equal molar mixts. of N and O at reduced pressures through the arc at as low c. d. as will maintain a stable arc. Oscillator connection was studied as it exerts a marked effect on yield. Best yields were of the order of 200 g. HNO_3 per kw.-hr. Oden E. Sheppard

Modern vacuum practice in electronics. Richard S. Morse. *Electronics* **12**, No. 11, 33-6(1939).—The success of the electron tube is dependent upon the production of high vacuum. The lowest pressure attainable with a vapor pump corresponds to the vapor pressure of the working liquid. Tests are recorded to demonstrate the advantages and the stability of Octoil and Octoil-S (low vapor pressure fluids) with a 4-compartment, 3-jet all-glass fractionating pump. C. G. F.

Miniature battery tubes. Kenneth G. Bucklin. *Electronics* **12**, No. 11, 27-8(1939).—For the 45 v. "B" battery portable radios new tubes have been developed about $^3/_4$" in diam. and $2^1/_8$" long. With the exception of the output tube, which contains 2 filaments in parallel, the new tubes have a filament rating of 50 milliamp. at 1.4 v. C. G. F.

Ceramic spacer material for electron-discharge devices (U. S. pat. 2,175,707) **19**. Dewaxing oils [by electrodeposition] (U. S. pat. 2,174,938) **22**. Porous rubber for battery separators (U. S. pat. 2,175,798) **30**.

Primary electric battery. Albert 1. Eddy (to Thomas A. Edison, Inc.). U. S. 2,175,885, Oct. 10. Various details of a battery which may have electrodes of Zn and Cu oxide and an electrolyte such as KOH soln.

Dry cell. Albert I. Eddy (to Thomas A. Edison, Inc.). U. S. 2,175,686, Oct. 10. Various structural details.

Storage battery. Lester E. Lighton (to Elec. Storage Battery Co.). U. S. 2,175,993, Oct. 10. Structural details.

Electric condenser. Preston Robinson and Wm. M. Allison (to Sprague Specialties Co.). U. S. 2,174,840, Oct. 3. A combined electrode and dielec. layer for an adjustable condenser comprises a conductive layer of film-forming metal such as Al and a dielec. layer immediately adhering and baked to the conductive layer and consisting of an oxide of the metal and having a hard outer surface and a portion less hard and more elastic adjacent to the conductive layer.

Electrolytic condensers. Preston Robinson (to Sprague Specialties Co.). U. S. 2,174,841, Oct. 3. A process for the manuf. of electrolytic condensers involves subjecting an etched foil of a film-forming metal such as Al to a surface treatment with a soln. having a small amt. of undissocd. acid such as oxalic acid the anions of which are substantially entirely univalent ions and which comprises as main constituent an acid, forming in the soln. a porous film having a thickness of about 5-15 microns on the metal, and, without intermediate hydrolyzation of the so-treated surface, subjecting the foil to a surface treatment in a second soln. such as a dil. NH_4 soln. to change, in the first soln. remaining on the foil, the univalent ions to bivalent ions, and thereafter subjecting the foil to a dielec. film formation.

Electrolytic cleaning of iron or steel wire in dilute sulfuric acid. Ferdinand A. Herrmann. U. S. 2,174,722, Oct. 3. Various details of operation.

Electric arc device for burning in furnace linings such as those of metal or glass-melting furnaces. Wm. E. Moore and William B. Wallis (to Pittsburgh Research Corp.). U. S. 2,174,927, Oct. 3. Various structural and operative details.

Electroprocessing apparatus with tanks and work carriers. Guerin Todd (to Hanson-Van Winkle-Munning Co.). U. S. 2,175,788, Oct. 10. Various structural, mech. and operative details.

Apparatus for effecting the electrostatic separation of materials such as dust and smoke from air or flue gases. Harold W. Bartlett (to Rosenberg Bros. & Co.). U. S. 2,174,681, Oct. 3. Various structural, elec. and operative details.

Selenium rectifier with carrier electrodes of light metal such as aluminum. Fritz Brunke and Werner Koch (to General Elec. Co.). U. S. 2,175,873, Oct. 10. A method of producing dry-plate elements of the Se type involves providing a carrier electrode composed of a light metal such as Al, Mg or Be having on it an oxide film, applying a plurality of particles of finely divided C to the surface of the film, applying a layer comprising Se to the C-treated surface, and applying a counter electrode such as Wood's metal to the layer (the amt. of C being so limited that the

light metal acts chemically with the Se layer). Cf. *C. A.* **33**, 7677[8].

Dry-plate electric rectifiers. Fritz Brunke (to General Elec. Co.). U. S. 2,175,016, Oct. 3. A method of producing an element for a dry-plate device having a carrier electrode comprising Al, Mg or Be or one of their alloys involves exposing the electrode to a mixt. of Se vapor and I vapor in the presence of a chemically neutral gas such as N (suitably under superatm. pressures).

Electric fuse comprising lead salts of nitrophenols. Lawton A. Burrows and Walter E. Lawson (to E. I. du Pont de Nemours & Co.). U. S. 2,175,250, Oct. 10. An elec. fuse comprises a metal fuse bar assocd. in heat-transfer relation with a Pb salt of a nitrophenol contg. not more than 2 nitro groups, such as Pb dinitro-*o*-cresylate.

Generating electricity in a gas cell. Herbert H. Gregger. U. S. 2,175,523, Oct. 10. A process of generating electricity comprises introducing a fuel gas into a gas cell at one electrode thereof where it comes into contact with an electrolyte comprising a fused mixt. of alkali and alk. earth metal carbonates and halides and reacts chemically therewith, releasing electrical charges to the electrode and simultaneously introducing at least one gas contg. O and a CO_2-contg. gas at the other electrode where it comes into contact with the electrolyte and reacts chemically therewith, releasing electrical charges which are imparted to the other electrode.

Protective cut-offs or warning signals for electrical devices. Charles F. Hill (to Westinghouse Elec. & Mfg. Co.). U. S. 2,175,893, Oct. 10. A dielectric such as $FeCl_3$ is used which when decompd. by an elec. arc evolves a gas such as HCl which reacts with a metallic hydroxide such as $Fe(OH)_3$ together with a member such as cellulose acetate having a high ohmic resistance to the flow of elec. current applied to such member and a metallic hydroxide such as $Fe(OH)_3$ which reacts chemically with the evolved gas to produce a material of good elec. conducting character.

Photoelectric cathodes. Leslie E. Flory (to Radio Corp. of America). U. S. 2,175,888, Oct. 10. A light-transmitting support such as glass or mica carries on one side a light-transmitting film of metal such as Pt, Al, Ni or Cr with an overlying layer of minute photosensitive globules of material such as Ag. Cf. *C. A.* **33**, 2049[7].

Cathode for electric discharge devices. Georg Galdies, Hermann Krefft and Hermann Kummer (to General Elec. Co.). U. S. 2,175,345, Oct. 10. A method of producing a thermionic cathode involves sintering a mixt. of an alk. earth metal compd. such as BaO or SrO and W powder, forming a paste of the sintered material with alc., and placing the paste within a helix of W wire to fill completely the space within the helix, and again sintering the material in a nonoxidizing atm.

Mosaic electrodes for television tubes. Albert Rose (to Radio Corp. of America). U. S. 2,175,701, Oct. 10. Electrodes are prepd. by coating the exposed surface of a wire-mesh screen which may be formed of Ni with an elec. insulating substance such as an enamel and filling the interstices of the screen with a mixt. of paraffin and powd. material such as Ag or Ag oxide which when fired sinters and becomes electrically conducting while maintaining the screen at a temp. approx. the m. p. of the paraffin to form individual sepd. plugs in the interstices of the screen, cooling the screen to solidify the paraffin, applying a quantity of the powd. material to each side of the prepd. screen, mechanically working the powd. material into the plugs to remove the excess of the binder from the exposed surface of the insulated screen, and firing to volatilize the binder and sinter the powd. material.

Television transmitting tube. Harley A. Iams (to Radio Corp. of America). U. S. 2,175,691, Oct. 10. A target electrode positioned to be scanned by an electron beam comprises a Cu foundation plate carrying an integral layer of Cu_2O and an overlying discontinuous mosaic of translucent particles of sputtered metal such as Cs. U. S. 2,175,692 also relates to details of television transmitting tubes.

Electron emitters. Ernest A. Lederer (to Radio Corp. of America). U. S. 2,175,696, Oct. 10. A core of metal such as Ni is coated with MgO and Ba azide and is heated in a nonoxidizing environment to solidify the MgO and cause it to adhere to the core and to decompose the azide to metallic Ba and disperse the latter through the oxide.

Electron-discharge devices suitable for transmitter tubes. Peter Knepen (to General Elec. Co.). U. S. 2,175,695, Oct. 10. An electrode is used formed of Ni, Ta or Mo carrying a layer of C and an overlying layer of a metal such as Zr having a high m. p. and good heat-radiating and gettering properties.

Electric discharge devices rendered luminescent by discharge through them. John T. Randall (to General Elec. Co.). U. S. 2,174,449, Sept. 26. A source of light comprises in combination a high-pressure Hg vapor elec. discharge lamp having a quartz envelope, and luminescens material assocd. therewith and exposed to the radiation from the lamp, the luminescent material contg. three different components, one component comprising a fluorescent Zn Cd sulfide contg. 20–40% of CdS activated by copper, another of the components comprising a fluorescent Cd silicate or Zn Be silicate activated by Mn, and a third component which emits blue luminescent light upon excitation by radiations from the lamp in the range of 4000–2200 A.

Composite bodies such as vacuum tubes. Hans Pulfrich (to General Elec. Co.). U. S. 2,174,390, Sept. 26. As a material for bonding with W, Mo or the like, use is made of a low-dielec. loss ceramic material such as is formed by firing at an elevated temp. a mixt. which may be formed of Be oxide 10–40, hydrous Mg silicate 15–36 and hydrous Al silicate 36–67.5 parts, such ceramic material having a coeff. of linear expansion not substantially exceeding 50.10^{-7} per degree.

Ignitron apparatus such as that containing neon or argon and mercury. Joseph Slepian (to Westinghouse Elec. & Mfg. Co.). U. S. 2,175,924–5, Oct. 10. Various structural, elec. and operative details of app. suitable for low potential operation.

Iron phosphate from ferro-phosphorus. Lewis H. D. Fraser. U. S. 2,173,103, Sept. 19. Ferro-P is used as anode in an electrolyte consisting essentially of an aq. soln. of an alkali metal salt of a strong inorg. acid (such as one of Na sulfate and H_2SO_4), and a chemically inert conductor, such as Pb or C, is used as a cathode, employing a d. c. at an anode c. d. of not more than 100 amps. per sq. ft. between the anode and cathode, to produce insol. Fe phosphate.

5—PHOTOGRAPHY

E. R. BULLOCK

A new color cinematographic process (Agfacolor Negativ-Positiv process). J. Eggert. *Phot. Ind.* **37**, 702 (1939).—Complementarily dyed negatives are produced by color development, and from these prints are made. Diffusion-fast constituents for the color development have been incorporated in the manuf. of the taking and reproducing films. E. R. B.

Influence of pressure and development on the solarized latent photographic image. Anna Joyce Reardon. *J. Optical Soc. Am.* **29**, 427–31 (1939); cf. *C. A.* **32**, 8966[2].—Using Eastman P. M. C. Bromide No. 1 paper and Eastman Portrait (nitrate) Films, R. detd. the effect of pressures up to 387 kg. per sq. cm. and of up to 1356 kg. per sq. cm., resp., applied during exposure, on the ds. after development by 2 or all of 4 methods. These are: chem. development with restrained hydroquinone, and phys. development (1 prefixation and 2 postfixation methods) according to Odell (*C. A.* **27**, 4182). The result obtained,

in all cases, was a decrease in the d., this effect increasing with increasing pressure, without removal of the solarization when solarization was shown in the control expts.
E. R. Bullock

Role of the oxidation products in development. H. Staude. *Phot. Ind.* **37**, 701 2(1939); cf. *C. A.* **32**, 6564⁴. —From the results of expts. with different developer solns., each of which had been carefully freed from the oxidation product of the particular developing agent, it appeared probable that such an oxidation product is essential for the initiation of development. S. considers that the oxidation product favors adsorption of the developing agent onto the exposure nuclei and so causes the reducing agent to be a photographic developer.
E. R. B.

Standardization of photographic sensitometry based on the addition law. A. van Kreveld. *J. Optical Soc. Am* **29**, 327–36(1939).—From the abs. spectral sensitivities, measured in connection with a recent investigation on darkroom illumination, of 26 well-known films and plates, various practical sensitometric magnitudes have been computed by means of the addn. law (*Brit. J. Phot.* **82**, 388(1935)). Conclusions: (1) The total sensitivity of panchromatic emulsions does not greatly exceed that of orthochromatic and noncolor-sensitive emulsions. (2) For all (even the panchromatic) emulsions, the sensitivity to W incandescent light is lower than to daylight. (3) Color sensitivity of all the emulsions is far less than is desirable. (4) Color sensitivity (contrary to common opinion) does not vary significantly with the kind of illumination. (5) Five sensitometric nos. which satisfy all practical requirements are: the total sensitivity to daylight, the total sensitivity to W light and the color sensitivities, compared with blue, to green, yellow and red, resp.
E. R. Bullock

Mordanting bath for dye-toning transparencies. P. Hanneke. *Phot. Chronik* **45**, 368(1938). A mordanting bath suggested is: H_2O 1 l., $CuSO_4.5H_2O$ 40 g., KCNS 20 g., K citrate 60 g. and AcOH 30 cc. After the transparencies are mordanted and washed, it is recommended to dye them in a soln. of rhodamine B, thoflavine T or methylene blue 2 g. or less, with AcOH 2 cc. or less, per l.
L. E. Muehler

Sulfonated long-chain secondary alcohols as wetting agents. R. Bredeau. *Rev. prod. chim.* **41**, 289–91; *Science ind. phot.* **9**, 271(1938). The Tergitols, which are the Na sulfonates of secondary aliphatic alcohols contg. 8–20 C atoms, are recommended as wetting agents for photographic use. The even flow of developer over sensitive materials is ensured by the addn. of 0.5–1.0% of Tergitol 7; an alk. soln. contg. Tergitol 4 is used for washing bottles, and Tergitol 08 can be added to acid fluxes used for soldering.

Photographic fixing compositions. Robert B. Barnes (to American Cyanamid Co.). U. S. 2,174,494, Sept. 26. An amidine salt such as guanidine thiosulfate is used in thiosulfate fixing compns. for use with Ag halides, to increase the fixing speed.

Sensitized coating for photographic and printing purposes. Anton F. Greiner. U. S. 2,174,629, Oct. 3. A polymerized vinyl alc. is used with a catalyst such as $(NH_4)_2Cr_2O_7$ reactive with the polymerized vinyl alc. in the presence of actinic rays to render it less sol.

Modification system for correcting a set of yellow, red and blue separation photographic negatives. Wm. J. Wilkinson (50% to Michle Printing Press and Mfg. Co.). U. S. 2,174,812, Oct. 3. Numerous details of procedure are described.

Color-sensitive photographic plates. Joseph S. Friedman and Arthur Bruck (to Color Processes, Inc.). U. S. 2,175,836, Oct. 10. A method of producing multicolor-sensitive stratification of the light-sensitive emulsion on a photographic plate having a transparent carrier which is to be placed toward the source of light on exposure, and to produce the image in one color value adjacent the carrier and in another color value away from the carrier, involves providing a plate composed of the transparent carrier coated with a blue-sensitive gelatin emulsion of an insol. Ag halide, immersing the plate in a substantially nonaq. org. solvent soln. such as an iso-PrOH soln. of a color-sensitizing dye which will sensitize the emulsion to one of the primary colors other than blue, such as pinacyanol, without swelling or penetrating the emulsion (penetration being prevented by a sufficient concn. of the org. solvent used), removing the plate and drying to form a substantially nonpenetrating surface coating of the sensitizing dye upon the emulsion without substantial sensitization of the emulsion, and then treating the dried plate with an aq. soln. of an org. solvent such as an aq. iso-PrOH soln. contg. auramine to cause a slight swelling and to cause a limited diffusion of the deposited surface coating of the sensitizing dye into the outer portion of the emulsion without penetrating the portions of the emulsion adjacent the carrier, whereby upon exposure of the plate with the carrier facing the source of light the portion of the emulsion adjacent the carrier will reproduce the image in blue values while the portion of the emulsion away from the carrier will reproduce the image in values corresponding to the sensitization obtained by the sensitizing dye.

6—INORGANIC CHEMISTRY

W. C. FERNELIUS AND L. L. QUILL

Action of chlorine on calcium oxide. Marcel Lemarchands and Ernesto Matiz Umana. *Compt. rend.* **209**, 757–9(1939).—Anhydrous Cl scarcely acts on anhydrous CaO. The results obtained when Cl reacts on CaO which is hydrated to a varying degree (**X** = 5.8–85%) indicate: (*a*) The percentage of H_2O replaced by Cl is independent of the amt. of hydration if **X** is less than 45%; (*b*) the case of chlorination is increased if **X** is greater than 50%, but the amt. of H_2O of hydration replaced by Cl decreased with increasing **X**. The explanation given was that when **X** is small a larger proportion of CaO is present to reabsorb the H_2O expelled by the Cl, thus rendering the H_2O available again for exchange with the Cl.
C. A. Silberrad

Solubility of the double fluorides of aluminum and of the basic metals. J. Tananaev and Sh. Talipov. *J. Gen. Chem.* (U. S. S. R.) **9**, 1155–7(1939). —An exptl. method is given for the prepn. of Na_3AlF_6, K_3AlF_6 and $(NH_4)_3AlF_6$ whose compns. correspond exactly to their formulas. The expts. were performed in a thermostat at 25° in vessels having Hg seals. Twelve hrs. was required for the satn. After the equil. had been reached a definite vol. was dried and weighed. The analysis of the dry residue corresponded to the formula M_3AlF_6. Expts. were also performed for the detn. of the soly. of Na_3AlF_6 and of K_3AlF_6 at different temps. At 0, 25, 50, 75 and 100° the soly. of Na_3AlF_6 in g./1000 g. of the soln. was 0.3480, 0.4175, 0.7932, 0.9302 and 1.3500 and that of K_3AlF_6 in 1000 g. of the soln. 0.8604, 1.4288, 2.6125, 3.4511 and 4.5828, resp. The soly. of $(NH_4)_3AlF_6$ at 0, 25, 50, 55, 60, 65, 75 and 100° was 4.3128, 7.6585, 12.3622, 12.1217, 11.7034, 11.2510, 11.0132, 7.4190, resp. In contrast to the soly. of Na_3AlF_6 and K_3AlF_6 the soly. of $(NH_4)_3AlF_6$ does not rise steadily, but it has a max. at about 50°, after which it decreases sharply. At 10° and 25° the values for the soly. are the same. The unusual behavior of $(NH_4)_3AlF_6$ is evidently due to a change in its cryst. structure. A supposition that the salt dissolves incongruently was not verified, since the compn. of the dry residue was close to $(NH_4)_3AlF_6$. The difference in the solubilities of the 3 investigated salts led to an attempt to use a soln. of $(NH_4)_3AlF_6$ for the pptn. of the ions of Na and K. Preliminary expts. showed that both ions (used singly or together) were quantitatively pptd. as Na_3AlF_6 and K_3AlF_6. Since the soly. of each ppt. was very small,

attempts were made to det. the amt. of Na and K by microchem. means. Three graphs, 3 tables and 3 references are given. W. R. Henn

The nature of the precipitates obtained by adding sodium silicate to magnesium sulfate. R. Roseman, M. B. Levin and H. Eisenberg. *Am. J. Pharm.* **111**, 400–6 (1939).—The prepn. of a group of Mg silicates by the interaction of Na silicate and Mg sulfate (mols. $Na_2O.3.27SiO_2$/mols. $MgSO_4.7H_2O$ = 0.51–2.03) is described. Careful analyses of the products (mol. ratios, $MgO:SiO_2$ = 1:3.08–1:4.31) have furnished the data needed for plotting curves, useful in detg. the proportions of reactants required to produce any silicate in the range studied. A synthetic Mg silicate, in which the mol. ratio $MgO:SiO_2$ is the same as the mol. ratio $Na_2O.SiO_2$ in the Na silicate used in its prepn. (1:3.27), results from the interaction of equal numbers of mols. of the Na silicate and the Mg sulfate. The pptd. Mg silicates can be washed free of Na (and sulfate), even where a considerable excess of Na silicate has been employed as precipitant. W. G. Gaessler

Investigations in the domain of the chemistry of "inert" gases II. The hydrates of argon and neon. B. A. Nikitin. *J. Gen. Chem.* (U. S. S. R.) **9**, 1167–75(1939); cf. Khlopin and Gerling, *C. A.* **31**, 3339[3].—The coppttn. with isomorphic substances is the new method for the prepn. and investigation of the dissocg. compds. During the formation of the hydrate of SO_2 from the gas and ice an isomorphic absorption of A takes place which is distributed between the gaseous phase and the crystals according to Berthelot-Nernst law. In the expts. with A and Ne about 1 ml. of these gases and a large excess of SO_2 were taken. The app. for the prepn. of the hydrates of A and Ne consisted of a U-shaped tube (approx. 50 ml) of which one end was drawn into a capillary, and both ends were provided with stopcocks. About 30 g. of finely divided ice was added to the tube, and the vol. of the unfilled space detd. Into the evacuated tube a definite amt. of SO_2 was introduced. The hydrate was formed after 1–2 mm. when a definite amt. of the inert gas was added. The reaction tube was left at this temp. for several days. The fine crystals of the hydrate of SO_2 rapidly recrystd. (through the gaseous phase). After a definite time the reaction tube was washed with a mixt. of CO_2 and SO_2 in which the partial pressure of SO_2 was equal to the dissocn. pressure of the hydrate of SO_2. This prevented dissocn. of the hydrate during washing. The washed gases entered first the capillary of the reaction tube where they were cooled. Specially conducted control expts. showed that in the absence of SO_2 all A is washed away and it is not absorbed by ice. The inert gases were analyzed in the app. of Khlopin and Gerling (cf. *C. A.* **31**, 3339[3]). The mean distribution const. D at −10.5° was 0.0078. Ne was also absorbed by the crystals of the SO_2 hydrates, but only 1.5–3.5% of Ne can be transferred to the residue. For Ne the distribution const. at −8.5° was of the order of 4×10^{-5}. No Ne was observed in the residue under the same conditions. This points to the existence of a formerly unknown hydrate $Ne.6H_2O$. The inert gases have many analogs in the formation of mol. chem. compds. This analogy is expressed not only in the same compn. and structure of the crystallohydrates of the inert gases as have the other mol. crystallohydrates, but they form mixed crystals with the other hydrates. Five tables and 12 references are given. **III. Separation of the "inert" gases from each other by chemical means.** *Ibid.* 1176–81 (1939).—By isomorphic coppttn. with the hydrate of SO_2 it was possible to convert Rn quantitatively to a hydrate while He, Ne and A remained in the gaseous phase. It was also possible under other conditions of the expt. to ppt. A practically quantitatively and to sep. it from He and Ne which remained in the gaseous phase. Such a method for the sepn. of the "inert" gases should be called a chem. method since it is based on the different stabilities of the hydrates of the "inert" gases. According to its chem. properties A is closer to Rn than to Ne. It is easier to sep. A from Ne by the hydrate method than from Rn. Seven tables and 3 references are given. W. R. Henn

Complexes formed by molybdic acid in aqueous solution. Mme. Hugues Frey (Zina Soubarew). *Compt. rend.* **209**, 759–60(1939); cf. *C. A.* **33**, 37[2], 5765[8].—Crystd. addn. compds. of the type $2MoO_3.X.n\,H_2O$ [X = glycine, hexamethylenetetramine, antipyrine, imidazole, or *d*-arabotetrahydroxybutyl-4 (or 5)-imidazole (I)] were prepd. (N = 1–3, usually being 2). I was found to be similar to ammoniomannitodimolybdic acid (cf. *C. A.* **33**, 5765[8]), forming a well-crystd. and very sol. NH_4 salt $[Mo_2O_7H.C_7H_{12}N_2O_4]NH_4$. The other complexes are less stable. The conductimetric method shows that the imidazole compd. has an active H, which is replaced by Na.

C. A. Silberrad

7—ANALYTICAL CHEMISTRY

W. T. HALL

Qualitative and quantitative chemical analysis by line emission spectra. Ralph A. Sawyer. *Applied Phys.* 10, 741–50(1939).—A review with 38 references. E. H.

Fractional centrifugation as a means of separation in the analysis of a mixture. A. Gourevitch. *Ann. chim. anal. chim. appl.* **21**, 291–7(1939).—Without using any chem. reaction, it ought to be possible to sep. compds. in a mixt. by means of evapg. the aq. soln. to dryness in such a way that very small crystals are obtained, adding a liquid in which the crystals are insol., triturating to form a paste, adding another liquid in which the first liquid is sol. but which does not dissolve any salt and subjecting the mixt. to centrifugation. The procedure was tested with $K_2Cr_2O_7$, d. 1.99 and KCl d. 2.69. The aq. soln. was evapd. to dryness, triturated with 9 times its wt. of thymol and some glass, and after 3–4 days some of the mixt. was mixed with a relatively large quantity of $CHBr_3$ + C_9H_{20} which was mixed so that its d. was a little greater than that of KCl and less than that of the $K_2Cr_2O_7$. Gentle centrifugation brought the KCl to the surface, where it could be skimmed off, and the $K_2Cr_2O_7$ formed a mass at the bottom of the tube. W. T. H.

Necessity of reducing analytical weights to normal temperature and pressure. C. J. van Nieuwenburg. *Atti X° congr. intern. chim.* **3**, 451–4(1939) (in French).—If it is desired to know the exact weight, which is rarely the case, of 10 g. to within 0.001 mg., it is necessary to take into account the fact that the buoyancy of the wts. and sample in air varies appreciably with changes in temp. and atm. pressure. A simple app. is shown which makes it easy to apply the correction so that the weight corresponds to the wt. at 0° and 760 mm. of Hg pressure. W. T. H.

The preparation of an analytical standard for chromite. A. V. Shein and M. V. Mil'kovskaya. *Trudy Ural. Nauch.-Issledovatel. Inst. Geol. Razved. i Issled. Mineral. Syr'ya* **1938**, No. 3, 335–54; *Khim. Referat. Zhur.* **2**, No. 1, 67(1939). The methods used for analyzing chromite are described. W. R. Henn

Adsorption indicators for the determination of halides. A. M. Hal'perin. *Farmatsiya* **1938**, No. 3, 7–12; *Khim. Referat. Zhur.* **2**, No. 2, 82(1939).—For the detn. of the chlorides, bromides and iodides in dil. solns. by titration in the presence of adsorption indicators, the superiority of the method of Fajans over the method of Mohr is shown. Besides fluorescein good results in the titration of the chlorides were obtained with azolitmin, metanil yellow and diphenylamine blue. The protective colloids (dextrin and gelatin) prevented coagulation at the equiv. point, but did not affect the accuracy of the titration. Bromothymol blue, aniline red and Congo red were satisfactory for the detn. of bromide. Eosin and fluorescein were also suitable for dil. solns. All indicators used for the detn. of the bromides could also be used for titration of 0.05–0.1 N iodide solns. For 0.01 N solns. only Congo red

could be used, and for 0.0005 *N* solns. none of the indicators mentioned was suitable. Three comparative tables from which the magnitude of deviations from the gravimetric results can be seen, and a table for the changes of color are given. W. R. Henn

Quinaldinic acid as a reagent for the separation and determination of copper and cadmium. Anil Kumar Majumdar. *Analyst* **64**, 874 6(1939).- Shennan, *C. A.* **33**, 1621[2], has claimed that the quinaldinic acid method of Ray and Bose, *C. A.* **28**, 1625[2], is excellent for detg. Cu and Cd when only one of these elements is present but he found the sepn. of Cu from Cd unsatisfactory. It is now shown that this conclusion is wrong. The sepn. of Cu from Cd by means of quinaldinic acid is excellent at pH 1.22-2.01. W. T. H.

Colorimetric determination of aluminum. A. A. Rode. *Problemy Sovet. Pochvovedeniya* **1938**, No. 6, 53 60; *Khim. Referat. Zhur.* **2**, No. 2, 73(1939). -R. modified the oxine method of the colorimetric detn. of Al for the investigation of *soil solns.* and of their Al content. The difficulties arising from the presence of Fe were overcome by changing Fe^{+++} to $Fe(CNS)_3$ and removing it by shaking with a mixt. of ether with Am alc. Take 3–7 cc. of the soln. contg. 50–400 γ of Al_2O_3, acidify with 2–3 drops of coned. HCl, add 1 cc. of a 10% soln. of NH_4CNS and 6 cc. of a mixt. of ether with Am alc. (2:5). Shake well for 1 min., allow to stand for 2–3 min. and remove the colored liquid with a pipet. Repeat the extn. with the mixt. of ether with Am alc. until a colorless liquid is obtained (usually 3–4 extns. are sufficient). Decomp. the excess NH_4CNS and org. substances by heating with 2 cc. of coned. HNO_3. Proceed as in the pptn. of Al by the oxine method. Dissolve the Al hydroxy quinolate in a mixt. of ether with HCl and color the soln. by treating it with 1 cc. of a soln. of sulfanilic acid, 1 cc. of a $NaNO_2$ soln. and 10 cc. of a 4 *N* NaOH soln. Compare the colored soln. immediately with the standard. W. R. Henn

Rapid determination of chromium and manganese in steel. K. Dietrich. *Metallwirtschaft* **18**, 811–13(1939).— Treat 0.5 g. of metal with 5 ml. of coned. HNO_3 + 5 ml. coned. HCl. To the resulting soln. add 15 ml. of $HClO_4$ and evap. till fumes of this acid are evolved. After 3 min. of fuming, cool, add a little water and transfer to a 200-ml. measuring flask. Add an aq. soln. of 1 g. NaF, dil. to the mark, mix and measure the chromic acid color in a "Leifo" polarization photometer. Beer's law holds for samples contg. not more than 1% Cr but for larger quantities an aliquot part of the soln. must be taken for the colorimetric measurement. For the Mn detn. take 0.1 g. of sample, treat with a mixt. of 4 pts. coned. HNO_3, 1 pt. coned. H_2SO_4 and 5 pts. water, add 10 ml. of 28% H_3PO_4, 10 ml. of 0.5% $AgNO_3$ soln. and 10 ml. of 20% $(NH_4)_2S_2O_8$ soln. and allow the mixt. to stand a short time until all foaming ceases from decompn. of the persulfate excess. Dil. to exactly 100 ml. and det. the extinction coeff. of the soln. Excellent results were obtained for both Cr and Mn in the analysis of 12 samples for Cr and 11 samples for Mn. W. T. H.

Determination of copper in cast iron and in steel with quinaldic acid. A. M. Zan'ko and G. O. Butenko. *Ber. Inst. physik. Chem., Akad. Wiss. Ukr. S. S. R.* **9**, 99–107 (1938); *Khim. Referat. Zhur.* **2**, No. 3, 73-4(1939) — The method is based on the relative unstability of the tartaric complex of Cu at a definite acidity of the soln. and on the fact that the quinaldate of Cu is less sol. than are the corresponding compds. of the other elements in steel and cast iron. For the analysis dissolve 1 g. of the metal in 15–20 cc. of 6 *N* HCl, acidify with 2–3 cc. of coned. HNO_3, boil for some time, evap. the soln. to dryness in a porcelain dish and sep. the SiO_2 by the usual method. Filter off the residue, roast it, treat it in a Pt crucible with HF + H_2SO_4 (until white fumes appear), ext. with water and add the soln. to the original filtrate. Add to the mixt. 6 g. of tartaric acid, neutralize to nitrazine yellow paper with NH_4OH, add 15 cc. of 4 *N* H_2SO_4, heat to boiling and ppt. (by stirring) with an excess of a 2% soln. of Na quinaldate. Let the mixt. stand (total vol. 100–120 cc.) for 18 hrs., filter through a glass crucible No. 3 or 4, wash the residue with hot water, dry at 125° and weigh. One g. of ppt. = 0.1494 g. of Cu. If the amt. of Cu in the sample is less than 0.05–0.06% take twice as much sample and twice the quantities of tartaric acid and of 4 *N* H_2SO_4. The Cu values obtained are accurate within 0.02% of the wt. of sample. W. R. Henn

A new method for the determination of copper in stereotype and linotype alloys. N. V. Fedorova. *Poligraficheskoe Proizvodstvo* **1938**, No. 8-9, 41-3; *Khim. Referat. Zhur.* **2**, No. 3, 71(1939).—F. recommends the colorimetric method of T. Carnelly (*Chem. News* **32**, 308 (1875)) for the detn. of Cu with $K_4Fe(CN)_6$ in the presence of NH_4Cl. W. R. Henn

New method for the gravimetric determination of tin in bronzes and brasses. A. G. Dunbar-Poole. *Analyst* **64**, 870, 3(1939).—The principle involved in the proposed method is based on the discovery that when Sn contg. P or As is ignited in the air in the presence of Cu, the P and As are taken up by the Cu to form phosphate and arsenate of Cu without the formation of any stannate A subsequent digestion with HNO_3 dissolves out the Cu, As and P and leaves purified SnO_2. For the analysis of bronze a 0.5-g. sample is usually sufficient but with brass about 2 g. is better. Digest the weighed drillings with a mixt. of 15 ml. 6 *N* HNO_3 and 5 ml. of 6 *N* HCl. After the metal has dissolved, dil. with water and add NH_3 soln. until a deep-blue color persists after stirring. Neutralize with 9 *N* H_2SO_4 and add 2 ml. in excess. Dil. with hot water to 300 ml. and, while boiling the soln., add 4 g. of $Na_2S_2O_3$ dissolved in 50 ml. of water. Boil gently for 15 min. The ppt. will contain all the Sn and Sb as hydrated oxides together with some adsorbed Cu. Filter, wash with very dil. $(NH_4)_2SO_4$ soln. and ignite. Transfer the ignited ppt. to a small beaker, cover with 25 ml. of coned. HNO_3 and digest until all Cu has dissolved. Dil. to 100 ml. and allow the ppt. to settle while the soln. is kept hot. Filter, wash with hot, dil. HNO_3, ignite and weigh as SnO_2. If the residue is white, no Sb is present. The presence of Sb causes the residue to assume a bluish tint and, if necessary, it can be fused with NaOH in a Ag crucible and a sepn. of Sb from Sn made. The results in the analysis of 4 alloys appear to be unusually good and the ignited oxides of SnO_2 + Sb_2O_4 in samples contg. Sb were apparently pure and contained all the Sb and all the Sn. W. T. H.

Determination of nitrogen as ammonia in monosubstituted ureas, urethans, allophanates and semicarbazones. Santiago Rovira. *Compt. rend.* **209**, 754 7(1939); cf. *C. A.* **34**, 345[9].—The use of a benzyl alc. soln. of KOH for detg. N of amides and nitriles requires in some cases an excessive period of heating, e. g., 4 hrs. for a semicarbazone. The use of a higher-boiling solvent, e. g., glycerol is therefore advantageous. The time necessary is thus reduced by more than half with no reduction in accuracy. Results with 24 substances were within 3% of the truth. C. A. Silberrad

Method for the accurate estimation of elementary sulfur dissolved in organic liquids. B. S. Rao and M. R. Aswathanarayano Rao. *Atti X° congr. intern. chim.* **3**, 462–5(1939)(in English).—The liquid is shaken with Hg under suitable conditions and then, out of contact with air, the HgS is treated with aq. HCl soln. contg. KI + H_3PO_2. This results in evolution of H_2S which is swept away, absorbed in an aq. suspension of $Zn(OH)_2$ and the resulting ZnS detd. iodometrically or, if the S content is very low, by the methylene blue colorimetric method. W. T. H.

Determination of ferrous oxide in liquid chromium-molybdenum steel. V. T. Braga. *Teoriya Prakt. Met.* **9**, No. 7–8, 55–7(1938); *Khim. Referat. Zhur.* **2**, No. 3, 75(1939).—A rapid gas method for the detn. of FeO in steel consists in the removal of the gases from the liquid sample by suction under a vacuum. These gases are analyzed for their content of CO and of other gases (CO_2 which is formed from 2CO = C + CO_2). The amt. of CO sepd. according to the reaction FeO + C → CO + Fe (1) multiplied by $^{72}/_{28}$ gives the amt. of FeO. This method (Hare, Peterson and Soler, *C. A.* **31**, 7816[1]) was tested on Cr-Mo steels fused in acid elec. furnaces. A

comparison of the results with those obtained by the method of Herty (reduction of FeO with metallic Al with the formation of Al_2O_3 followed by its detn.) proved the dependability of the method. The main requirement of the method is as complete as possible reduction of the metal. The sample should be completely liquid during its analysis. The time required for the sample taking is about a min. W. R. Henn

A simplified method for the calculation of the carbon dioxide content in air. L. I. Figlin. *Higiena i Sanitariya* **1938**, No. 2, 23–32; *Khim. Referat. Zhur.* **2**, No. 1, 70 (1939).—It is proposed to use nomograms. The necessary calcns. are described and several auxiliary tables are given. W. R. Henn

Determination of water in ether. R. Gaspart and G. Serrure. *Bull. soc. chim. Belg.* **48**, 283–92(1939); cf. *C. A.* **33**, 3296[1].—The infrared absorption spectra between 3400 and 3700 cm.$^{-1}$ are given for anhyd. ether fractionally distd. from Na through a 110-cm. Crismer column (all-glass app.) and for ether contg. 0.55, 1.45, 3.66, 5.00, 11.70 and 27.80 × 10^{-4} mols. of H_2O per l. (prepd. by dilg. 3 concd. solns. in carefully dried app.). The 1st 2 solns. show a single band at 3598 cm.$^{-1}$, the others a 2nd band at 3525 cm.$^{-1}$. The bands are attributed to H_2O-Et_2O addn. compds. The concn. of H_2O can be interpolated from a standard curve constructed with χ (extinction coeff.) plotted against concn. in mol. per l. The concn. of H_2O in colloidal Au solns. is detd. by this method with the formula $T = e^{-\chi d}$ where T is the value of the transmission at the min. 3598 cm.$^{-1}$. Janet E. Austin

The interferometer in the analysis of dilute solutions of strong electrolytes. A. M. Zan'ko and I. L. Kukhtevich. *Trudy Dnepropetrov. Khim.-Tekhnol. Inst.* **1938**, 33–59; *Khim. Referat. Zhur.* **2**, No. 2, 70(1939).—The possibility of using the interferometer for detg. the concn. of substances in aq. solns. is shown by a study of solns. of HCl, NaOH and Na_2CO_3 which were 0.001–0.160 *N*. The method can be used only for measurements of pure substances in soln. but is then more accurate than the usual methods of analysis. Details for carrying out the work are given. W. R. Henn

Identification of propionic acid in the presence of acetic and butyric acids. Louis Musicant and Frank J. Kaszuba. *J. Am. Chem. Soc.* **61**, 2974–6(1939).—Propionates can be identified in the presence of acetates and butyrates by prepg. photomicrographs of the mercurous salt; the salt is pptd. on a microscope slide from the Na salt and Hg$(NO_3)_2$; as little as 0.15 mg. can be positively identified. Formates should be destroyed before the test. C. J. West

Angular constants of microcrystalline profiles and silhouettes in the conclusive identification of substances. IV. R. C. Shank, M. D. Grimes and A. C. Shead. *Proc. Okla. Acad. Sci.* **19**, 127–9(1939); cf. *C. A.* **32**, 737.—Angular values are listed for 11 addnl. compds. W. F. Bradley

Dithizone colorimetric micromethod for the determination of lead. G. A. Evlanov. *Nauch. Zapiski Inst. Narodnogo Khozyaĭstva im. Plekhanova* **1938**, No. 1, 131–5; *Khim. Referat. Zhur.* **2**, No. 3, 71–2(1939).—The following colorimetric micromethod for the detn. of Pb is based on the method of Hellmut Fischer and Grete Leopoli (*C. A.* **28**, 2295[8]). To a soln. contg. Pb^{++} and Rochelle salt add NH_4OH in excess, and ext. in a separatory funnel several times with a soln. of dithizone in CCl_4. Treat the CCl_4 exts. with aq. KCN soln. to get the excess dithizone into the aq. phase. Wash the soln. of the pure dithizone compd., destroy the Pb complex with HCl (1:1) and after dilg. with more CCl_4, examine the green soln. in a Dubosc colorimeter. From the quantity of dithizone found the amt. of Pb combined with it is detd. The method can be used in the presence of the alkali and the alk. earth metals which do not give complexes with dithizone. The heavy metals (Zn, Ni, Fe, Cu, Hg, Bi, Sn, Ag) are converted into complex cyanides prior to the treatment on the dithizone. By this method 200 to 10 γ of Pb can be detd. which makes it suitable for *examn.* of *food products*. W. R. Henn

The semimicrodetermination of sulfur in organic materials. Antonio Angeletti. *Ann. chim. applicata* **29**, 356–9(1939).—The method is based on Sanchez method (*C. A.* **32**, 6577[1]) for the semimicrodetn. of halogens in org. compds. The S is oxidized in a sealed tube with $KMnO_4$, the sulfate formed is pptd. with $BaCl_2$ in slight excess, and this excess pptd., in turn, with K_2CrO_4 in slight excess. The excess K_2CrO_4, finally, is titrated iodometrically. A blank detn. on K_2SO_4 should be carried out as a check. A. W. Contieri

Semimicroanalytical method for the determination of methoxyl groups in organic compounds. E. B. Lisle *Analyst* **64**, 876–7(1939).—Satisfactory results can be obtained quickly by an adaptation of the Zeisel method for detg. CH_3O groups in org. compds. The group is removed as volatile CH_3I by the action of HI at 130° and the vapor is passed over test paper which has been steeped in a soln. of $PdCl_2$ and pyridine. A brown color results if CH_3O is present. Dissolve 0.5 g. of sample in a little decahydronaphthalene and dil. to 50 ml. Take a convenient aliquot and transfer to a 50-ml. flask fitted with a side tube and ground-glass neck. A glass tube, 18 cm. long of 0.7 cm. bore, fits into the neck of the flask and the top of this tube ends in a disk-like flange with ground surface. A similar glass flange rests on this surface and is attached to a glass tube 3 cm. long. The 2 flanges are held together by 2 steel clips. Place a strip of filter paper satd. with $PdCl_2$ and pyridine between the flanges. Conduct a slow stream of CO_2 through the app. Dry the CO_2 by passing it through glycerol and heating it to 35° by passage through a tube kept in hot water. Heat the contents of the reaction flask in an oil bath which is kept at 130°. Shake frequently. After 30 min. remove the test paper, allow to dry and compare with standards prepd. from known quantities of vanillin. The method was tested with anisole, eugenol and guaiacol and the values 28.0, 18.5 and 24.3% were obtained in place of the theoretical values 28.7, 18.9 and 25.0. W. T. H.

The application of micromethods to the analysis of zein. II. Tauno Laine. *Suomen Kemistilehti* **12B**, 23(1939)(in English); cf. *C. A.* **33**, 6359[8].—The results of microchemical analyses indicate that the N of zein is present as amino acids of which alanine alone constitutes 9.75%, alanine + valine + leucine + phenylalanine + methionine = 32.3%, aspartic acid = 2.22%, tyrosine = 2.61%, glutamic acid = 18.4% and cystine = 0.60%. The corresponding values obtained by macromethods are 9.56, 32.8, 1.18, 2.83, 18.5 and 0.66%. For the analyses the methods of Virtanen and L. (*C. A.* **33**, 505[9]), Arhimo and modified by Pucher (*C. A.* **33**, 6198[6]), Arhimo and L. (*C. A.* **33**, 6198[8]) and Brdicka (*C. A.* **29**, 82[4]) were used. S. A. Karjala

Biochemical study on lead. I. Quantitative analysis of very small amounts of lead in organic substances. Susumu Yosida. *Oriental J. Diseases Infants* **23**, 15–16(1938)(in English).—The Pb is sepd. electrolytically as PbO_2 in the presence of strong HNO_3 contg. Cu and analyzed polarographically. Other ions from org. substances, such as liver and bone, do not interfere. **II. The adsorption of lead ions by activated charcoal.** *Ibid.* **24**, 9. The extent to which Pb ions are adsorbed by charcoal is shown to vary considerably with different kinds of charcoal. Ruth Berggren

A rapid analysis of crude and of enriched anthracene. I. Ya. Postovskiĭ and V. I. Khmelevskiĭ. *Trudy Ural. Ind. Inst. im. S. M. Kirova* **1938**, No. 6, 64–9; *Khim. Referat. Zhur.* **2**, No. 2, 85(1939).—The method is based on the addn. of maleic anhydride to anthracene. The compd. formed can be detd. either directly by the gravimetric method or indirectly by the volumetric titration of uncombined maleic anhydride. To 1 g. of the crude anthracene add 0.5 g. of maleic anhydride and 5 cc. of xylene, boil for 25 min., add 80 cc. of water, remove the xylene with steam, cool the maleic acid (formed at the expense of the emulsification of the excess anhydride), and titrate with a 0.5 *N* soln. of KOH in the presence of phenolphthalein. The method was tested with artificial mixts. of anthracene with carbazole, phenanthrene, fluorene, ace-

naphthene and β-methylanthracene. Of these substances only β-methylanthracene reacts with maleic anhydride. Therefore, in case β-methylanthracene is present a parallel detn. by the method of Sielisch should be made. The analysis takes 1–1.5 hrs., and its accuracy is ± 0.5%.
W. R. Henn

A new method for the determination of carbazole and anthracene in crude and in concentrated anthracenes by the bromometric method. B. I. Ardashev. *Trudy Ural. Ind. Inst. im. S. M. Kirova* **1938**, No. 6, 70–9; *Khim. Referat. Zhur.* **2**, No. 3, 83(1939); cf. *C. A.* **32**, 1612⁸. — The method is based on the bromination of carbazole to form the dibromide. Anthracene, which is usually present in the crude product, is also brominated, but its content can be detd. in parallel detns. by the method of Postovskiĭ and Khmelevskiĭ (in the form of the condensation product with the maleic anhydride). From the other substances present together with carbazole only acenaphthene can be brominated, but it is rarely present in appreciable quantities. In checking the method on artificial mixts. of anthracene, phenanthrene and carbazole the percentage error in some cases reached 5%. With a parallel detn. of N according to the method of Kjeldahl the content of other N compds. can be estd. The time required for the analysis of samples contg. only anthracene and carbazole is 1 hr. The procedure is as follows: Dissolve 0.5 g. of the sample in 15–20 cc. of a hot 80–90% soln. of AcOH, add 1–1.5 cc. of 12 *N* HCl, cool to 35° and add at this temp. an accurately measured vol. of a standardized soln. contg. 16.72 g. of $KBrO_3$ and 59.5 g. of KBr in 1 l. Add the bromide-bromate soln. until the reaction to a I-starch paper persists for 10 min. After this add a soln. of 0.5 g. of KI in 25 cc. of water and titrate the sepd. I with $S_2O_3^{--}$ to dct. the excess $KBrO_3$.
W. R. Henn

Determination of paraldehyde. D. J. T. Bagnall, A. Smith and A. R. Tankard. *Analyst* **64**, 857–61(1939). The following procedure is recommended in cases of suspected poisoning after the administration of paraldehyde. Place 50 g. of minced material in a l. flask and add 100 ml. of 50% EtOH + 1 2 ml. of concd. H_2SO_4. Adjust a fractionating tower to the flask and connect it with a good condenser dipping into a 4% soln. of neutralized NH_2OH.·HCl in 50% alc. About 10 ml. of this soln. is required for 0.2 g. of paraldehyde. Heat the mixt. in the flask gently at first and distil slowly with steam. After at least 100 ml. of distillate has been obtained, titrate with NaOH to a green end point with bromophenol blue indicator. Then distil some more into the titrated soln. and consider the reaction complete if no change in color takes place after 50 ml. more of distillate has been obtained. One ml. of 0.1 *N* NaOH = 4.4 mg. of paraldehyde. Carry out a blank test in the same way. Stomach contents, viscera, etc., usually contain small quantities of volatile acids and these must be allowed for by a sep. distn. in the presence of H_2SO_4.
W. T. H.

Creatinine determination with *m*-dinitrobenzoic acid. Ernst Komm and Heinz Pinder. *Z. Untersuch. Lebensm.* **78**, 113–23(1939).—The utility of *m*-dinitrobenzoic acid as a reagent for the detn. of creatinine was confirmed. Tests on the stability of the reagent, effect of impurities, amts. of reagent and means of decolorizing samples were made for the development of the following procedure: Free a 5% meat soup soln. or a 0.5% meat ext. soln. from fat. Add 20 cc. *N* HCl to 50 cc. of sample in an evapg. dish and evap. to dryness on a steam bath. Take up the residue with water and dil. to 50 cc. in a volumetric flask. Filter with suction through a column of $Al(OH)_3$, 3 cm. diam. and 10–15 cm. high (cf. Remy, *C. A.* **32**, 1213⁶). To 20 cc. of the filtrate add 5 cc. *N* HCl and dil. to 50 cc. with distd. water. Treat 2.00 cc. of the soln. with 4 cc. of 2% *m*-dinitrobenzoic acid in abs. alc. and 1 cc. of a 5% soln. of NaOH in water. Treat similarly a 0.01% standard creatinine soln. in 0.1 *N* HCl with the reagent and NaOH soln. Measure the percentage absorption in a photoelec. colorimeter or compare the 2 solns. in a Dubosq colorimeter.
M. M. Piskur

Phthalization in hot pyridine. Sébastien Sabetay. *Ann. chim. anal. chim. appl.* **21**, 289–90(1939); cf. *C. A.* **31**, 2550⁶.—In the previous paper, a method for detg. primary alcs. was proposed which consists in heating with phthalic anhydride at the b. p. of the alc. for 2 hrs. under reflux condensation after which a definite vol. of water is added and some pyridine. After this the mixt. is titrated with NaOH. Under the prescribed conditions good results can be obtained. Some chemists have encountered difficulties arising from a partial sapon. of the acid phthalate ester that is formed in the procedure. Incorrect results are obtained if the heating is continued for 20 min. instead of the prescribed 10 or if 20 ml. is the vol. of the soln. during the pyridine treatment instead of the prescribed 50 ml. The hydrolysis of the excess phthalic acid is accomplished within 1 min.
W. T. H.

Qual. org. analysis—identification of alkyl halides, aromatic nitroso compds., aromatic hydrocarbons and cyclopentadiene compds. (Levy, Campbell) **10**. Detn. of S in solid fuel and in pyrite (Seuthe) **21**. Behavior of the SCH_3 group in methoxyl detns. (Arndt, *et al.*) **10**.

Determination of constituents such as hydrogen sulfide in gaseous atmospheres. John B. Littlefield (to Mine Safety Appliances Co.). U. S. 2,174,349, Sept. 26. A method of detg. the concn. of a constituent of a gaseous atm. comprises causing a predetd. volume of the atm. to be tested to flow through an elongated bed of granular material carrying a salt reagent which upon contact with the constituent changes color over a length which is dependent upon the concn. of the constituent in the atm., the color change being substantially independent of the concn. of the constituent and measuring the length. Ag cyanide is used in detg. the concn. of H_2S.

8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

ARTHUR M. BRANT

Germanium in some sulfide ores in U. S. S. R. S. A. Borovik and N. M. Prokopenko. *Bull. acad. sci. U. R. S. S., Sér. géol.* **1938**, No. 2, 341–6; *Khim. Referat. Zhur.* **2**, No. 1, 29(1939); cf. *C. A.* **33**, 4549⁸.—Ninety-three samples of sulfide minerals from Middle Asia (mostly), Baĭkal region, Ural, Caucasus, Ukraine, and the northern part of the European U. S. S. R. were analyzed spectrographically. Of 58 sphalerites, 19 contained Ge in small amts. Zn blende contg. Ge is as a rule light-colored and is characterized by a very small amt. or total absence of In. Sphalerites contg. Ge are mostly found with low-temp. meso- and epi-thermal deposits. The Middle Asia sulfide deposits contain little Ge. In zones of oxidation no Ge was found. Ge was found in small amts. in Zn blende from Caucasus, Ural and the Northern regions. Other investigators found Ge in sphalerites from Medvezh'iĭ, Azerbaĭdzhan and Ridder, as well as in some chalcopyrites from Caucasus, Ural and the Minusin region.
W. R. Henn

Iron oxide monohydrate (goethite). Hans Himmel. *Zentr. Mineral., Geol.* **1939A**, 281–6.—Crystallographic. It is suggested that goethite and lepidocrocite, α-FeOOH and γ-FeOOH, resp., be called α-goethite and γ-goethite.
Michael Fleischer

Alteration of ilmenite. E. S. Moore. *Econ. Geol.* **34**, 931(1939); cf. Koenigsberger, *C. A.* **34**, 58⁴.—M. agrees with K. that leucoxene is derived from ilmenite in most cases by hydrothermal action, not by weathering. However, leucoxene is not always titanite, but may consist of several Ti minerals.
Michael Fleischer

Microstructure and origin of the Wittekind horizon. G. Berg. *Z. prakt. Geol.* **47**, 175–80(1939).—Sixteen drill

cores in an oölitic ironstone horizon in the Upper Dogger near Hüverstädt were studied. The material was originally a marl with oölites of an Fe silicate near chamosite. Bicarbonate solns. changed the silicate almost completely to siderite. Michael Fleischer

The rare earth content of wiikite. Th. G. Sahama and Veikko Vähätalo. *Bull. comm. géol. Finlande* No. 125, 97–109(1939)(in English); cf. Lokka, *C. A.* **22**, 4416; Ant-Wuorinen, *C. A.* **31**, 1732[9].—Spectrographic detns. are given of the content of 16 rare earth elements in 6 wiikites. Y predominates, and the ratio Y earths:Ce earths is high, usually 6 to 10. Samples of *allanite* and *monazite* were also examd.; Ce earths predominate in these. Michael Fleischer

Arseniosiderite from Hüttenberg, Carinthia. Heinz Meixner. *Zentr. Mineral., Geol.* **1939A**, 287–9.—Arseniosiderite occurs as a brown "mountain leather" with symplesite and scorodite, all formed by the oxidation of löllingite. Michael Fleischer

Use of explosives in synthesis of deep rock minerals. Albert Michel-Lévy. *Compt. rend. soc. géol. France* **1939**, 194–6; cf. *C. A.* **34**, 576.—A connected account of later results already briefly reported (cf. *C. A.* **33**, 7699[1]) showing that at temp. of 500–600° and pressures of 3000–4000 kg./sq. cm. in presence of H_2O and alkali—conditions which occur at depths of 10,000–20,000 m.—the principal minerals of granite are formed; also that under these circumstances circulating fluids of this nature produce changes in actual rocks similar to actually observed metamorphism. C. A. Silberrad

Gases in mineral salts. Yu. V. Morachevskii. *Byull. Inst. Halurgii* **1938**, No. 5, 1–14; *Khim. Referat. Zhur.* **2**, No. 3, 25(1939). By measuring the evolved gases (present as microdispersed inclusions in different layers of salts composing the Solikamsk formations) it has been shown that the many-colored sylvite is the richest in gas content (50–100 cc. per kg.), followed by the striped and the red sylvites. Carnallite usually contains about 10 cc. of the microincluded gas per kg. of the salt, and very little gas was contained in the halite. Large variations in the gas content were observed in the different samples of the same layer. The gases differ in compn.; they can be classified into 4 types depending on their relative contents of H_2, CH_4, N_2 and heavy hydrocarbons (from 1 to 6%). The formation of the combustible components in the included gases (CH_4 and H_2) is attributed mainly to processes of a biochem. character. W. R. Henn

Gold in Alsace-Lorraine. E. Kohl. *Z. prakt. Geol.* **47**, 180–4(1939).—A review with 15 references. Prospects of finding any appreciable amt. of Au are considered poor. Michael Fleischer

Minerals of Kivu (Belgian Congo.) René van Aubel. *Compt. rend. soc. géol. France* **1939**, 186–8; cf. *C. A.* **31**, 3428.—Three polished sections and 2 powd. samples of auriferous quartz from Kivu were examd. The sections showed about 10% tourmaline; the other principal components in order of abundance are quartz, mispickel (I), pyrite (II) and hypogene Au, with subordinate amts. of magnetite (III), pyrrhotite (IV), chalcopyrite (V), hematite and marcasite (VI) but no telluride. The order of formation appears to be III, IV, I, II, V and VI, thus differing from Schwarz's rule (*C. A.* **31**, 2556[6]). The powd. samples are also minutely described. They indicate formation at a high temp., and probably at considerable depth (cf. Buddington, *C. A.* **30**, 3747[7]). C. A. S.

The pyrite deposit of Hevoskumpu in Tuupovaara. Erkki Aurola and Veikko Vähätalo. *Bull. comm. géol. Finlande* No. 125, 87–95(1939)(in English).—The ore body of pyrite and pyrrhotite is bordered by a zone of epidote-quartzite on one side, and by a zone of sericite-quartzite on the other. These were probably formed by the metasomatic action of the ore-bearing solns., rich in carbonates and sulfides, on the country rock, an amphibolite. The deposit is very similar to that at Otravaara nearby (cf. Saxén, *C. A.* **18**, 1634). Michael Fleischer

Magnetite and hematite veins in Triassic lavas of Nova Scotia. A. P. Hornor, Jr. *Econ. Geol.* **34**, 921–30(1939).—The veins, occurring in basaltic lavas, were probably formed by the filling of fissures by emanations from the cooling lavas. The order of crystn. was hematite and magnetite with some apatite, calcite, zeolites and quartz. A complete analysis of the magnetite shows 6.42% MgO; hence it is intermediate between magnetite and magnesioferrite. Michael Fleischer

Some iron ores in the Jussaari region, S. W. Finland. Martti Saksela. *Bull. comm. géol. Finlande* No. 125, 9–38 (1939)(in German).—The banded Fe ores, found on several small islands and also extending under water between them, contain magnetite with quartz, amphibole and garnet. In places, magnetite and garnet have crystd. simultaneously. Late pegmatitic solns. rich in Fe appear to have migmatitized schists and simultaneously deposited magnetite. A brief history of mining operations, now abandoned, is given, with several ore analyses. Most of the ore carried 30–35% Fe. Michael Fleischer

An occurrence of tinstone in the Pre-Cambrian of western Ontario. E. M. Burwash. *J. Geol.* **47**, 767–8(1939). Cassiterite has been found in narrow greisen dikes near Eagle Lake. Similar occurrences have been noted in eastern Manitoba, and a tin-bearing area of some size is indicated. Michael Fleischer

Coal veins in Malaya. Sir Lewis L. Fermor. *Geol. Mag.* **76**, 465–72(1939); cf. *C. A.* **24**, 1488; **25**, 578.—F.'s views on the colloidal nature of coal and its formation are recapitulated, and strongly supported by recent observations in Malaya of a vertical vein of vitrain about 4½" thick of which analyses of the outer, intermediate and central portions are given as also the values of k in F.'s formula, ash content = $100(d - k)$, (d being density). These show increases in k and moisture, and decreases in volatile matter and fixed C from the center outward. Conclusion: Org. matter, derived from wood (occurring as such elsewhere in the surrounding alluvium), passed into colloidal soln. whence it was deposited in the vein by gelation. C. A. Silberrad

Geology of western Quruq Tagh, eastern Tien-Shan. Erik Norin. *Rept. Sci. Exped. to N. W. China* **1937**, 195 pp.; *Neues Jahrb. Mineral. Geol.*, Ref. II, **1939**, 522.—Detailed petrographical descriptions of the rocks found are given. C. A. Silberrad

The crystallization of the Kangasniemi orbicular granite. D. S. Belyankin and V. P. Petrov. *J. Geol.* **47**, 769–71(1939).—Discussion of Eskola's conclusions (*C. A.* **32**, 6195[7]). Michael Fleischer

Petrology of the alkaline intrusive at Blue Mountain, Ontario. M. L. Keith. *Bull. Geol. Soc. Am.* **50**, 1795–1826(1939).—A large stock of alk. rocks, previously described as nephelite syenite, is more accurately a litchfieldite, the mean of 112 Rosiwal analyses giving albite 54, microcline 20, nephelite 22, muscovite 2 and mafic minerals 2%. The mineralogical variations are shown on contoured distribution plans. Age detns. based on radioactivity measurements give 850 ± 400 million yrs. for the litchfieldite, 150–200 ± 75 million yrs. for the surrounding syenodiorite. This precludes the possibility of a genetic relationship between them, and with the lack of field evidence of desilication by limestone, renders the theory of limestone assimilation untenable for this intrusive and probably for the Bancroft area. Field evidence indicates that the litchfieldite crystd. from an alk. magma with a compn. close to that of the av. of the intrusive, the relations approximating those in synthetic melts (cf. Bowen, *C. A.* **31**, 1734[6]). Five rock analyses and analyses of albite, nephelite and microcline are given. M. Fleischer

Geochemical properties of the Maarianvaara granite. Th. G. Sahama and Kalervo Rankama. *Bull. comm. géol. Finlande* No. 125, 5–8(1939)(in English).—A preliminary note. It is hoped that the spectrographic detn. of minor constituents will make possible the classification of the Finnish Archaean granites into provinces showing similarities in their content of the rarer elements. Qual. data indicate that the rare earths, Sr, Ba, Cr and V may be suitable index elements. Michael Fleischer

The rock ground of the coast of Labrador and the connection between the Pre-Cambrian of Greenland and

North America. E. H. Kranck. *Bull. comm. géol. Finlande* No. 125, 65–86(1939)(in English).—Rock types of the Labrador coast are described and tentatively correlated with those of Greenland. New analyses are given of nordmarkite, odinite, and *aillikite*, the last being an alnoite-like dike rock, high in olivine, biotite and calcite.
Michael Fleischer

Metasomatism associated with Tertiary mineralization in New Guinea. N. H. Fisher. *Econ. Geol.* **34**, 890–904 (1939).—Porphyries and phyllites of the Wau-Edie Creek area have been metasomatized over a considerable area to soft, easily eroded rocks such as chloritoid schist. This has led to considerable placer enrichment in Au.
Michael Fleischer

Formation and age of the Syrian green rocks. Lois Dubertret. *Compt. rend.* **209**, 763–4(1939); cf. *C. A.* **31**, 6153⁷.—These rocks are further described; the peridotite-pyroxenite extends practically uniformly for a depth of some 1800 m. In places it passes with no distinct boundary into masses of microdiorite, which become more and more fine-grained upward and finally vitreous with pillow lavas and volcanic tuffs and breccias. In places large blocks of much altered sedimentary rocks (Trias to Cretaceous) are included. The formation appears to have resulted from a combination of igneous intrusions at great and moderate depths with actual volcanism. C. A. Silberrad

Rock formations of Middle Asia. I. M. Evfimenko. *Razvedka Nedr* **1938**, No. 8–9, 12–16; *Khim. Referat. Zhur.* **2**, No. 1, 28(1939).—The following geochem. classification of rocks is given: magnetite rocks (Tan-Shan type), pyrrhotite rocks (Alaĭ type), and rocks without pyrrhotite and magnetite (Nur-Atin type). The magnetite rocks often contain hematite and industrial amts. of chalcopyrite. Other sulfides may be present as well as cobaltite and erythrite. Scheelite is absent. The pyrrhotite Alaĭ type contains much arsenopyrite. Little magnetite is present. Scheelite, cassiterite, molybdenite and minerals of Co and Bi are present. These rocks are characterized by 2 stages of mineral formation: the contact stage (formation of the garnet-pyroxene rocks) and the pneumatolitic stage (addn. of W, Sn, Mo and other elements). The Nur-Atin type (contg. no Fe) is related to the garnet-pyroxene types. Scheelite and molybdenite are present. This type contains much WO_3. W. R. H.

Limestones of Ardgour (Argyllshire). H. I. Drever. *Geol. Mag.* **76**, 501–18(1939); cf. *C. A.* **30**, 8102⁴.—These limestones have been much altered by high-grade metamorphism—dynamic or thermal or both—owing to epidioritic intrusions and metasomatic action of solns. of uncertain origin. They are classified according as they are assocd. with granulites and quartzites, diorite gneiss or serpentine. Much wollastonite, also prehnite and scapolite have been formed, also several zeolites and other minerals. Contact effects have also been produced in the intrusive rocks owing to contamination by the limestone, but to a smaller extent. The petrology of the occurrences and the probable metamorphic processes are minutely described with several photomicrographs and 33 references.
C. A. Silberrad

Electromagnetic separator for mineral powders (Evans 1.

9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, OSCAR E. HARDER AND RICHARD RIMBACH

Sixty years of development in ore dressing with special attention to the last ten years. C. S. Parsons. *Can. Mining J.* **60**, 693–711(1939). W. H. Boynton

The content of dispersed rare earth elements thallium, indium, gallium and germanium in the intermediate and the waste products of the nonferrous metallurgy of Ural. V. S. Syrokomskiĭ and A. K. Sharova. *Tsvetnye Metal.* **1938**, No. 11, 23–7; *Khim. Referat. Zhur.* **2**, No. 3, 93–4 (1939).—There were found in the intermediate and the waste products of the nonferrous metallurgy of Ural, in most cases, increased amts. of Tl, Ga and Ge. This is explained by the fact that they are contained in the ores of the nonferrous metals in the form of isomorphous admixts. and that a natural concn. of these elements takes place during the process of the technological treatment of the ore. W. R. Henn

Rare metals in the Bashkir republic. I. E. Leshchuk. *Zolotaya Prom.* **11**, No. 7, 18–19(1939).—A short description of the distribution of Se, Te, Bi, Sb, Cd, In, Co, V, As, Sn, Pt, Os, Ir, W, Ce, Th, Zr and Hg in the Bashkir republic of the Soviet Union. B. Z. Kamich

The composition and the properties of cyanide slimes. A. I. Gaev, T. S. Dolzhenko, E. V. Serebrova and P. V. Trutnev. *Tsvetnye Metal.* **1938**, No. 11, 76–80; *Khim. Referat. Zhur.* **2**, No. 3, 94(1939).—The chem. compn. of cyanide slimes from different plants varied greatly. Hygroscopicity was one of their characteristic properties. The presence of sol. sulfates and of CaO increased the hygroscopicity and the velocity of water absorption. The effect of SiO_2 on the hygroscopicity depended on the temp. of drying and roasting. A more thorough washing is necessary in order to lower the hygroscopicity. Results of the chem. and the sieve analyses are given as well as tables and graphs which characterize the hygroscopicity of different slimes. W. R. Henn

Concentration of Artemovsk pyrrhotites. A. G. Bayula. *Zolotaya Prom.* **11**, No. 4–5, 38–40(1939).—Flotation of Artemovsk pyrrhotites yielded concentrates contg. 93–95% of the Au content of the ore. Conditions of flotation were: CaO 0.5–1.0 or soda 2 kg., sol. glass 0.5 kg., xanthate 0.05 kg. and pine oil 0.016 kg./ton. Duration of agitation with reagents ~12 min., flotation ~15 min., liquid/solid ratio 4:1. The flotation products consist chiefly of sulfides contg. small amts. of Cu, Co, Zn and As. Na_2SO_3 did not act as a selective depressor of pyrrhotite. With lime the extn. of Au was 93% and with soda 97%.
B. Z. Kamich

The Stuerzelberg process. H. Hofmeister. *Mining J.* (London) **206**, 757–8(1939).—This process was developed to handle low-grade ores in Germany, especially those contg. PbO, ZnO and other impurities unsuited to usual blast-furnace operation. It can operate with low-grade solid fuel when high-quality coke is unavailable although it cannot compete with large blast-furnace operations except where unusual conditions exist. Starting with calcined pyrites contg. Fe 44, SiO_2 10.2, S 5.0, Zn 8.2, Pb 0.4, Mn 0.2, P 0.02, As 0.02 and Cu 0.02%, a pig iron of the following analysis can be made: C 4.4–4.8, Si 0.015, Mn 0.2–0.4, P 0.01–0.03 and S below 0.01%. By means of a waste heat exchanger, the mixt. of ore, coal and lime is preheated and then charged into a rotary furnace where it is heated to 1500° to form a pasty ferrous silicate slag and spongy iron. The typical slag contains SiO_2 27, Al_2O_3 5, CaO 57, MgO 3–5 and Fe 2–4%. A. George Stern

Thirty years of zinc-blende roasting. Aladár Pór. *Mining J.* (London) **206**, 777–8, 795–6(1939).—A review.
A. George Stern

Pig-iron manufacture in a rotary cement kiln. Hisayuki Ohara. *Tetsu-to-Hagane* **25**, 831–42(1939).—In an exptl. process with purple ore there was obtained in the rotary cement kiln a pig iron contg. C 4.42, Si 0.09, Mn 0.11, P 0.069, S 0.009 and N 0.0023%. M. Ishida

Sulfide inclusions from clay packing. Geo. K. Manning. *Metal Progress* **36**, 747–8(1939).—A description of sulfide inclusions which formed in carburized parts from Al sulfate in packing clay. W. A. Mudge

Failure of press tools under fatigue and impact. C. E. Bretney. *Metal Progress* **36**, 751–4(1939).—The importance of design and the proper selection of materials are discussed. W. A. Mudge

Metallographic identification of ferromagnetic phases. H. S. Avery, V. O. Homerberg and Earnshaw Cook.

Metals & Alloys **10**, 353–5(1939).—If the polished surface of a metallographic specimen is covered with a thin colloidal suspension of magnetic particles, application of a magnetic field will cause a visible concn. of the colloid over the magnetic areas, and a characteristic mosaic pattern frequently results. This technique has proved especially useful for the detn. of ferrite in austenitic Ni-Cr-Fe alloys, and examples showing typical results for 3 different alloys are described. 8 references. I. Hartmann

Selection of greases for cold-rolling metals and alloys. I. M. Pavlov and Ya. S. Gallaĭ. *Kachestvennaya Stal* **6**, No. 2, 34–42(1938).—A discussion of the important requirements of greases for use in rolling metals and alloys. Results are given of lab. tests with various greases. The most satisfactory greases are those made of mineral and vegetable oil and also oil emulsions. The general requirements of such greases are sufficient viscosity and adhesiveness, no corrosion, stability, safety, ease of application and economy. The most effective oils are castor oil, vegetable oils, mineral oils, emulsions and kerosene in decreasing order. Effectiveness of greases is improved by the addn. of free fatty acids. B. Z. Kamich

Controlled atmospheres for heat-treatment of copper. Ralph D. Hawkins. *Gas* **15**, No. 12, 35–6(1939).—Flue gases are used as the furnace atm., sufficient vol. being circulated to prevent air infiltration. Flue products, cooled and dried, are also used in the cooling chamber. Cl is used for pickling Cu wire prior to tinning. R. W. Ryan

Stepwise heat-treatment of chromansil. I. M. Gryaznov and M. I. Yudkevich. *Aviapromyshlennost* **1939**, No. 6, 50–2.—Usual chromansil steel specimens were subjected to ordinary quenching in oil followed by tempering and to stepwise quenching and tempering. The mech. properties of the heat-treated specimens were then detd. and on the basis of these tests the following method is suggested: heating to normal temp., hardening in a mixt. of salts at 160–180°, and subsequent tempering to the required hardness. B. Z. Kamich

Industrial gears for large transmissions. Edward J. Wellauer. *Metal Progress* **36**, 725–30(1939).—The requirements for large, industrial gears, especially high-speed gears for transmitting large amts. of power, such as rolling mill drives or reduction units between steam turbines, are given. The relative merits of plain and alloy steels in forgings and castings are included. W. A. M.

Tempering of cast iron. Otto Glaser. *Giesserei* **26**, 466–7(1939).—Piston rods made from elec. furnace gray iron, chilled castings (3.1–3.3 C, 1.8–2.4 Si, 0.5 Mn, 0.6–0.8 P and 0.1 S) showed a 2–3-mm. white rim, consisting of fine-grained graphite, finely laminated pearlite, ferrite and phosphide eutectic. After annealing and machining, the castings were quenched from 850° in oil. Hardening increased the Brinell hardness from approx. 180 to 420. During heating for tempering, some of the graphite enters soln., forming γ mixed crystals; on quenching it becomes a martensite or martensitic-troostite. The martensite is fine acicular grained; the troostite forms dark spots, owing to the phosphide eutectic. The increased hardness is accompanied by an increase in wear resistance. Uniform dispersion of the phosphide eutectic gives reduced wear. F. W. Fink

Mechanical properties and creep resistance of steels for use in equipment for ammonia synthesis. N. A. Minkevich and A. M. Borzdyka. *Kachestvennaya Stal* **6**, No. 1, 8–18(1938).—Data are given for metallographic characteristics, mech. properties at normal and high temps., creep resistance, and heat resistance of 5 steels for use in equipment for ammonia synthesis. The steels were 2.5% Cr-Mo, 5% Cr-Mo, 5% Cr-Mo-V, 1.5% Cr-Cu and 2.5% Cr-Ti. The steels were prepd. in an acid induction furnace. Grain sizes (A. S. T. M.) were 4, 5, 8, 3 and 5, resp. The creep tests lasted up to 48 hrs. The highest creep resistance was shown by the Cr-Ti steel. It also had the greatest resistance to scale formation at temps. up to 1000°. But its impact toughness was rather low at normal temps. The 3 Cr-Mo steels had rather high and nearly the same creep resistance (stress of 17.4–19 kg./sq. mm. at 400° and 11–11.5 kg./sq. mm. at 500° corresponding to tangential creep of 10^{-6} mm./mm. per hr. in the interval of 24–48 hrs.). At 600° the oxidation of all steels was negligible and not over 0.05 mg./sq. cm. per hr., at 700° it was 0.2 mg./sq. cm. per hr., at 800° it was 0.9 mg./sq. cm. for all 3 Cr steels, 0.74 mg./sq. cm. for Cr-Cu steel, 0.54 mg./sq. cm. for the Cr-Ti steel, and at 900° the oxidation proceeded intensively. B. Z. K.

Transformation of austenite in fast-cutting steels. I. P. Lipilin and A. Usov. *Kachestvennaya Stal* **6**, No. 2, 14–18(1938).—A study was made of the effects on the transformation of supercooled austenite by various factors such as original structure, temp. of initial heating, speed of cooling from initial temp. to temp. of isothermic transformation, and plastic deformation above Ac_1. The following steels were tested: (1) C 0.70, Cr 4.34, W 18.50 and V 0.50%, and (2) C 0.35, Cr 2.55, W 7.70 and V 0.37%. In forged and rolled steel the transformation of supercooled austenite is more rapid than in cast steel owing to the presence of many finely dispersed carbides. By increasing the temp. of initial heating the stability of the supercooled austenite increases sharply owing to the soln. of carbides as well as to the increase in austenite grain size. A gradual cooling from the temp. of initial heating to the temp. of transformation decreases the stability of the supercooled austenite. Plastic deformation of the austenite before the transformation in the subcritical temp. region decreases the stability of the austenite. B. Z. K.

Effect of grain size of steel on the depth and hardness of the nitrided layer. L. I. Dmitriev and V. A. Lobacheva. *Aviapromyshlennost* **1939**, No. 4, 34–6.—Steels having A. S. T. M. grain sizes of 3, 4, 5 and 7 and contg. C 0.30–0.38, Cr 1.35–1.47, Mo 0.42–0.60, and 0.98–1.37% Al were nitrided at 520° (15 hrs.) + 580° (10 hrs.) in the presence of a catalyst after they were quenched at 940° in water and tempered at 630°. The depth of the nitrided layer decreased with increasing grain size while the hardness increased. For grain sizes of 3 to 7 the hardness varied from 76 to 85 Rockwell units (P-30) and the depth of the layer from 0.43 to 0.80 mm. for the same heat-treatment. B. Z. Kamich

Effect of phosphorus and arsenic on dynamo and transformer steel. V. S. Mes'kin and Yu. M. Margolin. *Kachestvennaya Stal* **6**, No. 3, 23–30(1938).—P shows a prolonged pos. effect on magnetic properties of dynamo steel contg. 0.8–1% Si with a rapid drop in the coercive force being observed for 0.2–0.25% P. For this P concn. the mech. properties of the steel are still good. P has no effect on magnetic properties of transformer steel. It raises the brittleness in proportion to the Si content. Arsenic does not compensate for the effect of P on brittleness. B. Z. Kamich

Effect of aging on the properties of Bessemer rail steel. I. Daĭkhes. *Novosti Tekhniki* **1938**, No. 24, 11–12.—Bessemer rail steel contg. C 0.43–0.45, Mn 0.75–0.95, S 0.04–0.059 and P 0.070–0.080% was subjected to artificial aging and the mech. properties were detd. The mech. properties as shown by rupture tests were not affected noticeably. The impact toughness was found to depend upon the temp. and duration of tempering. B. Z. K.

Tool steels. H. B. Chambers. *Can. Metals Met. Inds.* **2**, 270–3(1939).—All tool steels are classified into 12 groups with these arranged according to the combination of wear resistance and toughness, together with the conditions which they are required to meet. The properties of the steels in each group are indicated graphically for toughness, wear resistance at room temp., wear resistance at red hardness and movement in hardening. W. H. B.

Steel for aviation valves. M. V. Pridantsev and E. A. Klausting. *Kachestvennaya Stal* **6**, No. 1, 18–24(1938).—A study was made of the properties and heat-treatment of steel contg. C 0.45, Cr 17.36, Ni 6.5, Si 0.4 and Mn 0.4% and having unstable austenite. The optimum heat-treatment is: (1) temp. interval of hot mech. treatment—1050–800°, (2) heat-treatment of valves—tempering at 800°. Such steel gave $\gamma \rightleftarrows \alpha$ transformation, $\gamma \rightarrow \alpha$ starting at 150° and $\alpha \rightarrow \gamma$ taking place at 650–720°. The steel had a high hardness (350–400 Brinell units) and high

resistance to dynamic crumpling in the interval 20-900°. The coeff. of expansion of the steel was 12×10^{-6} against 16×10^{-6} for austenite steels. The steel is suggested for use as aviation valves. B. Z. Kamich

Low-carbon steels of high strength. K. Antipov. *Novosti Tekhniki* **1939**, No. 8 9, 21-2.—A study was made of the mech. properties of rolled, forged and simple heat-treated specimens of low-C steels contg. C 0.09-0.29, Si 0.06-1.03, Mn 0.35-1.32, Cr 0-1.12, Cu up to 0.61, Ni up to 0.10, P 0.014-0.169 and S 0.012-0.026%. Cu had very little effect on the mech. properties. With a low Si content the yield point and ultimate rupture strength drop considerably. By increasing the Mn content of P steels to 0.7-1.0% and over the steel becomes brittle. P steels should have over 0.15% C when the P content is 0.12-0.14%. Steels which satisfy these compn. requirements will have high mech. properties only if they contain also Si and Cr in amts. of 0.8-1.1%. B. Z. Kamich

Creep of some chromium-molybdenum steels. H. D. Newell. *Metals & Alloys* **10**, 342-5(1939).—The high-temp. creep properties of 5% Cr steels contg. 1 to 1.5% Mo were investigated to det. whether the increased Mo content provides any improvement over the common approx. 0.5% Mo alloy. Si was increased somewhat also, to increase the oxidation resistance. The results indicate that while the higher percentage Mo steels have slightly better resistance to creep throughout the temp range studied (538 to 649°), there is not sufficient difference in stress values to justify the increased cost of the addn. over the usual 0.5% Mo addn. I. Hartmann

Aluminum-iron alloys for bearings. P. S. Banas. *Aviapromyshlennost* **1939**, No. 3, 34 9.—Al-Fe alloy contg. 6% Fe and 0.5% Mg and possessing properties suitable for bearings in aero engines are best prepd. by centrifugal casting at 810-840°. After pouring, the metal should be cooled intensively to obtain a fine grain and to eliminate liquation of the Fe compds. The Fe should be introduced into the alloy directly or in the form of an Al-Fe alloy contg. 15-20% Fe. The alloy should be forged or pressed to improve its structure. Forging should be done at 500-550°. The material was suitable for bearings in aero engines and in Diesel engines. B. Z. Kamich

Casting and pressure treatment of aluminum-iron alloys. O. E. Kestner. *Aviapromyshlennost* **1939**, No. 6, 38-49.—The most suitable temp. for casting Al alloy contg. 6% Fe was found to be 860-880° followed by heating of the chill at 100° and then cooling with water. In order to remove the slag from the metal before casting 0.1-0.2% $ZnCl_2$ by weight of the charge is added. Addn. of Ti changes the macrostructure and facilitates working under pressure while Mg improves the strength. The optimum addn. of Mg is 0.3-0.5%. Best temp. for forging is 530-570° and for pressing it is 400-450°. B. Z. Kamich

Rolling magnesium-aluminum alloy sheets. S. M. Voronov and L. Ya. Shpolyanskiĭ. *Aviapromyshlennost* **1939**, No. 3, 11-22. Expts. are described on the rolling of Mg-Al sheets of the Altmag type (5-10% Mg, 0.4-0.8%, 0.1-0.2% Ti, rest Al). Alloys contg. 5-6% Mg were not satisfactorily hot-rolled in the cast state and must be deformed preliminarily. Subsequent hot-rolling proceeds without difficulty as does cold-rolling. The alloy was heat-treated at 425-450° and followed by quenching in water or in moving air. Alloys contg. up to 9% Mg showed in the hardened condition a tensile strength of 35-36 kg./sq. mm. and a relative elongation of 20-25%. The mech. properties of the alloys can be improved by slight hardening. In the semihardened state the alloy contg. up to 9% Mg had a tensile strength of 42-44 kg./sq. mm. and a relative elongation of 10-12%. Both the hardened and semihardened alloys are easily cold-stamped. B. Z. Kamich

Alloys of magnesium and intermetallic compounds. K. V. Peredel'skiĭ. *Aviapromyshlennost* **1939**, No. 3, 40-1.—Mech. and casting properties of alloys of Mg with intermetallic compds. of Sb_2Ni_5, Cu_4Sn, Cu_3Sb and $MgZn_5$ in amts. up to 10% were investigated. Alloys contg. 3% $MgZn_5$ gave the highest tensile strength of 18.9 kg./sq. mm. and an elongation of 10.7% which were higher than for all the other compds. B. Z. Kamich

Magnesium alloys containing intermetallic compounds. K. V. Peredel'skiĭ. *Vestnik Inzhenerov i Tekh.* **1939**, No. 8, 356-8.—The casting and mech. properties of Mg alloys contg. intermetallic compds. CuMg, Al_6Mg_4Cu, Cu_2Mg and SbSn in amts. up to 20.0% were studied. The alloys were prepd. in an elec. furnace under a flux of F and Cl salts. The alloys were satisfactorily cast in metal and earth forms. Addn. of CuMg raises the tensile strength and it reaches a max. of 17.2 kg./sq. mm. for 5.0% CuMg and also a max. Brinell hardness of 50 after which they begin to drop. The elongation remains practically const. at about 8% up to 3% CuMg and then falls off. For 3% Al_6Mg_4Cu the max. tensile strength was 17.8 kg./sq. mm. The hardness rises continually while the elongation reaches a max. of 9.5% for 3% Al_6Mg_4Cu and then falls off. Addn. of Cu_2Mg up to 10% gives a max. tensile strength of 19.0 kg./sq. mm. The elongation decreases while the hardness increases with the addn. of Cu_2Mg. SbSn raises sharply the tensile strength and it reaches a max. of 21.5 kg./sq. mm. for 0.5% SbSn but any further increase in SbSn lowers the tensile strength and it becomes const. for 15% SbSn. For 0.5-1.0% SbSn the elongation rises to 10-11% and then falls off. The hardness reached max. values at 0.5% and 15.0% SbSn. B. Z. Kamich

Effect of the quenching medium upon the mechanical properties of magnesium alloys. I. G. Shul'gin. *Aviapromyshlennost* **1939**, No. 7-8, 60-3.—Mg alloys contg. about 3.4% Al, 4.0% Zn, 0.13% Mn, 0.1% Fe and traces of Si were quenched at 420° (held for 6 hrs.) in cold water, hot water (100°), oil (20°), and in air and also quenched and tempered at 175° (held for 6, 12 and 24 hrs.) in the same media. The results show that quenching in all these media gives about the same mech. properties. The most thorough quenching with subsequent tempering was obtained by cooling the material in water and the least thorough by cooling in air. Quenching in water at 100°, especially after extended tempering at 175°, is close to quenching in water while quenching in air is next in effect. B. Z. Kamich

A note on yttrium-aluminum alloys. W. Kroll. *Metals & Alloys* **10**, 332-3(1939).—The effect of Y and other rare earths on the high-temp. strength or hot-hardness of Al piston alloys was studied. While Y addns. somewhat increased the hardness of certain alloys and maintained a slightly higher level of hardness over the temp. range to 300°, the effect is not impressive, especially in view of the present high cost of Y. 9 references. I. Hartmann

Refinement of grain of worked aluminum bronze. Hideo Nishimura. *Nippon Kinzoku Gakkai-Si* **3**, 321-4(1939).—Effects of Cr, Co, Fe or Ti were examd. upon the grain size of worked Al bronzes contg. 6 or 8% of Al. The specimens were cold-rolled to about 60% reduction and annealed at 700° or 800°. The grain sizes of the recrystd. metals were measured. Conclusion: The grain-refinement was effective by addns. of element in the order of Cr, Ti, Co, and Fe as the contents increase. H. N

Copper-zirconium-cadmium bronze. F. R. Hensel, E. I. Larsen and A. S. Doty. *Metals & Alloys* **10**, 372-80(1939).—An investigation of the melting procedures of the alloy, the effect of various deoxidizers on the age-hardening characteristics, the effect of combining cold working and aging, phys. properties, the effect of quenching temp. on the microstructure, the effect of Zr on alloys other than Cd, etc. The investigation produced a new (Cu-Zr-Cd) high-strength, high-cond. alloy; it constitutes a very substantial improvement in hardness and strength over the present Cu-Cd bronzes. The alloy is being used for elec. conducting members, welding electrodes and heat-conducting members. 3 references. I. Hartmann

Substitutes for tin bronzes in airplane engines. V. S. Rzheznikov and B. L. Slinko. *Aviapromyshlennost* **1939**, No. 7-8, 43-60.—On the basis of numerous tests recommendations are made for the use of substitutes for Sn bronzes in airplane engines. For conditions of high impact loads and small speeds of slipping Al bronzes are suitable,

especially the bronze contg. Al 8–10, Fe 3–4% and the rest Cu. For high speeds of slipping and for medium and high loads (up to 60–80 kg./sq. cm.) the bronze contg. Sn 4–6, Pb 23–26%, and the rest Cu is suggested. For especially high speeds of slipping the bronze contg. 9.5–11.5% Al, 3.5–4.5% Fe, 3.5–4.5% Ni, and the rest Cu is suggested. B. Z. Kamich

Plating Duralumin alloy 24S with aluminum-magnesium alloys. V. N. Rzhevtsev. *Aviapromyshlennost* **1939**, No. 3, 26–34.— Duralumin 24S (4% Cu, 1.5% Mg, 0.5% Mn) was plated with Al-Mg alloys contg. 2–9% Mg. By increasing the Mg to 4–5% in the plating layer the tensile stiength and the yield point are increased approx. by 1–1.5 kg./sq. mm. and the plastic properties of the metal are thereby changed very little. The plated alloys were tested against corrosion in a soln. of 3% NaCl and 0.1% H_2O_2. By maintaining a homogeneous structure the plating contg. 4% Mg was just as resistant to corrosion as pure Al while that with 5% Mg was only slightly less resistant. The presence of Mg in the plating layer impedes the diffusion of Cu. For alloys with different amts. of Mg in the plated layer the same heat-treatment produced more dispersed Cu particles and a less deep penetration into the plated layer in accordance as the Mg in the latter increased. B. Z. Kamich

Protection of magnesium alloys against corrosion. A. T. Bundin. *Aviapromyshlennost* **1939**, No. 9, 49–59.— At the present time the aviation industry in the Soviet Union uses the following methods of protecting mechanically treated Mg alloy objects against corrosion: (1) degreasing with org. solvent, degreasing with phosphate soln., washing in cold water, washing in hot water, oxidation, washing in cold water, drying and painting, and (2) degreasing with org. compds., treatment with a 20% CrO_3 soln., washing in hot water and drying. The effects on Mg of the compn. of the oxidizing bath, concn., duration of oxidation and contact with other metals were studied. One-min. treatment in 20% CrO_3 gave the best protective film 0.02–5 0.035 mm thick. In joining Mg parts to Mg or to brass, steel and Duralumin the Mg should be oxidized with H_2SO_4. B. Z. Kamich

Preventing corrosion of oil-well compressor tubes. B. Sheinin. *Novosti Tekhniki* **1939**, No. 22, 29–30.— Corrosion of compressor tubes in oil wells which are kept flowing with the aid of air-gas lift was reduced by coating the end tubes with 3 layers of Bakelite to which kaolin and a plastifier were added. After the application of each coating the tube is dried for 2 hrs. and then subjected to the following heat-treatment: 2 hrs. at 80° and 90°, 1 hr. at 100° and 110°, and 2 hrs. at 120°, 140°, and 160°. Tests with tubes treated in this manner were satisfactory. B. Z. Kamich

Dropping tests for measuring the thickness of zinc and cadmium coatings on steel. Abner Brenner. *J. Research Natl. Bur. Standards* **23**, 387–407 (1939) (Research Paper No. 1240).—A corrosive soln. drops onto a Zn or Cd coating. The penetration time is proportional to the thickness. B. finds a soln. contg. 200 g./l. CrO_3 + 50 g./l. H_2SO_4 is preferable to Hull and Strausser's (cf. *C. A.* **30**, 8037) acidified NH_4NO_3 solns., especially for Zn + Hg coatings, and for Cd on cast Fe. A stripping soln. contg. 20 g. $SbCl_3$ per l. coned. HCl is often preferable as an umpire test to the microscopic method. F. W. F.

Corrosion of metals as an electrochemical problem. A. Til. *Sbornik Elektrokhim. Teoriya Korrozii* **1938**, 30–52; *Khim. Referat. Zhur.* **2**, No. 1, 130–1 (1939).—Theoretics of the mechanism of corrosion are reviewed. The theory of local elements is of most importance. That absolutely pure metals do not corrode was verified on a sample of specially purified Zn. A slight corrosion of Zn in 0.5 *N* HCl took place only at breaking points, or scratches. Corrosion of ordinary Zn was different in different samples, and it even changed on polishing over the same sample. In all cases (after an initial period) the soln. velocity was const. When Zn was connected to an electrode of a different metal contained in the same soln. the corrosion velocity increased while the amt. of H (evolved on Zn decreased (difference effect). The value of the difference effect was proportional to the current flowing in the element. This is explained by the increase of the concn. of Zn in the contact layer of the soln., which was caused by increased soln. of Zn, and which was connected with the change of the potential of Zn. In strong currents passivity of the electrode is possible. The increasing action depends on the nature of the metal of the auxiliary electrode (increases with a decrease of the overvoltage of H). For Al (sol. in alkali) the difference effect is larger than for Zn. When dissolved in HCl the difference effect of Al is opposite in sign (the reason remains undetd.). The accelerating action of graphite on the soln. of Zn cannot be explained by low overvoltage of H on graphite, since this is of the same order of magnitude as that of Pb. W. R. Henn

Corrosion of heat-resistant steels in high-sulfur furnace gases. F. F. Khimushin, G. I. Zharov and P. D. Arlievskiĭ. *Kachestvennaya Stal* **6**, No. 3, 14–23 (1938).—The corrosion of Cr-Ni, Cr, Cr-Mn heat-resistant steels was tested in furnace gases contg. 0.5–3% SO_2 at high temps. up to 1100°. The tests lasted up to 200 hrs. Most of the Cr-Mn steels had an insufficient corrosion resistance and high brittleness at temps. of 500–900° and prolonged heating periods. Sulfide corrosion of Cr-Ni steels does not as a rule spread over the whole area, especially when the temp. is 900° but it penetrates into the metal. Cr-Ni steels showed no sulfide corrosion at temps. below 900° and after tests of 300 hrs. B. Z. Kamich

Corrosion of valves in pumps used for deep-well pumping. B. Sheinin. *Novosti Tekhniki* **1939**, No. 17–18, 37.—The corrosion of valves in pumps used for deep-well pumping was considerably reduced by employing a stainless steel valve seat and Cr-plated valve balls. The Cr plating is carried out in the following bath: CrO_3 250 g./l. and H_2SO_4 2.5 g./l. Duration of plating is 1 hr. at a. c. d. of 20 amps./sq. dm. and 63°; this gives a Cr layer of 0.01 mm. To decrease the brittleness the balls are kept in oil at 200° for 2–3 hrs. B. Z. Kamich

Protective greases for airplane engines. V. A. Yakhlakov. *Aviapromyshlennost* **1939**, No. 7–8, 9–24.—The corrosion of inside surfaces of airplane engines and the characteristics of various protective greases are discussed. Results are reported on tests conducted with the following 2 greases for protecting inside and outside airplane engine surfaces, resp.: (1) butanol 10, Al stearate 10, triethanolamine 6.5 and lard 73.5% and (2) oil 98, triethanolamine oleate 1.5 and triethanolamine 0.5%. The tests were conducted with various metals and on the basis of these tests it is claimed that these greases are equal to those of the Ethyl Gasoline Corp. B. Z. Kamich

Fabricated stainless steel (Vollrath) **25**. Use of city and natural gas for metal cutting (Wierum) **21**. Cement from Kerch Iron and Steel Works blast-furnace slags (Tevfikov) **20**. Introduction of semiacid refractories in reheating furnaces of the Stalin New Kramatorsk Machine Works (Popov) **19**. Lubricating composition for metal-working operations (U. S. pat. 2,174,907) **22**. Elec. device for burning in furnace linings of metal furnaces (U. S. pat. 2,174,927) **4**.

Ore concentration by froth flotation. Anderson W. Ralston and Wm. O. Pool (to Armour and Co.). U. S. 2,175,093, Oct. 3. Flotation agents are used comprising sebaconitrile or other aliphatic dinitrile of the general formula $NC(CH_2)_xCN$ in which x is at least 4.

Ore treatments such as in froth flotation or cyaniding. Harry V. Wallace and Leland H. Logue (to Mining Process and Patent Co.). U. S. 2,174,540, Oct. 3. Various details of app. and operation.

Apparatus for preferential grinding and scrubbing of ores and minerals with air treatment. Holbert E. Dunn (to Vanadium Corp. of America). U. S. 2,175,457, Oct. 10. Various structural and operative details.

Dry concentration of carnotite ores. Charles P. Rees, Holbert E. Dunn and Archibald A. Sproul (to Vanadium Corp. of America). U. S. 2,175,484, Oct. 10. A process of concg. the V and U content of carnotite ores comprises crushing the ore to a size only slightly coarser than its single

grain size, subjecting the crushed ore to air classification to an extent sufficient to provide a free-flowing feed adapted to electromagnetic sepn., subjecting the ore to electromagnetic sepn., subjecting the nonresponsive discard from the electromagnetic sepn. to pneumatic scrubbing to remove encrusting V and U minerals, and sepg. the valuable fines from the coarse tailings by air classification.

Recovery of metals such as gold, silver or copper from solutions. Albert B. Doran. U. S. 2,174,570, Oct. 3. For the recovery of a metal from soln., the soln. is treated with an insol. permanganite salt of a metal more electropositive than the desired metal, the amt. of the permanganite being at least slightly in excess of that chem. equiv. to the metal which it is desired to recover, whereby an insol. permanganite salt of the desired metal and a spent soln. substantially exhausted in the metal are formed.

Hydraulic apparatus for saving fine gold. Geo. B. McKeever. U. S. 2,174,925, Oct. 3. Various structural, mech. and operative details.

Tilting crucible furnace suitable for melting and refining metals. Isaiah Hall. U. S. 2,175,462, Oct. 10. Various structural, mech. and operative details.

Roller-hearth conveyer-type furnace suitable for heat-treatment of metal sheets, etc. Edward S. Fatkin (to Westinghouse Elec. & Mfg. Co.). U. S. 2,175,834, Oct. 10. Various structural, mech. and operative details.

Roller-hearth furnace for heat-treating copper tubes, steel strips, etc. Arthur H. Vaughan (to Elec. Furnace Co.). U. S. 2,175,233, Oct. 10 Various structural and mech. details.

Vaporizing furnace for metals such as zinc. Geo. Anderson and Rangwald S. Olsen (to International Smelting & Refining Co.). U. S. 2,174,559, Oct. 3. A metal-supporting floor for a vaporizing chamber comprises a series of trays each independently supported in the chamber so as to carry only its own load of molten Zn.

Utilizing fuel oils in the operation of iron blast furnaces. Marvin W. Ditto (to Emulsions Process Corp.). U. S. 2,175,517, Oct. 10. App. is described, and a process for the production of pig iron in a blast furnace which involves introducing a water-in-fuel oil emulsion into the tuyère zone of the furnace, the oil in the emulsion being sufficient upon combustion to generate at least the amount of heat required to decompose the water vapor derived from the water to form CO and H in the presence of the C produced by the hydrocarbons of the fuel oil, whereby a gas of high calorific value and relatively low in total N is produced.

Ladle for use in casting copper wire-bars. Adolphe Busche and John H. Jago (to American Smelting and Refining Co.). U. S. 2,175,375, Oct. 10. Various structural details of a ladle adapted for preventing formation of substantial amts. of Cu oxide during pouring of the metal.

Blowpipe nozzle for cutting metals. Theodor Zobel and Ulrich Noetzlin (to Linde Air Products Co.). U. S. 2,175,160, Oct. 3. Various structural details.

Apparatus for heat-treatment of metals, as in annealing or normalizing. Howard Scott (to Westinghouse Elec. & Mfg. Co.). U. S. 2,175,922, Oct. 10. Various structural and operative details.

Fusible salt bath for case-hardening steels. Ernest A. Walen (to Heatbath Corp.). U. S. 2,175,417, Oct. 10. A mixt. suitable for carburizing steels of relatively low C content contains NaCN 40, $SrCl_2$ 20, Na_2CO_3 10, NaCl 20.45, KCl 5 and NaF 4.55%.

Apparatus for annealing steel wire or strip, etc. Carl J. Toll (to American Steel and Wire Co. of N. J.). U. S. 2,174,642, Oct. 3. Various structural and operative details.

Cast iron. Max Kuniansky. U. S. 2,174,519, Oct. 3. An arrangement of app. is described, and a method of making cast iron involving melting a mixt. of cast iron and malleable cast iron in a cupola furnace where C is picked up by the molten mass, casting this melt into ingots, remelting the ingots in a second cupola where addnl. C is picked up by the molten mass, and adding a graphitizing agent. Use of various alloys is described. U. S. 2,174,520 describes an arrangement of app., and a method of making cast iron contg. over 3% of C, which involves subjecting scrap predominantly of steel to a melting operation in a cupola furnace in contact with C, to add C to the molten material, casting this melt into ingots, and remelting the ingots in contact with C, to add further C up to a total above 3%.

Cyanide neutralizing pickled iron and steel sheets. Russell R. Smith, Hillard E. Miller and Ralph H. Gelder (to American Rolling Mill Co.). U. S. 2,175,620, Oct. 10. In a process of cyanide neutralizing pickled iron and steel sheets to be subsequently coated with Zn, Ni, Cd or enamel, etc., the cyanide soln. is maintained at a temp. of 60–82°, at a concn. of 0.12–0.15 oz. per gal. and with a treatment time of 4–40 sec.

Steel. Marvin W. Ditto (to Emulsions Process Corp.). U. S. 2,175,181, Oct. 10. App. including an open-hearth furnace is described, and a process which involves introducing lime and ferric scrap metal into the furnace, melting the scrap metal and then introducing cold iron, melting the cold iron, then injecting a water-in-oil emulsion into the pool of metal for a time sufficient, in conjunction with the lime boil, to oxidize the C, and maintaining the pool in molten condition during the injection of the emulsion by burning fuel in proximity to the point at which the emulsion is brought in contact with the pool. U. S. 2,175,182 describes app. and a process for the production of steel in an open-hearth furnace which involves impinging a jet of water-in-fuel oil emulsion traveling at high velocity and in atomized condition on the upper surface of a molten iron charge covered with slag, in an area constituting a portion only of the entire area of the surface, and thereby causing material turbulence at the upper portion of the charge and in the slag, simultaneously impinging a jet of water-in-fuel oil emulsion at high velocity and in atomized condition onto the upper surface of the charge in the first-mentioned area, from a point arranged laterally beyond the upper surface of the molten charge and thereby causing further turbulence at the upper portion of the charge and in the slag, and preventing undue chilling of the charge during such injection by burning fuel in proximity to the place of impingement.

Steel powder. Raymond L. Patterson and Claus G. Goetzel (to Hardy Metallurgical Co.). U. S. 2,175,850, Oct. 10. A process for making steel powder involves subjecting finely divided Fe oxide to the action of a reducing agent such as H under pressure at an elevated temp. to produce hot Fe powder, subjecting the Fe powder particles while maintaining them at an elevated temp. to the action of a carburizing agent such as a hydrocarbon gas until combined C has formed to a substantial depth below the surface of the particles, and partially decarburizing the resulting steel-powder particles while maintaining them at an elevated temp. by the action of a decarburizing agent such as H until a substantial proportion of C-free Fe has been restored in the portions of the particles adjacent their surface. The resulting product is suitable for molding under pressure with heat-treatment or for alloying.

Case-hardening steel. Arthur E. Bellis. U. S. 2,174,867, Oct. 3. A steel article is case hardened by dipping it in a fused salt bath contg. a eutectic mixt. of KCl and $MgCl_2$ together with about 0.5–3% of a mixt. of B nitride and Mg carbide (the bath being maintained in fused condition and at heat-treating temp. by passing an a. c. through it).

Controlling the strain sensitivity of steel. Herbert W. Graham and Samuel L. Case (to Jones & Laughlin Steel Corp.). U. S. 2,174,740, Oct. 3. Molten steel of desired compn. has nitrides of Fe and Al incorporated in it (suitably in proportions of about 1.5–3 lb. Al per ton) to give the metal product a desired strain sensitivity.

Alloy steels suitable for tools and dies. James P. Gill (to Vanadium-Alloys Steel Co.). U. S. 2,174,281, Sept. 26. A forgeable, machinable and hardenable alloy steel contains Fe together with C about 1.25–3.5, Mo about 3.5–10, Cr about 0.25–5 and V about 3–11%, the ratio of the V to the C being in excess of about 2:1 and less than about 4:1. U. S. 2,174,282 relates to alloys of generally similar compn. except that they do not contain Cr or Mo.

2,174,283 relates to generally like hardenable alloys . Mo but not Cr. U. S. 2,174,284 relates to forge- and machinable alloy steels contg. Fe together with C t 1.25–3.5, W 1–12 and V 3–10%, the ratio of the V being in excess of about 2:1 but less than about 4:1. 2,174,285 relates to otherwise generally similar alloys s. also Cr about 5.5% or less. U. S. 2,174,286 re- to tools or dies of such alloy steels contg. Fe together C 1.25–3.5, W 1–12, Mo 1–10, Cr 0.25–5 and V 3–

ist alloy steel engine parts such as valve seat rings and ider sleeve linings. George Charlton (to Eaton Mfg. . U. S. 2,175,683, Oct. 10. An alloy is used which m. it 1100–1300° and which contains Fe together with C -2.0, Cr 5–15, Si 0.25–2.0, Ni 20–40, B 0.25–3.0, P 5–2.0 and S 0.005–2.0%. Such alloys have good wear stance at high temps.

endering stainless steels resistant to acids. Henry Giles (to American Sheet and Tin Plate Co.). U. S. 75,771, Oct. 10. A method of immunizing stainless el against the corrosive attack of acids such as washing ior of nitrocellulose manuf. involves heating it to above crit. temp. to change the grain growth of the steel, the ip. and time of the heat-treatment being such as to ovide the outer surfaces of the steel with an unstrained l unstriated substantially rounded grain structure which isible under microscopic examination, cooling the heat- ated steel to about room temp. without changing such in structure and to a temp. which will permit the re- oval of oxide scale, and the metal is then exposed with surfaces cleaned to an oxidizing medium while the steel heated to a temp. which is materially above normal atm. np. but below its lower crit. point to provide the surface th an invisible corrosion-resistant oxide film.

Use of stainless steels in contact with chlorine. Hans . Kauffmann and Robert L. McEwen (to Buffalo Elec- o-Chemical Co.). U. S. 2,174,516, Oct. 3. A stainless eel is rendered resistant to active Cl by preliminary eatment with a persulfate such as that of K (suitably in l. aq. soln. at room temp. or a higher temp. for 6–48 rs.).

Facing steel with corrosion-resisting metal. Thomas B. hace (to Clad Metals Industries, Inc.). U. S. 2,174,733, ct. 3. A method of facing a steel backing with a corro- ion-resisting metal substantially free of Fe comprises onding to the face of the steel backing a thin intermediate ayer of a Ni-Cu alloy of such thickness as substantially o prevent migration of Fe into the corrosion-resisting metal from the steel backing when the corrosion-resisting metal is bonded to the intermediate layer and then bonding o the face of the layer of Ni-Cu alloy a facing of Cu-Si lloy. Cf. *C. A.* **33**, 5801[6].

Alloying the surface of metal bodies such as steel slabs with other metals such as chromium. Robert E. Kinkead. U. S. 2,175,606–7, Oct. 10. Various details of app and operation.

Alloys having artificial radioactivity. Oleg Yadoff. U. S. 2,175,236, Oct. 10. A method of prepg. an alloy having artificial radioactivity involves placing on the bottom of a furnace, in the cold state, Hg 0.5–1, adding Sn 4–6.5 and Pb 2.4–5, adding Cu 5–12 and Al 68–74%, melting these metals, introducing Mn 1.89–2% into the molten bath, heating to melt the materials together, evapg. Hg, adding Mg 4.2–8.4%, stirring, and subjecting the molten mixt. to an elec. field of high intensity corresponding to a tension of at least 100 v. per cm. of thickness of the molten alloy thus formed.

Treating aluminum alloys to effect better resistance to corrosion. Harry H. Wetzel (to Douglas Aircraft Co.). U. S. 2,174,645, Oct. 3. App. is described, and a method of treating a strong Al alloy such as "17S" alloy involving subjecting the alloy to a soln. heat-treatment, and cooling the alloy by introducing it at substantially the temp. of the soln. heat-treatment into a quenching atm. of fog-like character formed by atomizing a liquid such as water in a gas such as air.

Heat-resisting alloys suitable for resistance wires. Wm. M. Kay. U. S. 2,174,919, Oct. 3. Ni is alloyed with Cr 10–30, Th 0.01–2, Si 0.25–3 and Ce 0.01–2%. Ca, Mg and Zr also may be used.

Removing magnesium from aluminum alloys. Georg Messner (to I. G. Farbenind. A.-G.). U. S. 2,174,926, Oct. 3. Al alloys contg. Mg are treated with Cl at temps. above the m. p. of $MgCl_2$ but not substantially above 1000°, and the $MgCl_2$ formed is sepd. from the metal.

Treating iron-aluminum alloys. Franz Noll and Paul Wolf (to "Fides" Ges. fur die Verwaltung und Verwertung von gewerblichen Schutzrechten m. b. H.). U. S. 2,174,368, Sept. 26. A method of treating Fe-Al alloys contg. from about 1.5% up to 8% of Al to impart thereto a high initial permeability and improve the constancy thereof when subjected to weak magnetizing forces involves subjecting the alloy to cold work in an amt. ranging from 25 to 85%, annealing the cold-worked alloy at a temp. between 900° and 1100° in the presence of O, and slowly cooling the annealed alloy.

Copper-boron-silicon alloys. Horace F. Silliman (to American Brass Co.). U. S. 2,175,223, Oct. 10. Alloys which are of fine grain and resistant to corrosion contain Cu together with Si 0.1–5.0 and B 0.005–4.5%.

Lead-bismuth-lithium cable sheath alloy. Hans Osborg (to Maywood Chemical Works). U. S. 2,175,279, Oct. 10. An extrudable and workable Pb alloy contg. Bi and Li is prepd. by establishing a melt of Pb contg. about 0.03–0.09% of Bi, maintaining the melt at a temp. of at least about 425°, adding about 0.005–0.025% of Li and stirring to effect practically complete incorporation of any wet dross, and then casting. Cf. *C. A.* **33**, 2478[1].

Galvanizing articles such as sheets of steel. Thomas C. Scott (to Continental Steel Corp.). U. S. 2,175,706, Oct. 10. Articles to be galvanized are passed through a molten bath comprising a relatively deep supporting layer of Pb and a relatively thin layer of Zn, and immediately on emergence of the article from the bath the Zn coating on it, while still hot, is subjected to the action of a fluxing agent such as NH_4Cl in the presence of oxalic acid, in order to reduce Pb oxide formation.

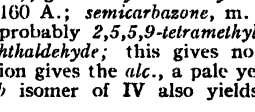
Apparatus for rust-proofing galvanized sheets by treatment with phosphoric acid, etc. Benjamin P. Finkbone, Geo. R. Hoover and Harvey F. Miller (to American Rolling Mill Co.). U. S. 2,175,599, Oct. 10. Various structural, mech. and operative details.

Welding electrodes and contacts. James M. Kelly (to Westinghouse Elec. & Mfg. Co.). U. S. 2,175,899, Oct. 10. A major proportion of a refractory metal powder such as W, Mo or Ta is mixed with a minor proportion of a highly conductive metal powder such as Cu or Ag and the mixt. is placed in a mold of refractory material such as graphite and over this mixt. there is placed a layer of a mixt. of a major proportion of a highly conductive metal powder and a minor proportion of a refractory metal powder and the materials are heated in the mold under pressure to produce a dense composite electrode having a contact tip of refractory metal and a shank of highly conductive metal (the heating being in a protective atm. such as H or N at a temp. above the m. p. of the highly conductive metal so that it serves as a bonding agent).

Flux compositions for use in soldering, welding, etc. Lionel Cinamon and Samuel Sklarew (to Special Chemicals Corp.). U. S. 2,174,551, Oct. 3. A high proportion of boric acid is used with other ingredients such as KHF_2, KBF_4 or K_2SiF_6.

10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST



Properties of long-chain compounds as functions of chain length. Maurice L. Huggins. *J. Phys. Chem.* **43**, 1083–98(1939).—From theoretical considerations, largely qual. in nature, certain conclusions have been reached regarding the variation with chain length of heat content, entropy, heat of fusion, heat of vaporization and vapor pressure of long-chain compds. at const. temp. Variation of b. p. with chain length has also been briefly discussed. Conclusions were tested, where possible, with expt. data for *n*-paraffin hydrocarbons. Oden E. Sheppard

Stability of polymorphous forms of long-chain hydrocarbons and their derivatives. Theodor Schoon. *Ber.* **72B**, 1821–7(1939).—S.'s system for deriving the possible cryst. forms of substances built up of long chains from a basic rhombic form by simple translation of the chain axis (*C. A.* **32**, 6523[9]) is briefly reviewed. Hitherto it was an entirely open question which of these possible forms are thermodynamically stable. Müller (*C. A.* **23**, 30), from considerations of symmetry, believed that paraffins with an even no. of C atoms have a monoclinic structure. Kohlhaas and Soremba (*C. A.* **33**, 2388[1]) raised the question whether in the case of $C_{30}H_{62}$ the rhombic α-form might not be the more stable modification and hence not obey the Muller rule. To clear up this point the relative stabilities of the 2 forms (α and γ_1) were studied by means of Müller spectrograms of their intraconversion. Their transformation temps. and m. ps., resp., were found to be: α, 60°, 67°; γ_1, 60°, 66°. Their spectrograms at 20°, 61° and after cooling to 20°, which are reproduced, show that the rhombic α-form is in fact the more stable modification. Whether the γ_1-form is totally unstable or becomes stable at much lower temps. cannot be detd. experimentally. From simple considerations it is concluded that the monoclinic high-temp. ϵ_2-form of stearic acid is very probably totally stable, as in this cryst. form the structural units must be in a state of abs. min. of free energy. C. A. R.

Oxidation to aliphatic acids of olefins prepared from paraffin. Henning Scheller. *Ber.* **72B**, 1917–26(1939). Air oxidation of paraffins to aliphatic acids has the disadvantage of giving no homogeneous product, with or without a catalyst, under normal or increased pressure, at high or low temps. The object of the present work was to obtain light on the course of the reaction by a method in which the oxidation of the paraffin proceeded under the simplest possible conditions. For this purpose it was desirable to produce in the chain of a normal paraffin a sensitive position which offered a preferential point of attack. It was sought to attain this object by chlorinating paraffin, converting it into an olefin by elimination of HCl, and subjecting it to oxidation either (1) at the double bond (with O_3, $KMnO_4$, HOCl, etc.) or (2) at the C atom adjacent to the double bond while preserving the double bond (with O, SeO_2, CrO_3, etc.). For the prepn. of relatively large amts. of olefins recourse was had, in part, to the process of Schaarschmidt and Thiele (*C. A.* **15**, 1309). A purified com. hard paraffin, m. 68–70°, av. mol. wt. 420 (Rast), chlorinated slightly above its m. p. until it had absorbed 0.5 mol. Cl, yielded a product of salve-like consistency, m. 58–62°, which at 300° rapidly and quantitatively split off the Cl as HCl. The resulting dark oil underwent extensive cracking when distd. under atm. pressure and was therefore distd. under 3 mm.; the olefin so obtained was white, with a faint yellowish shimmer, m. 47–50°, av. mol. wt. 410, I no. 58. Homogeneous triacontane, m. 66.8° (obtained by electrolysis of the Na salt of pure palmitic acid, m. 62°), was then chlorinated under the same conditions, because com. paraffin yields a large no. of products; heating the product under atm. pressure at 300° and then distg. it *in vacuo* gave a pure white cryst. olefin, m. 58–60°, I no. 50, showing no evidence of the presence of conjugated double bonds (neg. results in diene no. detns. with maleic anhydride). To obtain light on the positions of the double bonds the olefin was subjected to ozonolysis and subsequent oxidation of the aldehydes to the acids. It was ozonized in CCl_4 at 0° and the ozonide was cleaved by boiling with water in the presence of a little H_2O_2. The neutral portion (about 30%) remaining after sepg. the CO_2H acids had the very low I no. 6, showing that the product used for the ozonization had contained about 70% olefin and the ozonization had been practically quant. The neutral portion was a white solid, m. 64°, consisting mostly of unchanged triacontane. The light yellow acids, sepd. through the Na salts, were mainly satd. aliphatic acids (I no. 10). In the water used for boiling out, the only sol. acid present was formic; the next higher homologs (acetic, propionic, butyric, valeric) could not, at any rate, be detected, nor could oxalic acid. Hence the chlorination must have attacked principally the end α- or β-C atoms. Detns. of the HCO_2H showed 23% of the theoretically possible amt. of acid. As no AcOH was found it is probable that all of the Cl in the chlorinated product was on the α-Cl atom. The acids were converted into the Me esters and fractionated; below are given, resp., the b. ps. (pressures in parentheses), wts., phys. state, color, MeO content, mol. wt. calcd. for $C_nH_{2n+1}CO_2Me$ from the MeO content, and mol. wt. found in freezing benzene, for the various fractions: 90–150° (8 mm.), 1.70 g., liquid, colorless, 15.86%, 195, 188; 90–135° (0.08 mm.), 2.20 g., liquid, colorless, 13.86%, 236, 249; 135–70° (0.08 mm.), 2.20 g., solid, yellow, 10.55%, 291, 302; 150–70° (0.005 mm.), 2.40 g., solid, yellow, 9.09%, 311, 359; 170–80° (0.005 mm.), 2.20 g., solid, brown-yellow, 8.33%, 372, 383; 250–5° (0.005 mm.), 1.32 g., solid, brown, 6.95%, 446, 459; residue, 1.20 g., black solid. The good agreement between the calcd. and found mol. wts. indicates these fractions were indeed esters of aliphatic monocarboxylic acids with 10–29 C atoms. Oxidation of the olefin with air (about 5 l. per hr. per 70 g. olefin) for 48 hrs. at about 105° gave a light-yellow product of acid no. 80, I no. 63, yielding about 35% light-yellow acids of I no. 50. The yellow unsaponifiable part had an I no. of 82. Pure O under the same conditions gave in 24 hrs. a light-yellow product of acid no. 126, I no. 65, yielding about 50% of yellow acids with sapon. no. 182, I no. 54; I no. of unsaponifiable part, 90. In both cases the unsaponifiable part was no longer a pure olefin. Its av. mol. wt., 615, and its O content indicated it consisted of polymerization products and also contained oxidation products. The acids contained small amts. of HO acids insol. in petr. ether. The I nos. of the acids were about the same as that of the original olefin. The oxidation must therefore have occurred according to (2) above. After ozonization at 0° and boiling of the ozonide with water contg. a little HNO_3, the water contained, along with traces of HCO_2H, oxalic and succinic acids but no malonic acid. Hence the oxidation with air or O had occurred principally at the C atoms adjacent to the double bond. The Me esters of the acids obtained with air or O gave fractions with the following properties (b. p., wt., phys. state, color, MeO content, calcd. mol. wt., found mol. wt., I no., resp.): 95–135° (8 mm.), 0.90 g., liquid, colorless, 17.06%, 182, 175, 15; 90–140° (0.01 mm.), 1.90 g., liquid, colorless, 12.11%, 256, 262, 24; 140–70° (0.01 mm.), 1.30 g., solid, yellowish, 10.41%, 297, 300, 47; 170–95° (0.01 mm.), 1.90 g., solid, yellow, 8.39%, 370, 379, 63; 195–215° (0.01 mm.), 1.55 g., solid, brown-yellow, 7.76%, 400, 410, 74; 215–40° (0.01 mm.), 1.80 g., solid, brown, 6.89%, 450, 465, 86; residue, 0.65 g., brown-black solid. The acids therefore had about the same mol. wts. as those obtained with O_3 but were unsatd. and not pure carboxylic acids; analysis showed they contained more O than corresponded to that in the CO_2H group. The olefin obtained from the com. paraffin was subjected to similar oxidations, in part in the presence of 0.1% of various catalysts (Ba, Ca, Mn and Al stearates, cobaltous-cobaltic oxide, hopcalite). With air there were obtained more or less colored products with acid nos. 67–78. After 48 hrs. oxidation the I no. was in no case

higher than 62. In most cases the catalysts did not appreciably affect the results but with hopcalite the I nos. of the oxidation product, the aliphatic acid mixt. and the unsaponifiable portion were appreciably lower. The neutralization nos. and m. ps. of all the acid mixts. were approx. the same. The av. yield of acids was 30% and their I nos. (except of that obtained with hopcalite) not much lower than that of the starting material. Ozonization in CCl_4 and cleavage of the ozonides gave oxalic and succinic acids. The unsaponifiable portions had an av. mol. wt. of 585 and contained O. The aliphatic acids all had approx. the same consts., contained HO acids and yielded soaps which foamed well. The Me esters showed the following properties (given in the same order as above): 75–109° (0.05 mm.), 6.68 g., liquid, colorless, 17.23%, 180, 207, 19; 100 35° (0.05 mm.), 7.60 g., liquid, colorless, 10.49%, 296, 301, 53; 135–90° (0.05 mm.), 7.62 g., solid, yellow, 8.96%, 346, 360, 60; 190–230° (0.05 mm.), 5.89 g., solid, brown-yellow, 7.00%, 413, 446, 76; residue, 4.20 g., black solid. Pure O instead of air gave, in half as long a time, a light-yellow product with acid no. 126, and 40% of acids with the same consts. as those obtained with air. Hard paraffin treated with air under the same conditions (48 hrs. at 105°) was unchanged. C. A. R.

Polyene series. I. E. Barraclough, J. W. Batty, I. M. Heilbron and W. E. Jones. *J. Chem. Soc.* **1939**, 1549–54. It has been shown (*C. A.* **31**, 5369[3]) that citral (I) condenses with crotonaldehyde (II) with a neutral piperidine-AcOH catalyst to give 3 isomeric aldehydes. With an excess of AcOH, the results are very similar, although the reaction period is greatly reduced; the addn. of a small proportion of silica gel to either the neutral or the acid catalyst results in a considerable increase in the total yield of condensation products with a marked reduction in the quantity of undistillable resin. Citrylidenecrotonaldehyde *a* (III) (from the semicarbazone, m. 160°, $\lambda_{max.}$ 3255 A.) is reduced by (iso-$PrO)_3Al$ in iso-PrOH to *7,11-dimethyl-2,4,6,10-dodecatetraen-1-ol*, b_{30} 200–10°, pale-yellow oil, $\lambda_{max.}$ 2680 A. ($\epsilon_{max.}$ 42,000), which contains 4 double bonds. The *b* isomer (IV) of III (semicarbazone, m. 206°, $\lambda_{max.}$ 3255 A.) is acyclic and contains 4 double bonds. Condensation of I and II in dry Et_2O with $NaNH_2$ as catalyst gives III and a new *semicarbazone* (V), $C_{16}H_{23}ON_3$, m. 186°. I and AcH with $NaNH_2$ in Et_2O give citrylideneacetaldehyde (semicarbazone, m. 170°) and small quantity of V, III could not be detected. I and β-methylcrotonaldehyde with $NaNH_2$ in Et_2O give a mixt. of *ψ-ionylideneacetaldehyde a* (VI), $C_{18}H_{22}O$, and *b* (VII), whose *semicarbazones*, m. 178–9° and 112°, resp., are sepd. by crystn. from 80% MeOH. VI and VII are pale-yellow oils with $\lambda_{max.}$ at 3150 A. Reduction of IV, VI and VII gives the corresponding alcs. as readily autoxidizable oils with $\lambda_{max.}$ 2650, 2650 and 2660 A. The action of O_3 on III and VI gives 77 and 70% of the theory of Me_2CO but no AcH. PhCH:CHCHO and AcH with $AcNH_2$ give cinnamylideneacetaldehyde, $\lambda_{max.}$ 3390 A., $\epsilon_{max.}$ 52,460. III and Me_2CO give *2-keto-10,14-dimethyl-3,5,7,9,13-pentadecapentaene*, b_1 140–5°, λ_{max} 3580 A. (*semicarbazone*, m. 171°, λ_{max} 3500 A.). VI gives the *6,10,14-trimethyl* deriv., $b_{0.4}$ 161° (semicarbazone, m. 161°, $\lambda_{max.}$ 3500 A.). II. I. M. Heilbron, W. E. Jones and A. Spinks. *Ibid.* 1554–6. *ψ*-Ionone semicarbazone (20 g.) with 200 cc. H_3PO_4 at room temp. gives 14 g. of an ionone, almost exclusively the β-isomer. Citrylideneacetaldehyde semicarbazone gives a yellow oil, which is probably *β-cyclocitrylideneacetaldehyde* (I), λ_{max} 2930 A., $\epsilon_{max.}$ 8000, whose *semicarbazone*, pale yellow, m. 186–7°, $\lambda_{max.}$ 2950 A., $\epsilon_{max.}$ 27,400. O_3 and I give geronic acid. I condenses with Me_2CO to give the ketone $CMe:C(CH:CHCH:CHAc)\cdot CMe_2.CH_2.CH_2.CH_3$, $b_{0.17}$ 140–5° m. 186°, $\lambda_{max.}$ 3160 A., ϵ_{max} 38,000. III. J. W. Batty, I. M. Heilbron and W. F. Jones. *Ibid.* 1656–60.—Citrylidenecrotonaldehyde *a* (I) semicarbazone (m. 160°), added to 100 cc. H_3PO_4 (d. 1.75) with stirring at room temp. during 1 hr. and distn. with steam in the presence of 25 g. $C_6H_4(CO)_2O$ in N stream, gives 5.1 g. of *5,5,9-trimethyl-5,6,7,8,9,10-hexahydro-1-naphthaldehyde* (II), m. 60–1°, $\lambda_{max.}$ 3210 A.; *semicarbazone*, with 1 mole MeOH, m. 114°, from Et_2O-light petr., m. 169–71°; *2,4-dinitrophenylhydrazone*, red, m. 186°. Reduction of 3 g. II with (iso-$PrO)_3Al$ in iso-PrOH at 110–20° gives 2 g. of the *alc.*, $C_{14}H_{22}O$, pale yellow viscous oil; $SbCl_3$-$CHCl_3$ gives a blue-violet color; absorption bands 6410, 5800, 5030 A.; the H absorption corresponds to 3 double bonds but results in the formation of the hydrocarbon. With O_3 II gives a diketodicarboxylic acid, $C_{12}H_{18}O_3$ (*semicarbazone*, m. 163°); no Me_2CO was found. The semicarbazone of the *b* isomer of I gives an *aldehyde*, possibly III (R = H), m. 56.5–60°; *semicarbazone*, m. 221–2°; *2,4-dinitrophenylhydrazone*, red, m. 253–4°. Reduction gives the *alc.*, pale yellow, showing no selective absorption in the ultraviolet; further reduction gives a hydrocarbon. *ψ*-Ionylideneacetaldehyde *a* semicarbazone (IV), gives a *cyclic aldehyde* (V), pale yellow oil, $\lambda_{max.}$ 3160 A.; *semicarbazone*, m. 188–9°, $\lambda_{max.}$ 3250 A.; V is probably *2,5,5,9-tetramethyl-5,6,7,8,9,10-hexahydro-1-naphthaldehyde;* this gives no geronic acid with O_3; reduction gives the *alc.*, a pale yellow oil, λ_m 2720 A. The *b* isomer of IV also yields an *aldehyde*

(III, R = Me), a pale yellow oil (*semicarbazone*, m. 214–15°). The results indicate that I is derived from the trans form of citral (i. e., citral *a* or geranial), whereas the *b* isomer is related to the cis isomer (citral *b* or neral). IV. I. M. Heilbron, A. E. Johnson and W. E. Jones. *Ibid.* 1560–3.—Oxidation of vitamin A (I) with (iso-$PrO)_3Al$ in the presence of Me_2CO gives the same C_{23} ketone (axerophthylideneacetone (II)) as is obtained by using (*tert*-$BuO)_3Al$ (*C. A.* **32**, 3346[3]). Reduction of II by (iso-$PrO)_3Al$ in iso-PrOH gives a secondary alc. (III), viscous orange oil, λ_{max} 3545 A., $E^{1\%}_{1cm.}$ 1250; $SbCl_3$ in $CHCl_3$ gives an intense greenish blue color with a strong band at 7120 A. Oxidation of II or III with O_3 gives geronic acid, thus confirming the presence of the β-ionone ring; neg. results were obtained with the product formed by oxidation of I in Et_2CO or the corresponding alc. PhCH:$CHCH_2OH$ and (iso-$Pr)_2CO$ in C_6H_6 with (*tert*-$BuO)_3Al$ give 5% of PhCH:CHCHO; with Et_2CO there results *α-cinnamylidenediethyl ketone*, PhCH:CHCH:CMeCOEt, pale yellow, m. 63°, $\lambda_{max.}$ 3220 A., $\epsilon_{max.}$ 33,400 (*2,4-dinitrophenylhydrazone*, reddish violet, m. 232°). $PhCH_2OH$ and Et_2CO give *α*-benzylidenediethyl ketone and furfuryl alc. yields α-furfurylidenediethyl ketone, b_{21} 135–40°; *semicarbazone*, m. 181°, λ_{max} 3160 A., $\epsilon_{max.}$ 74,000; *2,4-dinitrophenylhydrazone*, reddish violet, m. 188°. Geraniol gives mainly high-boiling products. C. J. West

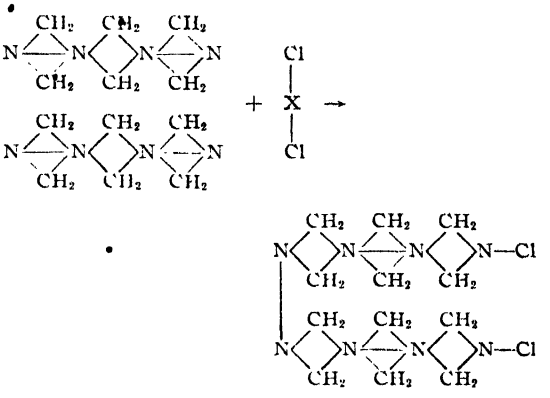
Chlorine derivatives of the aliphatic series. XV. Chlorination of isobutylene. I. D'yakonov and D. Tishchenko. *J. Gen. Chem.* (U. S. S. R.) **9**, 1258–64 (1939); cf. *C. A.* **33**, 4190[1,6].—Isobutylene with approx. an equal vol. of Cl gave, after fractional distn., 90 g. Me_2CCl (I), b. 52 4°, 88 g. isobutenyl chloride (II), b. 71–4°, 61 g. 1,2-dichloroisobutane, b. 107–10°, 231 g. of a mixt. contg. approx. 40% (dctd. by hydrolysis) 1-chloro-2-chloromethyl-2-propene (III) and 60% 1,3-dichloro-2-methyl-1-propene (IV), b. 131–4°, and a mixt. of trichloroisobutanes, not investigated further. I was identified by hydrolysis to Me_2COH, m. 25°, b. 80–2°. III and IV were identified by oxidation of the mixt. of III and IV with O_3 to give $ClCH_2COMe$ (semicarbazone, m. 142–3°), and $(ClCH_2)_2CO$. The chlorination of II at 0° in the presence of $NaHCO_3$ also gave a mixt. of III and IV, in addn. to other products. Based on the exptl. data the chlorination of isobutylene is an anomalous reaction, similar to that previously observed for other ethylene hydrocarbons with a tertiary C atom at the double bond.

John Livak

The relations of "oxygen and peroxide effect," and of hypochlorous acid addition, to the structures of unsatu-

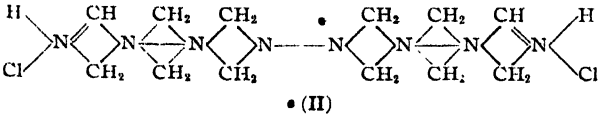
rated organic compounds. Arthur Michael. *J. Org. Chem.* 4, 519–30(1939).—Based on the results of his own expts. and those of Kharasch and coworkers (30 references) on the addn. of hydrogen halides and hypohalous acids to unsatd. compds. and on the relationship of "O and peroxide effect" upon these reactions, M. gives some theoretical interpretations to explain the structures of the halohydrins formed from aliphatic α,β-unsatd. compds. and the quant. relations between them. He explains the accelerated velocity of these addns. over those of the H halides and formulates the direct connection between the abnormal addns. and the chem. structure of the unsatd. compds. These interpretations also explain how mol. O and peroxides act catalytically in abnormal HBr addns.: they connect changes in the mode of addn. with relative reaction facility. Further exptl. development of the phenomena is suggested. In the Winstein and Lucas interpretation (*C. A.* **32**, 4861[1]) there is no connection between the adherence of normal addn. and the magnitude of the oxidant effect or with the structures of the unsatd. org. compds. It is based upon a series of speculations, which are wholly without exptl. support and which are opposed not only to the fundamental law on addn. in org. reactions, but to the affinity relations between C and O.
F. E. Brauns

Solvent and peroxide effect in the addition of hydrogen bromide to trimethylethylene. Arthur Michael and Nathan Weiner. *J. Org. Chem.* **4**, 531–42(1939).—According to Kharasch (*C. A.* **27**, 3444) abnormal addn. through peroxide influence occurs only in alkenes with terminal unsatn. Trimethylethylene (I), b_{789} 38.8°, n_D^{25} 1.3869, therefore should not exhibit additive abnormality nor should it be susceptible directly to solvent influence. From the theoretical viewpoint (cf. preceding abstr.) I may not only manifest a direct peroxide but also a direct solvent effect. I is therefore used to exam. experimentally these theoretical interpretations. HBr is added to I under various conditions with the following results: Ascaridole (II) causes the formation of the abnormal secondary isopentyl bromide (III). The extent of this effect increases with the concn. of II. Contrary to K., therefore, the abnormal addn. is not limited to 1-alkenes. In CS_2, C_5H_{12} and AcOEt at −78°, HBr and I give the normal Me_2CBrEt (IV). In Et_2O at −78°, I and HBr yield III in a considerable proportion which increases with rising temp. It is reduced only slightly by the presence of "antioxidant" Ph_2NH (V) but to a large extent by p-$C_6H_4(OH)_2$ (VI). Under the same conditions I and HCl or HI yield only the tertiary amyl halides. AcOH induces the formation of a small proportion of III. The abnt., not affected by the presence of II, is reduced slightly by V and completely by VI. In Me_2CO soln. the addn. yields only IV, as it does also in the presence of II. MeOH and EtOH effect a small percentage of the abnormal addn. at −78° which decreases with rising temp. In these solvents II causes a large proportion of the abnormal addn. at −78° but its effect falls off with rising temp. and at 20° it has no measurable influence on the normal course of the reaction. The chem. mechanism of the peroxide effect, as advanced by K., is not applicable to explain the above results of certain solvents in causing the abnormal addn. or to interpret the specific combined effect of solvent and peroxide. This interpretation has been discussed. It has been shown that in the abnormal addn. to I, the relations between solvent effect and peroxide effect vary decidedly when used separately and together. The abnormal effect of solvents on the addn. of HBr to I is specific, depending upon their chem. character. In certain solvents II exercises a marked effect upon the course of the addn. while in other solvents it remains inert. The influence of V as "antioxidant" depends upon the nature of the solvent and may be practically ineffective in reducing the abnormal addn. which is usually suppressed by VI. In some solvents, however, this effect is only partial and depends upon the temp. These relations differ to a considerable extent from those observed in the corresponding reaction with 1-alkenes. An explanation of the abnormal addn. of HBr to I by solvent influence is advanced, based upon the primary formation of double mols. of HBr and solvent. These then unite, in accordance with the partition principle, with the relatively more pos. unsatd. C in the alkene and the reversal occurs when the formed unsatd. C-solvent-HBr grouping functions as relatively neg. to the terminal, formerly relatively neg., unsatd. C. A corresponding chem. change is believed to take place in the addn. reversal by peroxide effect.
F. E. Brauns



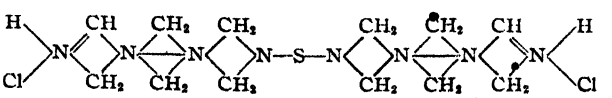
A new method for the separation of organic oxygen compounds from hydrocarbons. A. S. Osokin. *J. Gen. Chem.* (U. S. S. R.) **9**, 1315–25(1939).—The method, based on the reaction of O-contg. compds. with $MgCl_2$ to form complexes of the oxonium type, is suitable for the quant. sepn. of neutral O-contg. compds. (alcs., aldehydes, ketones, esters, lactones, anhydrides, etc.) from hydrocarbon mixts. Phenol ethers, and furan and pyran compds. which do not contain OH, CO_2H or carbonyl groups fail to form complexes. The following mixts. in petr. ether (30–70°) were refluxed with $MgCl_2$ and the corresponding complexes (cf. *C. A.* **33**, 1263[7]) isolated and analyzed. The values in parenthesis denote the amts. in % of O-contg. compds. removed from soln. AmOH(I)-Me_2CO (II) (99.49), I-AcOAm (III) (98.72), I-furfural (IV) (99.12), I-Ac_2O (V) (99.52), I-II-III (93.69), I-III-V (98.99), I-II-V (94.10), II-III-V (99.30), I-III-IV (98.88) and I-II-IV-V (97.52).
John Livak

Alkyl peroxides. XII. Ethylidene diperoxide. Alfred Rieche and Richard Meister. *Ber.* **72B**, 1933 8(1939); cf. *C. A.* **29**, 6877[4]. Previous work has shown that almost all aldehyde analogs of peroxides can be prepd.; only monomeric aldehyde or ketone peroxides of the general structure $RHC\langle^{O}_{O}\rangle$ and $RR'C\langle^{O}_{O}\rangle$ are unknown and, the authors believe, are incapable of existence; all the "monomeric" aldehyde peroxides which are described in the literature have been erroneously assigned such a structure. If they are actually formed transiently in any reaction it is to be expected that they will immediately dimerize or change into polymeric cyclic peroxides or carboxylic acids (cf. R., *Die Bedeutung der organischen Peroxyde fur die chemische Wissenschaft und Technik*, p. 16; *C. A.* **31**, 700[1]). Aldehydes with 1 mol. H_2O_2 form hydroxyalkyl hydroperoxides which yield alkylidene peroxides with dehydrating agents. A polymeric ethylidene peroxide (I) was prepd. in this way from MeCH(OH)OOH (II) and P_2O_5 in ether (*C. A.* **26**, 82). Wieland and Wingler (*C. A.* **17**, 2558) by heating bis(α-hydroxyethyl) peroxide or letting it stand a long time obtained a highly explosive resin which they considered to be dimeric I but which R. and M. regard as a polymer. However, they believe both this and their own product contained certain amts. of the dimer, which they undertook to prep. in a pure and nondangerous form. They tried to eliminate water from II in Me_2O at a considerably lower temp. than that which results in the formation of the polymeric I but the reaction proceeded in an entirely different direction; 2 mols. of the II esterified each other to form *bis(hydroperoxyethyl) ether*, $[MeCH(OOH)]_2O$. An unexpected result was obtained in connection with the prepn. of monoperparaldehyde (III) from the so-called "synthetic dimeric butylene ozonide" (*C. A.* **26**, 5906). When the latter substance is cautiously heated *in vacuo* it undergoes cleavage (which was considered to be a "cracking" of the labile 10-membered ring) and III distils over. In one such "cracking" operation, after the III had distd. over under 14 mm. at a bath temp. of 60–70° there formed, at about 80°, in the condenser and receiver a white cryst. mass which, unlike III, was extremely explosive. A minute crystal readily penetrated through a clay plate, with a flash of fire, when pressed with a metal spatula. The felted needles, dissolved out with ether, cautiously evapd., filtered and washed with ether, yielded pure *dimeric* I. The substance has a penetrating, AcH-like odor; a small sample on a watch glass evaps. in about 10 min. Its prepn. is always reproducible but violent detonations frequently occur so that only small amts. of materials must be employed and only with the greatest possible precautions. It is cer-

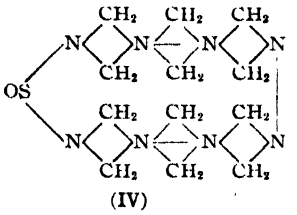


tainly possible to convert the oil remaining after distn. of the III, which consists chiefly of polymeric I, for the most part into the dimer, for more and more of the latter passes over as the heating is continued, but the residual oil becomes increasingly sensitive so that even a slight jar may cause it to detonate. The largest amt. of the dimer which has been prepd. at any one time was 500 mg. M. m. 63° without decompn., mol. wt. 117 (boiling benzene), 123–7 (dioxane); C and H detns. by the Pregl micro method and C detns. by the Lieb and Krainich wet combustion method gave values agreeing with the formula $(C_2H_4O_2)_x$. The dimer is relatively stable toward hydrolytic agents; it is not appreciably decompd. by long heating with water and even with 25% H_3PO_4 it can be heated for hrs. on the water bath without change. It is insol. in water but sol. in most org. solvents. Its oxidative power is remarkably small. Iodometric titration in alc. gave only 2.7% active O instead of the calcd. 26.7%, and even titration in ether with aq. $TiCl_3$ gave only 1%. **XIII. Tripropylidene triperoxide.** *Ibid.* 1938–40.—$[EtCH(OH)]_3O_2$ (I) had been found (R., *Alkylperoxyde und Ozonide*, p. 57; *C. A.* **25**, 1258) to undergo a change whereby it becomes explosive and richer in active O; the change was accelerated by allowing an ether soln. to stand over P_2O_5 and evacuating the residue for a long time. It was believed that tripropylidene triperoxide (II) was formed through an intermediate mononeric or dimeric propylene ozonide which split off EtCHO, the resulting propylidene peroxide then trimerizing. The process would thus be entirely analogous to the formation of dimeric and polymeric ethylidene peroxide (Part XII above). It had not been possible, however, to repeat the prepn. of pure II by the above method; I with P_2O_5 in ether gave oils whose compn. corresponded approx. to that of propylene ozonide and which on heating *in vacuo* gave off EtCHO and underwent further change, but the products were not homogeneous. The method used for ethylidene peroxide was not successful in this case. II was obtained without difficulty, however, by elimination of water from EtCH(OH)OOH. When equimol. amts. of H_2O_2 and EtCHO were allowed to stand some days in ether and the soln. was treated a long time with P_2O_5 at 0 5°, evapn. of the ether and heating the residue *in vacuo* gave an oil somewhat more mobile than glycerol, with a penetrating odor similar to that of ethylidene peroxide, and which was exceedingly explosive, although not so brisant as the dimeric ethylidene peroxide. It was also very sensitive to friction; the slightest pressure on a drop on a clay plate produced detonation. II is insol. in water but easily sol. in most org. solvents, has the compn. $(C_3H_6O_2)_x$ (Pregl), d_{20} 1.089, n_D^{20} 1.43903, mol. refr. 53.612, exaltation 2.195 (0.73 per peroxide group), mol. wt. in dioxane 215, surface tension at 20° 32.94 dynes/cm., parachor 438.8 (calcd. 487.8; the increment for peroxide O has been found to be 21.3). According to Mumford and Williams a ring const. of −4 in the parachor value corresponds to about a 7-membered ring; in view of the inexactness of the method, the value found can equally well indicate a 9-membered ring. The ring in II is less resistant to hydrolysis than the 6-membered ring of dimeric ethylidene peroxide, but complete hydrolysis with acids to EtCHO and H_2O_2 is not possible. By the iodometric method, only about half the calcd. amt. of H_2O_2 is found. With alkalies the greater part (about 75%) goes over into $EtCO_2H$.

C. A. R.



The structure of hexamethylenetetramine. The action of chlorides of sulfur upon formine. Preliminary communication. Mieczysław Dominikiewicz. *Arch. Chem. Farm.* **4**, 1–7 (in French, 7) (1939).—The reactions between formine (hexamethylenetetramine) and SCl_2, S_2Cl_2, as well as $SOCl_2$ and SO_2Cl_2, were studied. These reactions take place very easily, similarly to the reaction of formine with $COCl_2$ (cf. *C. A.* **32**, 4522[4]). The S compds. in $CHCl_3$ are run into formine in cold $CHCl_3$; white, cryst. products of the reactions ppt. almost quantitatively. They are purified by crystn. from MeOH. With all the above-mentioned chlorides of S, formine gives the same Cl compd., characterized by a m. p. of 193–4°. This compd. has the chem. formula $(CH_2)_6N_4Cl$ (I) and its properties are identical with those of the product of the reaction between $COCl_2$ and formine; its aq. soln. is acid and it can be titrated; the same holds for the alc. soln. The soln. ppts. AgCl from an $AgNO_3$ soln. The aq. and alc. solns. conduct electricity. The reactions between formine and the S compds. in question can be expressed by the scheme:



where X = -S-, -S-S-, -SO- or $-SO_2-$. The chem. constitution of I can be represented by a tautomeric formula (II), which explains the ionization of $(CH_2)_6N_4Cl$ in solns. According to this formula, being in accord with the formula of formine adopted by D. (cf. *C. A.* **30**, 1029[8]), the compd. formed by interaction of formine and the Cl compds. of S is chlorodiformine (II). With SCl_2, besides II, another compd. was also sepd.; its analysis seems to prove that it is thiochlorodiformine (III). This compd. is sol. in water and gradually sets free its S. In the reaction between $SOCl_2$ and formine, besides II a 2nd compd. was also sepd. Its analysis permits the assumption that it is thionyl diformine (IV). By the action of SO_2 upon formine in $CHCl_3$, an addn. product of formine and SO_2 was obtained; it has the formula $(CH_2)_6N_4.SO_2$. It is a cryst., snow-white compd., very highly hygroscopic and very easily sol. in MeOH and EtOH; exposed to the air, it becomes moist and liberates SO_2; its aq. solns. are acid; on heating they emit CH_2O. It is possible that this compd. is also formed besides II in the action of SO_2Cl_2 upon formine. It could not be sepd., however, by crystn. from MeOH, as it is too sol. and it decomps. on contact with moisture. Further investigations are being carried on.

Hydrogenation of acetone. Bruno Foresti. *Atti XXVII riunione, Bologna, Soc. ital. progresso sci.* 5, 346–52 (1939).—Hydrogenation of acetone in aq. soln. contg. Na_2SO_4 and at ordinary temp. and pressure results in the formation of propane and iso-PrOH (in the presence of Pt black) if the soln. is acidic and the alc. alone, with traces of diacetone glycol, if the soln. is alk. In no case does pinacol form. Under these conditions pinacol and iso-PrOH cannot be hydrogenated. It is suggested that the mechanism differs from that of the electrolytic reduction of acetone. H. A. Iredale

The dissociation constants of monocarboxylic acids; their measurement and their significance in theoretical organic chemistry. John F. J. Dippy. *Chem. Rev.* 25, 151–211(1939). The methods used in measuring the strengths of org. acids are reviewed and the effect of constitution on dissocn. consts. is discussed. Many references are given. The appendix contains all of the dissocn.-const. data for monobasic org. acids (also phenols and bases) that have been derived by the modern, more reliable methods. Louise Kelley

Synthesis of diallylacetic (heptadiene-4-carboxylic) acid. M. Dominikiewicz and M. Krjewska. *Arch. Chem. Farm.* 4, 41–4(in French, 44)(1939). The Na deriv. of acetoacetic ester gives with allyl bromide the monoallyl deriv. of the ester. In the latter the 2nd H atom is substituted with Na, and it is made to react with a 2nd mol. of allyl bromide; diallylacetoacetic ester is formed. On sapon. this yields the free acid, $(CH_2{:}CHCH_2)_2CHCO_2H$ (I); at the same time, however, a certain quantity of diallylacetone (II) is formed. Hitherto, in this sapon. almost equal quantities of I and II were obtained. The authors describe in detail how to conduct this sapon. so as to obtain I in 75% yield. 7 references. Edward A. Ackermann

The synthesis of α-amino alcohols from the light oil fraction obtained in the pyrolysis of gas oil and determination of some of the hydrocarbons entering into its composition. L. S. Dedusenko. *J. Gen. Chem.* (U. S. S. R.) 9, 1294–1302(1939). The light oil, b. 27–50°, d^{15} 0.7464, shown to contain 3.5–3.7% cyclopentadiene, was treated with HOCl and the aq. soln. of chlorohydrins distd. over KOH to give 28.6–30.6% of mixed oxides, which was increased to 37.9–41% when NaOH was used. The mixt., b. 60–140°, contg. approx. 50% amylene oxides, with 10 vols. 25% NH_4OH in sealed tubes at 100° for 6–7 hrs. gave 63.8% (based on amylene oxide, 19% based on amylene) of crude amino alcs., from which was isolated $Me_2C(OH)$-$CH(NH_2)Me$ (I), b. 156–8°, as the *picrate*, m. 133.5–4.5°; *acid oxalate*, m. 119° (turbid), 121–2° (decompn.); *oxalate*, m. 210.0–10.5° (decompn.). The other amino alcs. in the mixt. could not be identified since their acid oxalates were chiefly oils while the neutral oxalates were cryst. but could not be sepd. Ether extn. of the alk. residues from the distn. of the oxides gave a mixt. of glycols from which were sepd. by distn. $Me_2C(OH)CH(OH)Me$ (II), $MeCH(OH)CH(OH)Et$ (III) and *cis*-cyclopentadiol (IV). II and III were identified by dehydration to Me(iso-Pr)CO (semicarbazone, m. 111–12°), and Et_2CO (semicarbazone, m. 135°), resp. IV with PhNCO (V) gave the urethan $C_{19}H_{20}N_2O_4$, m. 211–12°. Treatment of the mixt. of glycols with V led to the formation of PhNCO polymers, probably because of the presence of halogen-contg. impurities. II, b. 176–9°, prepd. from the oxide, gave with 2.04 moles V the urethan $C_{19}H_{22}N_2O_4$, m. 134.5–5.5°, and with 0.625 moles V gave the partial urethan $C_{12}H_{17}NO_3$, m. 125.5°. Conclusion: $Me_2C{:}CHMe$, $MeCH{:}CHEt$ and cyclopentene are present in the light oil fraction analyzed. John Livak

The reagents of Girard and Sandulesco. Applications to the separation of ketonic fractions. A. Petit and Suzanne Tallard. *Rev. chim. ind.* (Paris) 48, 226–31(1939). —The 2 quaternary salts, $Me_3NClCH_2CONHNH_2$ (I) and $C_5H_5NClCH_2CONHNH_2$ (II), are used for the isolation of ketonic substances such as hormones, vitamins and perfumes because of their property of forming with these ketonic compds. combinations which are water-sol. and are not sol. in nonhydroxylic org. solvents. To 984 g. of $ClCH_2CO_2Et$ (III) in 1000 cc. of abs. EtOH is added 280 g. of NMe_3 (previously cooled to −5°). The reaction starts immediately and the temp. rises to about 60°. After 24 hrs. at room temp. 400 g. of 100% $N_2H_4.H_2O$ is added. An exothermic reaction sets in and after 45 min. of agitation the soln. is cooled and the product is crystd. and dried in a desiccator over H_2SO_4. Yield, 1100 g. of I (90% of theory). I is very hygroscopic and develops a disagreeable odor if it becomes moist. Pyridine (632 g.), 2000 cc. abs. EtOH and 984 g. of III are refluxed 2–3 hrs. until the odor of III disappears. A sample should dissolve completely in dil. H_2SO_4. After cooling, 400 g. of $N_2H_4.H_2O$ in 500 cc. of abs. EtOH is added. An exothermic reaction occurs. The crystals are filtered from the alc. and dried in air. Yield, 90% of theory of II. II is not hygroscopic. For extn. of ketone bodies, 5–10% of I or II is mixed with the ketones (in alc.) and 10% AcOH is added. After refluxing for 0.5–1 hr., the soln. is cooled and the AcOH is partially (90%) neutralized to a definite pH. The resulting mixt. is cooled and the nonketonic compds. are extd. with Et_2O or $(iso\text{-}Pr)_2O$. The remaining aq. soln. of the ketones combined with I or II is then hydrolyzed with HCl or H_2SO_4 and the ketone extd. Some difficulty may be encountered in sepg. the complex of the ketone and I or II from the nonketonic compds. because of the emulsifying tendencies of I and II. The utilization of I and II for the extn. of folliculin (estrone), the corticoadrenal hormone, isomenthone, methylheptenone, vitamin E and other ketones is cited. R. F. D

Synthesis of choline esters. Dimorphism of the higher terms. Maurice Loury. *Compt. rend.* 209, 682–4 (1939).— A convenient method of prepg. fatty acid esters of halogen salts of choline is by the action of MeX (X = Cl, Br or I) on the $Me_2NCH_2CH_2$ ester of the fatty acid: $RCO_2CH_2CH_2NMe_2$ (I) + MeX = $RCO_2CH_2CH_2NMe_3X$ (II), (R = $Me(CH_2)_n$). I is obtained by the action of the acid chloride on one or two mols. of aminoethanol, and in the former case treatment of the halogen salt with alc. KOH or AgOH: RCOX + $NMe_2CH_2CH_2OH$ = RCO_2-$CH_2CH_2NMe_2.HX$ (1) or RCOX + $2NMe_2CH_2CH_2OH$ = $RCO_2CH_2CH_2NMe_2$ + $CH_2(OH)CH_2NMe_2.HX$ (2) I with n = 10 or 14 are colorless oils, b_3 155° and 187°, resp., with n = 16 a white fat, m. 25°, b_3 205°. II usually form pearly greasy leaflets with no definite cryst. outlines; but by careful arrangements the palmitic-iodine deriv. (n = 14, X = I) is obtainable in either lozenge-shaped leaflets or transparent rectangular tables, but more frequently both forms are obtained together. The derivs. with n = 10 or 16 give only one or other form, as also do those with X = Br. The dimorphism thus resembles the polymorphism of other long-chain compds. C. A. S.

New syntheses of basic amino acids and glycine. Donald W. Adamson. *J. Chem. Soc.* 1939, 1564–8.— When α-aminodicarboxylic acids are submitted to the Schmidt N_3H reaction, the CO_2H group remote from the α-NH_2 group is replaced by an NH_2 group. Addn. of N_3H (4.8 g.) in 48 cc. $CHCl_3$ during 6 hrs. to 14.7 g. *d*-glutamic acid, 25 cc. concd. H_2SO_4 and 10 cc. $CHCl_3$ at 43–6° with stirring, which is continued for an addnl. 4 hrs., decompn. of the product with ice and pptn. with phosphotungstic acid gives 41% of *d*-α,γ-diaminobutyric acid (as the oxalate); NaN_3 gives 33% of the acid; *dipicrate*, yellow, m. 180–1°; *di-HCl salt*, m. 195–6° (decompn.), α_D^{19} 14.6° (H_2O, *c* 3.67). α-Aminopimelic acid (I) gives 66% of *dl*-lysine (as the monopicrate); NaN_3 gives a 55% yield; *dipicrate* (II), yellow, m. 188–90°. Passing a slow stream of dry HCl through Et cyclohexanone-2-carboxylate (III)

in C_6H_6 contg. 1.4 moles N_3H in an ice bath for 3 hrs., adding concd HCl and boiling the dild. aq. layer for 3 hrs. gives 8% of I and 18% of II; at 3–5° in $CHCl_3$ there results 25% of II; the use of 2 moles N_3H gives 60% of II. III and N_3H in concd. H_2SO_4 give only a trace of II. α-Aminoadipic acid and N_3H in $CHCl_3$ and H_2SO_4 give 75% of *dl*-ornithine (as sulfate); Et cyclopentanone-2-carboxylate gives 40% of the acid. Adding 2.4 g. N_3H in 35 cc. $CHCl_3$ during 2 hrs. to 5.2 g. $CH_2(CO_2H)_2$ in 15 cc. H_2SO_4 at 40° gives 29% of glycine; at 50° the yield is 46%. A convenient method for the isolation of basic amino acids is through the use of the dipicrates. The above reaction appears to be a general method for the synthesis of such acids. Cf. Brit. pat. 307,798, *C. A.* **24**, 127; Fr. pat. 671,388, *C. A.* **24**, 2140; Ger. pat. 544,890, *C. A.* **26**, 3515. C. J. West

Behavior of the SCH$_3$ group in methoxyl determinations. Fritz Arndt, Lotte Loewe and Mehke Ozansoy *Ber.* **72B**, 1860–3(1939).—Baernstein's method for the detn. of MeS in methionine (*C. A.* **30**, 7136[1]) is essentially the same as the Vieböck and Schwappach method for detg. MeO as modified by Clark (*C. A.* **26**, 2395). With pure methionine the present authors by the usual Vieböck semimicro method obtained the calcd Me value after 3 hrs. heating (the customary 1.5 hrs. heating gave only 4/5 of the calcd. value). The MeS group in methionine and its derivs. is therefore hydrolyzable like almost all MeO groups, although with somewhat greater difficulty. But this is not true of all MeS groups. *p*-MeC_6H_4SMe even after 8 hrs. gave only about 1/3 of the calcd. Me value. On a preparative scale, no free MeC_6H_4SH could be detected in the reaction mixt. after 7 hrs. boiling with azeotropic HI; unsolar as slow hydrolysis occurs, there is a further decompn. of the free mercaptan. With AcSMe and *S*-methylthiuronea sulfate, still lower results are obtained. On the other hand, the MeS group in thiomazole Me ether and its 5 Ph deriv. behave entirely like MeO, giving the calcd Me values after 1–1.5 hrs. and smoothly yielding the free mercaptans in preparative expts. Dithiourazole di-Me ether gives values corresponding to 1.5 and 2 Me groups after 1.5 and 5 hrs., resp., whereas the structurally closely related aminothiobiazolethiol Me ether gives only 1/3 and 1/2 of the calcd. values after 4 and 6 hrs., resp. There is as yet no clear relationship between structure and behavior of MeS groups toward HI, and if it is desired to det. MeO groups in a compd. also contg. MeS groups a blank will have to be made on the mother substance (contg. the MeS groups only). C. A. R.

Methionine IV. A color reaction of methionine. Joseph J. Kolb and Gerrit Toennies. *J. Biol. Chem.* **131**, 401–7(1939); cf. *C. A.* **33**, 7833[7].—Methionine and certain closely related substances form a compd. with a deep orange-brown color with solns. of $CuCl_2$ in concd. HCl. The compd. is stable in concd. HCl and is a combination of 1 mol. each of methionine-HCl and $CuCl_2$. Methionine is the only commonly known amino acid which gives this reaction. A. P. Lothrop

Hydroxy aldehydes. III Preparation of δ-methoxyvaleraldehyde. Rudolf Pummerer and Matthäus Schönamsgruber. *Ber.* **72B**, 1834–43(1939); cf. *C. A.* **29**, 3653[4].—It was shown in the earlier papers that in the formation of levulinic acid from hexoses with boiling acids there occurs a remarkable inner dismutation of δ-hydroxylevulinaldehyde and that the δ-MeO aldehyde, as also $MeOCH_2CH(OH)CH_2CH_2CHO$, undergo the same dismutation. For comparison with these aldehydes, simpler HO and MeO aldehydes, e. g., the as-yet unknown *δ-methoxyvaleraldehyde* (I), were of interest. The present paper describes the prepn. of I. Two methods were used. (1) From 300 g. $CH_2(CH_2OH)_2$ and 28 g. Na with 175 g. MeI on the water bath was obtained 98 g. $MeOCH_2CH_2CH_2OH$, b_{738} 150–0.5°, b_{18} 76–68° (so given in the original; crude product, b_{14} 58–61°), d_4^{20} (vac.) 0.9455, n_D^{20} 1.41292; *anthraquinone-β-carboxylate*, from the ether cautiously heated over a small flame with the calcd. amt. of β-$C_6H_4(CO)_2C_6H_3COCl$ until the evolution of HCl ceased, m. 132° (m. ps. cor.). The ether (240 g.) in 42 g. pyridine treated in the course of 4 hrs. with 322 g. PBr_3 gave 135 g. $MeO-CH_2CH_2CH_2Br$ (II), b_{18} 29–30°, b_{736} 129.5–31°, d_4^{20} (vac.) 1.3592, n_D^{20} 1.44667. Attempts to obtain the phthalimide from $C_6H_4(CO)_2NK$ and the calcd. amt. of II at 190° gave only *trimethylene diphthalimide*, m. 202°. With somewhat more than 1 equiv. of titrated $CH_2{:}CHCH_2MgBr$ soln., II gave *6-methoxy-1-hexene* (56 g. crude product from 120 g. II), freed from unchanged II by refluxing in pyridine at 120 30°, decanting from the viscous deposit, distg., pouring the distillate into enough aq. H_2SO_4 (1 5) so that the pyridine odor disappeared, sepg. the upper layer, shaking it out with a little ether, drying with Na_2SO_4 and fractionating. The pure III (45 g.) b_{742} 124°, d_4^{20} (vac.) 0.7916, n_D^{20} 1.41173. From 20 g. III ozonized in AcOH and, after dilu. with ether, treated with Zn dust was obtained 15.5 g. I, $b_{14.5}$ 59°, d_4^{20} (vac.) 0.9198, n_D^{20} 1.41625, mobile oil of penetrating ether-like odor and very burning astringent taste, sol. in about 3 parts water, shows all the typical reactions of free aldehydes (immediate reduction of cold NH_3-$AgNO_3$, strong reduction of hot Fehling soln., strong reddening of fuchsin-SO_2 in a few sec.), gives a cryst. ppt. with 2,4-$(O_2N)_2C_6H_3NHNH_2$, is easily volatile with steam, dissolves with strong evolution of heat in $NaHSO_3$ and in MeOH, dissolves clear in concd. HCl and with brown color and green fluorescence in concd. H_2SO_4, gives with phloroglucinol in concd. HCl a lake-colored amorphous ppt. becoming white on dilu. with water, and with resorcinol in concd. HCl a white amorphous ppt. In the liberation of I from its $NaHSO_3$ compd. with concd. alkali aldol condensation occurs; there is obtained a product b_{14} 152° (decompn.). Probably there is a partial elimination of water to form *2-(ω-methoxypentenyl)-5-methoxy-1-pentanal*, for the difficultly water-sol. oil of pleasant ethereal odor immediately decolorizes Br and gives all the above aldehyde reactions and a yellow ppt. with phloroglucinol-HCl. *Di-Me acetal* of I, b_{16} 81.5°, d_4^{20} (vac.) 0.9247, n_D^{20} 1.41456, reduces hot Fehling soln. only after short boiling with acids, reddens fuchsin-SO_2 after some min. and reduces NH_3-$AgNO_3$ slowly at room temp. I showed quite normal stability and preliminary attempts to dismutate it to valeric acid by the same means as convert δ-methoxylevulinaldehyde into levulinic acid have thus far given no conclusively pos. results. (2) After the properties of I had been learned, its prepn. was effected by a simpler method from com. 1,5-pentanediol (IV). Oxidation of IV with hot acid $KMnO_4$ to det. the position of the HO groups resulted in the formation of HCHO, about 9% succinic acid and, as chief product, a yellow oil, b_{22} 130° (possibly valerolactone), but with 2% alk. $KMnO_4$ at room temp. was obtained more than 80% of almost pure glutaric acid, m. 95°. Furthermore, IV with PCl_5 in CCl_4 gave $Cl(CH_2)_5Cl$, b_{21} 76–8°, which with NaCN in MeOH yielded, through the dinitrile, pimelic acid, m. 104°. Diurethan of IV, m. 176°. *Bis(anthraquinone-β-carboxylate)*, pale yellow, m. 218.5°. *Mono-Me ether* (V) (70% from IV, Na and MeI), b_{17} 95°; the urethan and acid phthalate did not crystallize and decompd. on distn., but the *anthraquinone-β-carboxylate* formed greenish yellow rodlets, m. 88° (cor.). V (10 g.) with $K_2Cr_2O_7$ and H_2SO_4 gave 4 g. unchanged V, 0.6 g. I, b_{15} 60°, and 2 g. high-boiling aldol. C. A. R.

Synthesis of uronic acids. M. Stacey. *J. Chem. Soc.* **1939**, 1529–31.—Oxidation in AcOH with $KMnO_4$ converts 1,2,3,4-tetraacetyl-β-*d*-glucose to 1,2,3,4-tetraacetyl-*d*-glucuronic acid; the latter need not be isolated since by the action of $Ba(OH)_2$ in aq. soln. deacetylation with simultaneous formation of Ba glucuronate takes place readily; removal of the Ba and crystn. from EtOH gives 20% of the acid (based on the glucose used as starting material). Similarly *d*-galacturonic acid can be prepd. in approx. 20% yield from *d*-galactose. C. J. West

Mercury salts as catalysts in the synthesis of aspartic acid from fumaric acid and ammonia. Terje Enkvist and Laura Laasonen. *Ber.* **72B**, 1927–32(1939).—The catalytic influence of simple inorg. substances on the formation of aspartic acid (I) by the addn. of NH_3 to fumaric acid (II) has been studied as a preliminary step in the investigation of org. catalysts with aspartase action (*C. A.* **32**, 2816[7]). The catalytic action of various substances,

especially metal salts, was detd. by measuring either the increase of amino N by the Van Slyke nitrite method, after removal of the ammonia N by evapn. with $Ca(OH)_2$, or the decrease in $KMnO_4$ consumption in H_2SO_4 at about 55°. Little or at most very little catalytic activity was shown by Cl, Br, I, $FeSO_4$, PbO; $KCr(SO_4)_2$ and $FeCl_3$ with Seignette salt (III) (amino-N method); $CoSO_4$, $Ni(NO_3)_2$, $[Co(NH_3)_4CO_3]_2SO_4$, $CuSO_4$, $CdCl_2$, $PdCl_2$, H_2PtCl_6, $Pb(NO_3)_2$, $MnCl_2$ and $KHCO_3$ without III ($KMnO_4$ method). On the other hand, mercuric oxide, chloride and sulfate materially accelerated the reaction ($KMnO_4$ method); $HgCl_2$ also gave a pos. result by the amino-N method. A weaker but still distinct effect was shown by $AgNO_3$. The action of $HgCl_2$ was not increased by piperidine, $NHEt_2$, pyridine and $NCCH_2CONH_2$ ($KMnO_4$ method). Substitution of $(NH_4)_2CO_3$ soln. for NH_4OH gave poor yields of amino N. In the main expts. the I was isolated as the Cu salt. The favorable action of mercuric compds. and $AgNO_3$ was confirmed; mercuric chloride, oxide and sulfate were approx. equally active per equiv. One mol. of $HgCl_2$ can increase the yield of I by about 3 mols. The effect is about proportional to the amt. of catalyst. With moderate amts. of catalyst the II has for the greater part disappeared after 9 hrs. at 100° and practically completely after 33 hrs. Judging from the behavior of the nitrate, mercurous salts accelerate the reaction only insofar as they are converted into mercuric salts; 2 mols. have about the same effect as 1 mol. of mercuric salt. NaOH, both in the presence and in the absence of mercuric salts, has an inhibiting action on the formation of I, as does CuCl. The influence of $HgCl_2$ on the addn. of NH_3 to maleic acid (IV), which without a catalyst adds NH_3 more rapidly than II, was also tested; the result was neg. Neg. results were also obtained in preliminary expts. on IV (amino-N method) with $MnCl_2$ in the presence and with I in the absence of ascorbic acid. The fact that mercuric compds. form isolatable addn. products with IV but not with II would seem to indicate that the catalysis is due to an activation of the II, not the NH_3, by the formation of a labile complex; with IV, the formation of an unreactive, too stable adduct inhibits the catalysis. The catalytic effect of the Ag ion, which, like the mercuric ion, forms a complex with NH_3, suggests, to be sure, that the power of the metal ion to combine with NH_3, may play a role in the catalysis. Possibly the fumarate ion, metal ion and NH_3 form an unstable complex which then decomps. into aspartate ion and an NH_3-free or NH_3-poor metal ion. In the expts. with $HgCl_2$, I was obtained through the Cu salt in good yields (3.9 g. completely crystd., almost colorless product and 0.7 g. yellowish but still solid product from 10 g. II); after 2 crystns. from hot water it m. 227–8° (decompn.) in sealed tubes. In another expt. the I from 10 g. II was esterified with EtOH-HCl, giving 3.4 g. di-Et ester, b_{12} 125.5–7.5°, d_4^{20} 1.0815, n_D^{20} 1.4378. C. A. R.

The chemistry of aminoguanidine and related substances. Eugene Lieber and G. B. L. Smith. *Chem. Rev.* **25**, 213–71(1939).—A review with many references.
Louise Kelley

Syntheses according to Friedel-Crafts with tricarballylyl chloride and α-phenyltricarballylyl chloride. Walther Borsche and Helmut Schmidt. *Ber.* **72B**, 1827–33(1939). —Succinyl chloride in the Friedel-Crafts reaction reacts chiefly in the unsym. form, $O.CO.CH_2.CH_2.CCl_2$, giving mainly γ,γ-diaryl-γ-butyrolactones, along with a little of the 1,4-diketones (*C. A.* **31**, 387[8]). A study has been made of tricarballylyl chloride (I) to det. whether it behaves in the same way. With benzene, 23.1 g. I gave 2 compds. of formula $C_{24}H_{20}O_3$: 23 g. *α-phenacyl-γ,γ-diphenyl-γ-butyrolactone* (II), yellowish needles, m. 137–8°, sol. in aq. alc. KOH or K_2CO_3 only on long boiling and repptd. unchanged by HCl (*oxime*, m. 203–5°; *2,4-dinitrophenylhydrazone*, orange-yellow, m. 219–21°; *Br deriv.*, from II and Br in AcOH at 100–10°, m. 141–2°; *4-(ω-diphenyl-ω-hydroxyethyl)-6-phenyl-3-oxo-2,3,4,5-tetrahydropyridazine*, $CO.NH.N:CPh.CH_2.CHCH_2CPh_2OH$, from II and N_2H_4.-H_2O boiled 12 hrs. in MeOH, m. 195–6[5]), and about 3 g. of the *β-phenacyl isomer*, m. 108–10° (*2,4-dinitrophenylhydrazone*, m. 159–61°). II had already been prepd. by Emery (*Ber.* **24**, 601(1891)) who, however, described it as $BzCH(CH_2Bz)_2$. With toluene the reaction was more complex; in different expts. under as nearly identical conditions as possible the results were not always the same. In 2 runs the chief product from 23.1 g. I was a keto lactone (11–12 g.), presumably *α-tolacyl-γ,γ-ditolyl-γ-butyrolactone* (III), m. 133–4° (*2,4-dinitrophenylhydrazone*, yellow, m. 187–8°; *tetrahydropyridazine*, m. 201–2°), with 1.6 g. of an acid, $C_{20}H_{20}O_4$, (IV) which was not wholly freed from the keto lactone and was analyzed only as the *bis(2,4-dinitrophenylhydrazone)*, $C_{28}H_{28}O_{10}N_8$, orange-red, m. 208–10°. IV was most probably *ditolacylacetic acid*. In 2 other runs there were obtained, resp., instead of IV, 2 isomers: 7 g. *γ,γ-ditolyl-γ-butyrolactone-α-acetic acid* (V), m. 190–2°, and 6.5 g. of the *β-acetic acid* (VI), m. 116–17°. V was accompanied by 11–12 g. III, VI by 1.9 g. *dimethylanthracene*, m. 220° (the crude product gave with 2,4-$(O_2N)_2C_6H_3NHNH_2$ an orange-red product, m. 165–7°, with 9.76% N, possibly the *dinitrophenylhydrazone* of the *β-tolacyl* isomer of III). With *m*-xylene only 1 cryst. product could be obtained, presumably a *xylacyldixylylbutyrolactone* (15 g. from 23.1 g. I), m. 174–6°, sol. in dil. alc. KOH on long boiling. Some orienting expts. were also made with α-phenyltricarballylyl chloride. The tri-Et ester (20–5 g. from 17.2 g. di-Et maleate, 16.5 g. $PhCH_2CO_2Et$ and NaOEt on the water bath), b_{12} 212°, was sapond. in MeOH with aq. KOH to the acid (12 g. from 16.8 g. ester), m. (sealed capillary) 110–15°, resolidifies and again m. 195°. The acid (5 g.) was heated with an equiv. wt. of $SOCl_2$ and, without further purification, was treated with $AlCl_3$ in benzene, yielding 2.3 g. of an acid $C_{24}H_{20}O_4$, m. 230–3°, which formed no dinitrophenylhydrazone and was presumably one of the possible lactonic acids. C. A. R.

Zinc citrates. F. S. Shpilev. *J. Gen. Chem.* (U. S. S. R.) **9**, 1286–93(1939).—The formation and compn. of Zn citrates obtained by reaction of $ZnSO_4.7H_2O$ (I) with Na citrate (II) depend on the pH of the medium and on the amt. of II. I (14.38 g.) with an equimol. amt. of II (8.7 g.) in concd. H_2O soln. gives $Zn_3(C_6H_5O_7)_2$ (III). By heating the soln. prior to pptn. with alc., ZnO (IV) is also obtained. In alk. soln. both the OH and CO_2H groups react and the product is $Na_2Zn(C_6H_4O_7$ (V). In weakly alk. soln. the product is a mixt. of III, IV and V. In the presence of an excess of II the reaction proceeds in a different manner. I (14.38 g.) with 17.4 g. II gives, depending on the pH of the medium, $ZnNa_3H(C_6H_5O_7)_2$, $ZnNa_4(C_6H_5O_7)_2$ and $Zn(Na_3C_6H_4O_7)_2$, resp. The mechanism for the formation of the complexes is discussed.
John Livak

The constitution of the tetrameride of hydrogen cyanide. (A reply to the work of Hinkel, Richards and Thomas: "Studies on hydrogen cyanide. X. The tetrapolymer."). E. Gryszkiewicz-Trochimowski. *Arch. Chem. Farm.* **4**, 45–57(in English)(in Polish, 57)(1939); cf. *C. A.* **33**, 1383.—The expts. of G. and those of H., R. and T. (cf. *C. A.* **31**, 7848[9]) indicate irrefutably that the tetrapolymer of HCN possesses an aptitude for chem. conversions inducing the formation of heterocyclic rings. All those conversions can be easily explained by adopting for the tetrameride the structure of diaminomaleonitrile, $\begin{matrix} NH_2—C—CN \\ \| \\ NH_2—C—CN \end{matrix}$, proposed by G. some years ago. On the other hand, the formula of H., R. and T., who consider the tetrameride as an aminoiminosuccinonitrile, $\begin{matrix} NH_2—CH—CN \\ \| \\ HN{=}C—CN \end{matrix}$, is not only devoid of any convincing exptl. data, but moreover it possesses this weak side, that it does not explain the reaction of the tetrameride with HNO_2, glyoxal, etc. If one assumes, however, as H., R. and T are obliged to do, that in these latter reactions isomerization takes place, inducing the migration of an H atom and the rearrangement of the double bond, then it would be more proper to

assume that the grouping $\begin{matrix}-C-CN\\ \|\\ -C-CN\end{matrix}$ exists already in the tetrameride mol.; in consequence one arrives at the formula proposed by G. When comparing both formulas, one can easily notice that they may be considered as desmotropic varieties. However, the existence of the form corresponding to the formula of H., R. and T. is not sufficiently founded. 12 references. Cf. G., *C. A.* **22**, 4475.

Qualitative organic analysis. II. Identification of alkyl halides, aromatic nitroso compounds, aromatic hydrocarbons and cyclopentadiene compounds. Winifred J. Levy and Neil Campbell. *J. Chem. Soc.* **1939**, 1442–6; cf. *C. A.* **32**, 5009.—Brown and C. (part I) showed that alkyl bromides and iodides can be satisfactorily identified as alkylisothiourea picrates; the method has been extended to include chlorides and tertiary compds. Thiourea (1 g.) and 1 g. of the halide in 100 cc. EtOH are refluxed for various periods, picric acid added and the mixt. heated until a clear soln. results; H_2O may be added to facilitate pptn. of the picrate. *tert*-Bu and isovaleryl halides give the Et deriv. because of interaction with the solvent; $ClCO_2Et$ and $ClCO_2Me$ give the Et and Me derivs., resp. In the following the halide, the time of heating and the m. p. of the picrate are given: MeI 5 min., m. 224°; EtI 5 min., 188°; $C_2H_4Br_2$ 15 min., 260°; PrBr 5 min., 177°; PrCl 5 hrs., 176°; iso-PrBr 3 hrs., 196°; propylene dibromide 40 min., 232°; BuBr 5 min., 177°; BuCl 2 hrs., 177°; iso-BuI 10 min., 167°; *sec*-BuI 10 min., 166°; *tert*-BuI 3 hrs., 188°; isobutylene dibromide 1 hr., 223°; AmBr 20 min., 154°; AmCl 2 hrs., 154°; iso-AmBr 20 min., 173°; iso-AmCl 2 hrs., 173°; *sec*-AmBr 40 min., 157°; hexyl bromide 20 min., 157°; heptyl bromide 20 min., 112°; octyl bromide 20 min., 134°; cetyl iodide 3 hrs., 137°; allyl chloride 5 min., 155°; $(CH_2)_3Br_2$ 5 min., 229°; $McPhCHCH_2Br$ 5 min., 167°; $PhCH_2CH_2Br$ 5 min., 139°; *o*- and *m*-$BrC_6H_4CH_2Br$ 5 min., 222° and 205°; *p*-$BrC_6H_4CH_2Cl$ 5 min., 219°; *o*-, *m*- and *p*-$ClC_6H_4CH_2Br$ 5 min., 213°, 200° and 194°. The CH_2 group in 2,7-dibromofluorene condenses readily with C-NO compds. but the products are difficult to purify, probably owing to formation of both anils and nitrones. 2-Phenylindole forms anils suitable for identification of PhNO and *m*- and *p*-derivs. The azo compds. formed from NO compds. and *p*-$BrC_6H_4NH_2$ are the most suitable derivs. for identification. *3-Arylimino-2-phenylindolenines* (m. p. of NO deriv. given): Ph 154°; *m*- and *p*-ClC_6H_4 148° and 157°; *m*- and *p*-BrC_6H_4 169°, 154°; *m*- and *p*-MeC_6H_4 136° and 146°; these are all orange except the Ph deriv., which is vermilion. Substituted *p-bromoazobenzenes* (m. p. of NO deriv. given): Ph 88°; *o*-, *m*- and *p*-ClC_6H_4 110°, 119° and 190°; *o*-, *m*- and *p*-BrC_6H_4 104°, 126° and 205°; *o*-, *m*- and *p*-MeC_6H_4 82° and 152°; 0.1 g. of NO compd. can easily be identified by this method. 2,4,5-$(O_2N)_3C_6H_2Me$ is a valuable reagent for alkyl but not for aromatic amines; *4,6-dinitro-N-aryl-m-toluidines:* $PhNH_2$ 145°, *m*-$MeC_6H_4NH_2$ 150°, *m*-xylidine 186°, *p*-$MeOC_6H_4NH_2$ 139°. 2,3,5-Trinitro-*p*-xylene reacts with the replacement of the 2-NO_2 group; *3,5-dinitro-N-methyl-p-xylidine;* this reagent does not react readily with many aliphatic amines. The colors obtained by the addn. of H_2SO_4 or of H_2SO_4 and $PhCHCl_2$ to aromatic hydrocarbons were given when the latter were highly purified and these tests, together with the fluorescence in C_6H_6 soln., are valuable aids for detection and identification; colors are given for a large no. of hydrocarbons. Vanscheidt's reagent (*C. A.* **29**, 2160[3]) with *p*-$C_6H_4(NO_2)_2$ gives characteristic green or blue colors with cyclopentadiene in Me_2CO or C_5H_5N; the mere presence of a CH_2 group is insufficient to give the test. C. J. W.

Emulsin. XL. Glucoside of isethionic acid and its ethyl ester. B. Helferich and H. Lutzmann. *Ann.* **541**, 1–16(1939); cf. *C. A.* **34**, 782[3].—$HOCH_2CH_2SO_3H$ (26 g.) in 50 cc. H_2O, shaken with 28.5 g. Ag_2CO_3, gives 46.7 g. of the *Ag salt* (I); for purification 90 g. was rubbed with a little EtOH, dissolved in 1.25 l. EtOH and 50 cc. H_2O, clarified with C, cooled to 40° and treated with 0.5 l. Me_2CO and, after filtration, with an addnl. 3 l. Me_2CO, giving 78 g. I, m. 110° (all m. ps. cor.). Addn. of 10 g. I (rubbed under abs. C_6H_6) during 20 min. to 17.6 g. acetobromoglucose in 75 cc. abs. C_6H_6 at 50° gives an acid reaction to Congo in 10 min.; after cooling to room temp. 17.8 g. Ag_2CO_3 are added and the mixt. is shaken for 20 min. in the dark; addn. of 400 cc. abs. Et_2O ppts. the Ag salt of tetraacetyl-β-*d*-glucosidoisethionic acid; this is extd. with Me_2CO and treated with 2 moles of EtI, giving 58% of *Et tetraacetyl-β-d-glucosidoisethionate* (II), pptd. from 40 parts of Me_2CO or 2–3 parts abs. EtOH by 100 parts of H_2O, m. 125°, $[\alpha]_D^{19}$ −15.4° ($CHCl_3$); it is unstable and unexpectedly reduces hot Fehling soln. In Me_2CO an excess of aq. KOH at room temp. during 15 min. removes the Ac groups and saponifies the ester group. *Et β-d-glucosidoisethionate* (III), m. 89°, $[\alpha]_D^{19}$ −24.1° (H_2O); it is unstable and is decompd. slowly by H_2O in the cold and quickly on heating; the resulting soln. reduced Fehling soln. only after hydrolysis with AcOH. β-Glucosidoisethionic acid (IIIA) could not be isolated; the aq. soln. results from the ester after standing several weeks at room temp., during which the pH is reduced from 5.1 to 1.7 (29 days) and α from −0.25° to −0.66°; no free glucose is formed; IIIA results from the ester on heating on a water bath for 20 min.; Fehling soln. is not reduced until after acid hydrolysis; decompn. results on evapn. of the soln. The *Na salt* (IV) of IIIA is obtained by neutralization of IIIA and pptd. from MeOH by Me_2CO and Et_2O as an amorphous ppt. and which may be obtained cryst. by seeding. Hydrolysis of the tetra-Ac deriv. (*C. A.* **32**, 4953[7]) by titration with MeONa in $CHCl_3$ at −18°, neutralization with *N* H_2SO_4, washing the $CHCl_3$ layer with H_2O and neutralization with $NaHCO_3$, evapn. to dryness, extn. with MeOH and crystn. from 22 parts of AcOEt give 90% of *β-glucosidoethylene chlorohydrin* (IVA), m. 67–8°, $[\alpha]_D^{19}$ −29.2° (H_2O), which has a bitter-sweet taste and reduces Fehling soln. only after hydrolysis. *Tetraacetyl-β-d-glucosidoethylene bromohydrin* (V), m. 118°, $[\alpha]_D^{19}$ −12.3° ($CHCl_3$); *β-d-glucosidoethylene bromohydrin* (VI), m. 74–5°, $[\alpha]_D^{19}$ −26.1° (H_2O), 90% yield, bitter-sweet taste. The *iodohydrin* corresponding to V m. 100–1°, $[\alpha]_D^{19}$ −11.9° ($CHCl_3$), 90%; *iodohydrin* (VII) corresponding to VI, m. 120–1°, $[\alpha]_D^{19}$ −25.3° (H_2O), bitter taste. VII and 1 mole Na_2SO_3 in 60–70 cc. H_2O, heated 6 hrs. at 60°, give IV, with 1 mole H_2O, m. 130–1°, $[\alpha]_D^{19}$ −32.9° (H_2O). IV has a sweet taste which then becomes salty; the tetra-Ac deriv., which could not be crystd., was transformed into the free acid, which gives II with $MeCHN_2$ and with MeONa in $CHCl_3$-MeOH II gives III. III (0.6422 g.) with 39 cc. 0.01 *N* NaOH at 20° (α −0.70°) shows no rotation after 5 hrs.; the pH fell from 11.2 to 10 during this time and much quicker after this time; 50% of glucose was split off, after which the alkali was neutralized. With 0.5 *N* NaOH at 19° 100% of glucose is split off at 7 hrs. The activity and percentage of splitting with sweet almond emulsin are: IV 0.0009, 28%; III 0.32, 25%; IV 0.44, 25%; VI 0.58, 27%; VII 0.94, 28%.
C. J. West

Emulsin. XLII. The cleavability of *d*-xylosides, *l*-xylosides and *dl*-xylosides by sweet-almond emulsin. Burckhardt Helferich, Erich Günther and Wm. W. Pigman. *Ber.* **72B**, 1953–9(1939); cf. *C. A.* **34**, 782[4].—The question of the enzymic cleavability of glucosides of enantiomorphic sugars has seldom been studied because suitable materials (substrate as well as enzyme) are only rarely available. Sweet-almond emulsin (I) cleaves β-*d*-xylosides, even if but slowly (the designation *d*-xylose is used for the xylose, closely related configurationally to glucose, which occurs in nature), and the authors have undertaken a comparative study of the cleavability of β-*d*- and β-*l*-xylosides by I. Phenol β-*l*-xyloside (II), which can be synthesized just like the *d*-antipode (*C. A.* **27**, 2080), is cleaved only very slightly, if at all, by I, even in high concns. and after long-continued action. On bringing together satd. solns. of *d*- and *l*-II there rapidly seps., in good yield, the cryst. *dl-compd.*, m. 187° (cor.); in the aq. soln. of the racemate the presence of the *l*-form retards slightly the cleavage of the *d*-form by I.

This affords a new method, probably hitherto never before used, for the preparative resolution of *dl*-sugars into their active components. The 3-*β*-*d*- and -*l*-xylosides (III) of protocatechualdehyde 4-*β*-*d*-glucoside (IV) were also tested. The *d*-form, in which both sugar components belong to the *d*-series, was cleaved by I to about the same extent as other known diglucosides of the aldehyde, whereas in the *l*-form the *β*-*d*-glucosidic union was cleaved to a much smaller extent (about 0.01 as much). With a I of high activity, the glucose in *l*-III was completely split off; from the end rotation, $[\alpha]_D$ for protocatechualdehyde *β*-*l*-xyloside is calcd. to be 82°. Below are the values (*Wertigkeiten*) of the different glucosides toward I of glucosidase value 1.1: *d*-II, 0.0058; *l*-II, 0.000005; *dl*-II (calcd. for the *d*-form only), 0.0051; *d*-III, about 0.1; *l*-III, about 0.001. *Tetraacetyl-β-d-xylopyranose* (V) (173 g. from 150 g. *l*-xylose and 150 g. NaOAc in 900 cc. Ac_2O dissolved in about 10 min. by heating on the water bath and heated 2 hrs. longer), m. 123–5°, $[\alpha]_D^{20}$ 25.3° ($CHCl_3$). *Triacetylphenol-β-l-xylopyranoside* (8.4 g. from 20 g. V), m. 143–5°, $[\alpha]_D^{20}$ 50.7° ($CHCl_3$); *l*-II (5 g. from 10 g. of the tri-Ac compd.), m. 178–80°, reduces Fehling soln. on long boiling, $[\alpha]_D^{20}$ 49.5° (water). Acetobromo-*l*-xylose (8.3 g. from 10 g. tetraacetyl-*l*-xylose), m. 95–7°; 8.3 g. added to 15.2 g. of the tetra-Ac deriv. of IV and 1 g. NaOH in aq. acetone and allowed to stand 15 hrs. gave 4.9 g. of the *hepta-Ac deriv.* (VI), m. 148–50°, $[\alpha]_D^{20}$ 9.4° ($CHCl_3$), of *l*-III, which with NaOMe in boiling MeOH yielded 2.8 g. *l*-III, m. 235–7°, $[\alpha]_D^{20}$ −32.7° (water). *d-Form* of VI (5.2 g. from 10 g. acetobromo-*d*-xylose), crystals with 0.5 mol. EtOH, sinters about 72°, m. (alc.-free) 128–30°, $[\alpha]_D^{20}$ −89.8° (water). C. A. R.

Fructose anhydrides. XXII. Secalin. Hans H. Schlubach and Christa Bandmann. *Ann.* **540**, 285–97 (1939); cf. *C. A.* **32**, 5067.—Unripe rye (about 14 days after flowering) was extd. for 20 min. with boiling 96% EtOH and then for 20 min. with boiling 50% EtOH; the concd. ext. was freed from chlorophyll by basic Pb acetate at 60°, the Pb removed with H_2S, the soln. evapd. to a sirup and the carbohydrate pptd. from a little H_2O by EtOH and Et_2O; the yield of sirup is 3.2% with α_D −8° to −20.5°. Fractional pptn. from H_2O with EtOH gives after 100 pptns. a ppt. contg. 34% ash and with $[\alpha]_D$ −37.6°. Acetylation in 90% C_5H_5N gives 84.5% of crude Ac deriv.; reacetylation and 80 pptns. from boiling C_6H_6 with petr. ether give the *Ac deriv.* (I), $[\alpha]_D$ 3° ($CHCl_3$, *c* 1); 290 g. crude I gives 115 g. of pure I. Hydrolysis by MeONa in MeOH gives a pure *secalin* (II), $[\alpha]_D$ −37.5°; with 0.1 *N* H_2SO_4 II is 50% hydrolyzed in 226 min.; the reduction value (Bertrand) is 0; the rotation change on acid hydrolysis is from 37.9° to 86.3° during 2733 min. (75% hydrolysis). The mol. wt. is 667 (817 for N before acetylation). I in Me_2CO at 50° with Me_2SO_4 and 30% NaOH gives the *Me deriv.* (III), $[\alpha]_D$ −45° ($CHCl_3$, *c* 0.37), 45% MeO. Hydrolysis by boiling 20 g. III in 1050 cc. 96% EtOH with 15 g. $(CO_2H)_2$ in 188 cc. H_2O for 12 hrs. and reaction of the sirup with *β*-$C_{10}H_7COCl$ give 3.1 g. of the 1,3,4,6-tetramethylmethylfructoside, and 9.4 g. of trimethylnaphthoylmethylfructoside, $b_{0.1}$ 80°, m. 75°, n_D 1.4652, $[\alpha]_D$ −8.3° (MeOH, *c* 0.24) changing to −2.6°, 11.7° ($CHCl_3$, *c* 1) changing to 18.7°, which is probably the 1,3,4-tri-Me deriv. The distn. residue (6.7 g.) is a brown sirup, with $[\alpha]_D$ −7.6° ($CHCl_3$, *c* 0.79), −14.6° (MeOH, *c* 0.76) changing to −21.2°; this is probably the 1,3-di-Me deriv., identical with that from triticin (*C. A.* **32**, 6620[1]). The ratio of the 3 hydrolysis products is 1.2:1. II is therefore a tetrafructose anhydride and is quite different in its structure from graminin. C. J. West

Partially methylated disaccharides. II. Experiments on maltose. Kurt Hess and Wolfgang Gramberg. *Ber.* **72B**, 1898–905(1939); cf. *C. A.* **31**, 4959[8].—While there are numerous possible methods of selectively substituting the HO groups of monosaccharides, similar substitutions in disaccharides have been effected only in relatively few cases. In part I was described the prepn. of 2,3,6,8,9-pentamethyl-*β*-benzylmaltoside (I) and cellobioside wherein, in view of the known selective methylation of *α*- and *β*-Me glucosides at the 2- and 3-positions, condensation with BzH was selected to protect the 10- and 12-HO groups in the disaccharides. From the smooth further selective methylation, in Me glucosides, of the primary alc. group by the series of reactions tritylation (C6) → tosylation (C4) → detritylation → methylation (C6), I should be methylated at position 12 to give the 2,3,6,8,9,12-hexa-Me compd. (II), of importance for further syntheses. Actually, the reactions followed, in part, a different course. The prepn. of pure I was materially improved. Benzylidene-*β*-methylmaltoside was heated 24 hrs. at 40° in smaller portions (1 g. instead of 5 g.) with a larger excess of Ag_2O (30 g., added in 2 portions, instead of 21 g.) and 30 (instead of 55) cc. MeI, the product from several runs was worked up as before, and the product remaining in the mother liquors was repeatedly methylated under the same conditions until the yield of the benzylidene deriv., m. 140° (formerly given as 132–3°), of I was practically quant. The yield of I from the benzylidene deriv. was somewhat increased (to 66%) by boiling the latter with much more dil. HCl-MeOH (0.004 instead of 0.1 *N*). I m. 109.5–10.5° (previously given as 103–4°), $[\alpha]_D^{20}$ 35.3° (MeOH), 49.9° ($CHCl_3$), 10.2° (acetone). *10,12-Diacetate* (75% from I and Ac_2O pyridine at 20°), m. 85–6°, $[\alpha]_D^{20}$ 29.5° (MeOH), 40.9° ($CHCl_3$), 11.5° (benzene). *10,12-Dibenzoate* (90% from I and BzCl in pyridine at 115°), m. 146.5°, $[\alpha]_D^{20}$ 51.7° (benzene), 68.8° ($CHCl_3$), 48.5° (acetone). With Ph_3CCl in pyridine at 20°, I yielded 61% of the *12-trityl ether* (III) (completely sepd. from the accompanying Ph_3COH only by sublimation under 0.0001 mm., the Ph_3COH passing over at 60–120°, III at about 215°). The sublimate, whose cryst. character could be readily seen under the microscope, m. 70–80°, $[\alpha]_D^{20}$ 39.2° (MeOH), 35.3° ($CHCl_3$), 33.6° (benzene). It could not be cryst'd. from solvents; from the ordinary solvents it was obtained only as an oil or sirup and from hot hexane it sepd. on long standing in voluminous flocks which, after filtration, formed a loose, non-cryst. powder. On detritylation with 1.2 mols. HCl in AcOH it regenerated I. Toward tosyl chloride in pyridine, III behaved unlike the monosaccharides; even at 180° no esterification occurred. On the other hand it readily formed a *10-benzoate* (IV) (best prepd. directly after the tritylation in the same reaction mixt. with 1.5 mols. BzCl at 125°; yield, 24%), m. 70–80°, $[\alpha]_D^{20}$ 42.7° (MeOH), 52.3° ($CHCl_3$), 31.9° (benzene). With 1.1 mols. $PhCH_2COCl$ at 70° was similarly obtained a *phenylacetate*, sublimes at 220° under 0.0002 mm. With boiling *N*/7 NaOMe in MeOH IV regenerated I. When IV was allowed to stand 15 min. at 0° with 1.5 mols. HCl in AcOH, filtered from the Ph_3CCl, taken up in $CHCl_3$, shaken out repeatedly with water to convert the remaining Ph_3CCl into Ph_3COH, evapd., freed from the Ph_3COH by heating in a high vacuum at 130°, and the whole process was repeated 3 times more, there was finally obtained a product, consisting chiefly of a monobenzoate of I, which, however, on methylation with Ag_2O and boiling MeI gave, instead of the desired 2,3,6,8,9,12-hexamethyl-10-benzoyl-*β*-benzylmaltoside, the isomeric *2,3,6,8,9,10-hexamethyl-12-benzoyl compd.* (V), viscous oil, $[\alpha]_D^{20}$ 31.8° (MeOH), 39.5° ($CHCl_3$), 22.2° (benzene), for on debenzoylation with *N*/7 MeONa-MeOH and cautious hydrolysis of the resulting hexa-Me ether with 5% HCl on the water bath it gave 2,3,6-trimethyl-*β*-benzylglucoside and the non-cryst'g. 2,3,4-trimethylglucose, $[\alpha]_D^{20}$ 59.7° (MeOH), 62.4° (water). Hence a migration of the Bz group had occurred, very probably during the detritylation with acid. For preparative purposes V can be made directly (420 mg. yield) from 1500 mg. I heated 2 hrs. at 100° with 990 mg. Ph_3CCl and 5 cc. pyridine, then 2 hrs. at 120° with 0.5 cc. BzCl, freed from the pyridine by distn., treated 15 min. at 0° with 1.3 mols. HCl in 5 cc. AcOH, dild. with much $CHCl_3$, shaken with $NaHCO_3$, washed with water, evapd., freed from the Ph_3COH by sublimation (bath temp. up to 160°) in a high vacuum, and taken up in 5 cc. EtOH, whereupon the 10,12-dibenzoate (450 mg.) soon seps. completely. The residue from the alc. mother liquors is subjected anew to the HCl-AcOH treatment and the

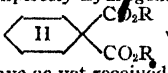
subsequent operations, and the residue (1050 mg.) remaining after the sublimation of the Ph_3COH is then boiled 15 hrs. with 25 g. MeI and 5 g. Ag_2O added in 2 portions. **III. Experiments on cellobiose.** Kurt Hess and Hsin-Lu Hwang. *Ibid.* 1906–8.—Pentamethyl-β-benzylcellobioside (I) behaves like the maltose analog (part II above). Its *12-trityl ether* (70% from I with Ph_3CCl in pyridine at room temp.), sublimes at 170–220° under 0.0004 mm., $[\alpha]_D^{20}$ −17.74° (acetone), −36.21° (benzene), −25.99° (CHCl₃), −16.74° (MeOH), cannot be tosylated. It yields, however, with BzCl in pyridine at 100° 64.3% of the *10-benzoate*, sublimes at 190–220° under 0.005 mm., $[\alpha]_D^{20}$ −18.3° (acetone), −19.9° (benzene), −13.2° (CHCl₃), −17.4° (MeOH), which is converted by 1.5 mols. of 5.5% HCl in AcOH at 10° into *2,3,6,8,9-pentamethyl-12-benzoyl-β-benzylcellobioside*, $[\alpha]_D^{20}$ −28.9° (acetone), −41.1° (benzene), −35.2° (CHCl₃), −32.4° (MeOH); this with Ag_2O and MeI at 60° yields the sirupy *2,3,6,8,9,-10-hexa-Me compd.*, $[\alpha]_D^{20}$ −39° (acetone), −42° (benzene), −30.2° (CHCl₃), −33.8° (MeOH), which on cautious hydrolysis gives 2,3,6-trimethylbenzylglucoside and 2,3,4-trimethylglucose. *10,12-Dibenzoate* of I (85% from I and 2.5 mols. BzCl in pyridine at 115°), sirup, $[\alpha]_D^{20}$ −27.7° (acetone), −47.7° (benzene), −31.5° (CHCl₃), −34.2° (MeOH). C. A. R.

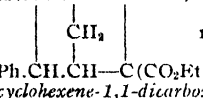
Polysaccharides. XXXII. The molecular constitution of rice starch. E. L. Hirst and G. T. Young. *J. Chem. Soc.* **1939**, 1471–82; cf. *C. A.* **33**, 6807⁴.—Rice starch (I), in common with all other starches hitherto examd., contains a repeating unit composed of a straight chain of 24–30 glucose residues. Independently of the mode of prepn. of the Me deriv. whether the starch grain is methylated directly in air or N or whether the Me deriv. is prepd. via the acetate—and irrespective of the mol. wt. of the methylated starch, the percentage of end group (tetramethylglucose) obtained on hydrolysis remains unchanged. The observed proportion of end group cannot therefore be explained by random hydrolysis of long main chains of similarly united residues and it is concluded that viscous methyl starches are composed of a large no. of repeating units joined together laterally, forming side chains. In support of this view, a viscous methyl starch contg. some 80 repeating units (mol. wt. approx. 500,000) has been disaggregated by controlled hydrolysis into a non-viscous, essentially homogeneous Me deriv., which, on further methylation to etherify the HO groups liberated during the disaggregation process, gives the fully methylated deriv. Osmotic pressure and ultracentrifuge measurements show that the latter has a mol. wt. corresponding to about 3 repeating units (90 glucose residues) and on hydrolysis the methylated disaggregated deriv. gives precisely the same amt. of tetramethylglucose as do the viscous derivs. but the yield of dimethylglucose is now very small. Consideration of the conditions of the disaggregation process leads to the conclusion that in the starch mol., the repeating units, each consisting of a chain of 30 glucose residues, are linked to a non-terminal glucose residue of another unit by primary valencies of the glucosidic type. The relationship between viscosity data and mol. wt. in the methyl starch series is considered and an empirical method is suggested for the utilization of viscosity results in the detn. of approx. mol. sizes. The I used had [illegible] 152° (*N* NaOH, *c* 0.4). Acetylation of I in AcOH contg. a little Cl with Ac_2O-SO_2 gives 85% of an *acetate* (II), $[\alpha]_D^{20}$ 174°, η^{20} 0.494 in *m*-cresol (*c* 0.4), corresponding to an apparent mol. wt. of 380,000; Ac_2O in C_5H_5N at 70° gives 92% of an *acetate* (III), $[\alpha]_D^{20}$ 171° (CHCl₃, *c* 0.55%), η^{20} 0.93 in *m*-cresol (*c* 0.4) and an apparent mol. wt. of 720,000. I was methylated under various conditions. Pptd. I with Me_2SO_4 and 30% NaOH at 20° in air gives 60–70% of a Me deriv., fractionally pptd. from $CHCl_3$ by petr. ether into 3 fractions (8, 12 and 7.4 g.) showing apparent mol. wts. of 520,000, 385,000 and 250,000. "Prepared" I with Me_2SO_4 and 30% NaOH in air at 55° (finally at 100° for 30 min.) gives a Me deriv., sepd. into 4 fractions (3.7, 5.9, 4.1 and 5.7 g.) with apparent mol. wts. of 190,000, 250,000, 205,000 and 95,000. Methylation in a N atm. at 20° gives 75% of a product with 45.4% MeO (8 treatments); this Me deriv. was sepd. into 4 fractions (0.6, 34, 8.2 and 3.5 g.) with apparent mol. wts. of 560,000, 525,000, 400,000 and 175,000. Deacetylation and methylation of II give a Me deriv. (44% MeO), sepd. into 2 fractions (4.5 and 7.9 g.) with apparent mol. wts. of 600,000 and 510,000; III gives 89% of a Me deriv. with an apparent mol. wt. of 670,000. All these derivs. showed $[\alpha]_D^{20}$ from 205° to 212° (CHCl₃). Hydrolysis of the Me derivs. gives values of 2,3,4,6-tetramethylglucose corresponding to 29–34 glucose residues for the repeating unit or mol. wts. from 5900 to 6900. On heating in *m*-cresol (0.4% concn.) at 150° the apparent mol. wt. changes from 205,000 to 13,000 in 29 hrs.; on boiling in a soln. of 1 g. of $(CO_2H)_2$ in 75 cc. MeOH and 25 cc. H_2O (concn. 2.5%) the change is from 520,000 to 23,000 in 142 hrs.; $[\alpha]_D^{20}$ varied only from 211 to 207°. An examn. of the methylated disaggregated starch in the ultracentrifuge is reported by J. St. L. Philpot and E. Dodwell. C. J. West

Constitution of the mucilage from the bark of Ulmus fulva (slippery elm mucilage). I. The aldobionic acid obtained by hydrolysis of the mucilage. R. E. Gill, E. L. Hirst and J. K. N. Jones. *J. Chem. Soc.* **1939**, 1469–71.—Extn. of slippery elm bark with hot H_2O for 24 hrs. and the filtered soln. poured into 3 vols. of MeOH acidified with HCl gives the polysaccharide (I), $[\alpha]_D^{20}$ 12° (H_2O, *c* 1); the very viscous aq. soln. of I is acid in reaction. Boiling an aq. soln. of I causes partial hydrolysis with the sepn. of about 10% of dark material which contains C, H, N and S. The filtrate on pouring into EtOH gives a polysaccharide (II) with $[\alpha]_D^{20}$ 68° (H_2O, *c* 1), equiv. wt. by titration 468, uronic anhydride 36.6%, furfural and methylfurfural 18% (the latter approx. 12%). Hydrolysis of 20 g. of II with *N* H_2SO_4 at 90° for 9 hrs. and the pptd. Ba salt purified by pptn. from H_2O by EtOH gives 14 g. of the *Ba salt*, $(C_{12}H_{19}O_{11})_2Ba$; removal of the Ba as $BaSO_4$ and evapn. of the soln. at 40°/12 mm. (addn. of *N* TlOH), followed by boiling with MeI give a sirup which, on further methylation with Purdie reagents, removal of methylated monosaccharides by distn. at 120°/0.01 mm. and remethylation 3 times, gives the *Me ester* of *2-(2,3,4-trimethyl-d-galacturonido)-3,4-dimethylmethyl-l-rhamnopyranoside* (III), $b_{0.01}$ 170° (bath temp.), n_D^{19} 1.4722, $[\alpha]_D$ 76° (H_2O, *c* 3.2). Hydrolysis of 0.79 g. III with 2 *N* HCl at 95°, removal of the HCl with Ag, of the Ag with H_2S and neutralization with $BaCO_3$ gives a product, from which Et_2O gives 0.20 g. of a sirup, 3,4-dimethylrhamnose, n_D^{19} 1.4730, $[\alpha]_D^{19}$ 20° (H_2O, *c* 2), which is oxidized by Br to 3,4-dimethyl-*l*-rhamnonolactone. Oxidation of the residual Ba salt with Br and boiling with 3% MeOH-HCl give Me 2,3,4-trimethyl-*d*-galacturonic acid. Thus the aldobionic acid is *2-d-galacturonido-l-rhamnose* and is identical with an aldobionic acid isolated from flax seed mucilage by Tipson, Christman and Levene (*C. A.* **33**, 7278⁸). C. J. West

Constitution of damson gum. II. Hydrolysis products from methylated degraded (arabinose-free) damson gum. E. L. Hirst and J. K. N. Jones. *J. Chem. Soc.* **1939**, 1482–90; cf. *C. A.* **32**, 8374⁸.—It was shown previously that graded hydrolysis of damson gum gave a polysaccharide (I) which contained 1 part of *d*-glycuronic acid, 1 of *d*-mannose, approx. 3 of *d*-galactose and about 3% of *d*-xylose. I (40 g.) has now been methylated with MeI and TlOH, giving 38 g. of the Me deriv. (II) (38.9% MeO). Fractionation by addn. of petr. ether to a $CHCl_3$ soln. failed to give portions differing essentially from 1 another. Hydrolysis of 9.55 g. of II with 100 cc. *N* HCl contg. 20 cc. AcOH for 6 hrs., removal of the Cl with Ag_2CO_3, neutralization of the soln. with $BaCO_3$ and extn. with C_6H_6, followed by methylation, give 3.2 g. of Me glucosides; the aq. soln. on concn., extn. with Me_2CO, esterification and hydrolysis with $Ba(OH)_2$ yields an addnl. 4.05 g. of glucosides; the Ba salts give 2.78 g. of glucuronic acids. The glucosides were sepd. into 7 fractions, from which were isolated 2,3,4-trimethyl-*d*-xylose (0.25 g.), identified as such and as the corresponding lactone; 2,3,4,6-tetramethyl-*d*-galactose (1.15 g., 1 part), identified as the anilide, m. 197°: 2,3,4-trimethyl-*d*-galactose (III) (1.43 g., 1 part) and the 2,4,6-isomer (IV) (1.26 g., 1 part), identified as the anilides (*that* of IV m. 179°, $[\alpha]_D^{19}$ −92°

(Me_2CO, *c* 1.1), changing to 38° in 22 hrs.; a partial sepn. of III and IV can be effected by fractional distn. of the mixed Me galactosides, that of IV being obtained cryst.); 4,6-dimethyl-α-*d*-galactose (V) (1.29 g., 1 part), which was sepd. as *4,6-dimethyl-α-β-methyl-d-galactoside*, m. 163°. V seps. from Me_2CO as the hydrate, m. 105°, $[\alpha]_D^{25}$ 123° (H_2O, *c* 3.7), which falls to 82°. The *anilide* of V m. 207°, $[\alpha]_D^{25}$ −174° (C_5H_5N, *c* 0.35). There is no downward change in the rotation of V with cold 1% MeOH-HCl, indicating the absence of a HO group on C_4; oxidation with Br-H_2O for 24 hrs. gives *4,6-dimethyl-d-galactonolactone*, $[\alpha]_D^{25}$ 78° (MeOH, *c* 2.4), 91° (H_2O, *c* 1.2), changing to 45° in 60 hrs.; liquid NH_3 yields *4,6-dimethyl-d-galactonamide hydrate*, m. 164°, $[\alpha]_D^{25}$ 54° (H_2O, *c* 2), which gives a pos. Weerman reaction with NaOCl, indicating a free HO group at C_2. 2,3-Dimethyl- and 2,3,4-trimethyl-*d*-glucuronic acids (1 part each) were isolated from the acid fraction. Full details are given of the various methods used for the identification of each of the above products. All the sugars must be present in I as pyranose residues. It has not been possible to identify the mannose residue which is present partly among the distd. Me glycosides and partly as incompletely hydrolyzed material in the undistillable residue of the uronic acid portion. The meaning of these results in connection with the mode of linkage of the sugar residues present in the damson gum mole is briefly discussed. C. J. West





Isomerization of polymethylene hydrocarbons under the influence of aluminum chloride. III. Isomerization of ethylcyclopentane and of methylcyclohexane. M. B. Turova-Pollak and Z. Makaeva. *J. Gen. Chem.* (U. S. S. R.) **9**, 1279–82(1939); cf. *C. A.* **33**, 9293¹.—When 50 g. ethylcyclopentane (I), b_{760} 103.0–3.2°, d_4^{20} 0.7672, n_D 1.4198, is heated with 23 g. $AlCl_3$ at 110–115° for 20 hrs. an equil. mixt. contg. 97% methylcyclohexane (II) and 3% I is formed. II, b_{760} 99–100°, d_4^{20} 0.7687, n_D^{20} 1.4240, with $AlCl_3$ under the same conditions gives a mixt. contg. 6.3% I and 93.7% II. John Livak

Tetrahydrocitrylidene- and citronellylideneacetic acids. Syntheses of *sec*-isoöctylcyclopentane derivatives. H. N. Rydon. *J. Chem. Soc.* **1939**, 1544–9.—This work had as its object the synthesis of 2-methyl-3-*sec*-isoöctylcyclopentanone, the necessary starting material for the synthesis of cholesterol by the Mannich base method (*C. A.* **31**, 2202⁷; **32**, 7444⁸). Tetrahydrocitral (I) (41 g.), 39 g. $(HOCH_2CH_2)_3N$ and 28 g. $CH_2(CO_2H)_2$ (II), heated on the water bath for 21 hrs., acidified with 50% H_2SO_4 and extd. with Et_2O, give 15 g. (29%) of *tetrahydrocitrylideneacetic acid* (III), b_{15} 164–6°, n_D^{18} 1.4459, which contains 66% of the Δ³-isomer. II (285 g.), added to 250 g. I and 500 cc. C_5H_5N, kept at room temp. for 6 hrs. and heated on the water bath overnight, gives 75% III contg. 25% of the Δ³-isomer. III (1 g.-mole) with 100 cc. *N* EtOH-HCl and 230 cc. abs. EtOH, kept at room temp. overnight and poured into excess 10% Na_2CO_3, gives *Et 5,9-dimethyl-3-decenoate* (IV), b_{15} 134–5°; acidification of the residual Na_2CO_3 soln. gives *5,9-dimethyl-2-decenoic acid* (V), b_7 158–60°, n_D^{18} 1.4580 (*p-bromophenacyl ester*, m. 47°). Hydrolysis of IV gives *5,9-dimethyl-3-decenoic acid* (VI), b_{13} 162°, n_D^{18} 1.4540 (*p-bromophenacyl ester*, m. 39°). V (118 g.) with 50 g. NaOH in 100 cc. EtOH and 100 cc. H_2O, heated on a water bath for 24 hrs., is converted into VI; the equilibrated acid contains 53% of V. VI with $KMnO_4$ gives 2,6-dimethylheptanoic acid; mixing 92 g. VI with 92 g. concd. H_2SO_4, with cooling, gives 57% of *γ-sec-isoöctyl-γ-butyrolactone* (VII), b_{13} 158–62°, n_D^{18} 1.4619. With HBr at 0° VII gives 65% *Et 4(?)-bromo-5,9-dimethyldecanoate* (VIII), $b_{1.5}$ 145–50°. VI (52 g.) and HBr at room temp. with 50% HBr-AcOH yields 30 g. VIII. VIII gave no useful condensation product with $NCCHNaCO_2Et$. Citronellylideneacetic acid on partial esterification gives 28% of the *Et ester*, b_{13} 139–41°, of *5,9-dimethyl-3,8-decadienoate* (IX), b_1 163–8°, and the residual Na_2CO_3 soln. gives 60% of the Δ²,⁸-isomer, b_{13} 173–5°. The equil. acids contain 75% of IX. The K deriv. of Et cyclopentanone-2-carboxylic acid and *sec*-isoöctyl iodide (X) in xylene, refluxed 33 hrs. at 140–50°, give 59% of *Et 2-sec-isoöctylcyclopentanone-2-carboxylate*, b_{14} 165–75°, n_D^{18} 1.4588; refluxing with aq. $Ba(OH)_2$ for 72 hrs. gives 13% of XI and also *α-sec-isoöctyladipic acid* (XI), m. 54°; distn. of XI with $Ba(OH)_2$ at 350–60° gives 52% of *2-sec-isoöctylcyclopentanone* (XII), b_{17} 135–7°, n_D^{18} 1.4548 (*2,4-dinitrophenylhydrazone*, yellow, m. 86–7°). XII reacts with MeMgI to yield 60% of *1-methyl-2-sec-isooctyl-1(2)-cyclopentene*, b_{18} 112–15°, n_D^{18} 1.4572; this reacts with SeO_2 in BuOH to give a complex mixt. which has not been investigated fully. The Grignard reagent from X does not react with cyclopentanone. Cyclopentyl bromide and $AcCHNaCO_2Et$ in EtOH, refluxed 4 days, give 63% of *Et cyclopentylacetoacetate* (XIII), b_{18} 125–30°, n_D^{18} 1.4527; $PhNHNH_2$ gives *1-phenyl-3-methyl-4-cyclopentyl-5-pyrazolone*, pale yellow, m. 133–4°. XIII, MeI and MeONa give 66% of *Et cyclopentylmethylacetoacetate*, b_{13} 128–31°, n_D^{18} 1.4607°; refluxing with aq. KOH for 18 hrs. gives 69% of *α-methyl-α-cyclopentylacetone* (XIV), b_{17} 76–9°, n_D^{20} 1.4470; *semicarbazone*, m. 98°. The condensation product of XIV and iso-PrCHO is a complex mixt. C. J. West

Anionotropic and prototropic changes in cyclic systems. VII. The structure of the chlorodiphenylcyclopentenone obtained by the action of hydrogen chloride on anhydroacetonebenzil. Harold Burton and Charles W. Shoppee. *J. Chem. Soc.* **1939**, 1408–15; cf. *C. A.* **33**, 5368⁴.—In part III (*C. A.* **28**, 2685⁶) it was suggested that the chloride, m. 129°, obtained from CPh CH CO.CH_2.CPhOH (Japp and Burton, *J. Chem. Soc.* **51**, 428(1887)) and Et-OH-HCl had the structure PhC:CCl.CO.CH_2.CHPh (I); Allen and Spanagel (*C. A.* **27**, 80) assigned the structure PhCH.CHCl.CO.CH:CPh (II) to this chloride and I to the product (III), m. 142°, from the reaction of $POCl_3$ and PhC:C(OH).CO.CH.CHPh (IV). B. and S. believe that III is PhCH.CO.CCl:CH.CHPh (V) and that it is obtained from the isomer of IV, i. e., PhCH.CO.C(OH) CH.CHPh (VI). IV (5 g.) and $POCl_3$ at 110° for 10 min. give 2.2 g. of V, m. 140°; this also results from 2,3-diphenylcyclopentenone (VII) and SO_2Cl_2 in C_6H_6; 2,4-dinitrophenylhydrazone, m. 215° and depressed the m. p. of I to 200°. V dissolves in piperidine (VIII) at 40° with immediate pptn. of VIII.HCl. V is not affected by Ag_2CO_3 or $BaCO_3$ in boiling MeOH but Na_2CO_3 (refluxing 0.5 hr.) gives the mono-MeO dimer (mol. wt. 1000). V does not yield an oxime, the product being a Cl-free *oxime*, $C_{31}H_{26}O_2N_2$, pale buff, m. 258–9° (decompn.). When treated with MeOH-HCl in piperonal at 0° for 24 hrs. or with glacial AcOH-HCl, V gives a compd. m. 188–9°, decomps. 210–15°. Reduction of V with HI and P (refluxing 2 hrs.) gives VII, isolated as the oxime. Catalytic reduction of V in EtOH-AcONa gives *trans*-2,3-diphenylcyclopentanone. I yields an *oxime*, m. 172°; *piperonylidene deriv.* of I, bright yellow, m. 165°. I does not react with NOCl in C_6H_6 in 48 hrs. Reduction of I with HI and P gives 3,4-diphenyl-Δ³-cyclopentenone (IX); catalytic reduction with PtO_2 in EtOH gives *cis-3,4-dicyclohexylcyclopentanol*, m. 91°; in EtOH-AcONa there results *cis*-3,4-diphenylcyclopentanone. Oxidation of V with O_3 gives only BzOH, although Allen and Rudoff (*C. A.* **32**, 1244) claim to have isolated desylacetic acid; $KMnO_4$ in 90% Me_2CO at −15° and CrO_3 in 90% AcOH at 43° also give only BzOH. Reduction of the oxime of I with PtO_2 in AcOH gives *trans-3,4-diphenylcyclopentylamine* (X), m. 119–20°; it absorbs CO_2 rapidly from the air; *picrate*, yellow, m. 232° (decompn.); *Ac deriv.* (XI), m. 119°. The oxime of *trans*-3,4-diphenylcyclopentanone on reduction with Na and EtOH gives X. The *cis*-ketoxime on reduction and acetylation gives the *cis-isomer* of XI, m. 133–4° (less sol.) and 128°. IX forms an *oxime*, m. 179°; reduction gives X. Reduction of *trans*-2,3-diphenylcyclopentanone oxime and acetylation give isomeric *1-acetamino-2,3-diphenylcyclopentanes*, m. 187° (less sol. in C_6H_6) and 170–1°. The oxime of VII gives the same isomers. γ,δ-Diphenyl-Δ^α-pentenoic acid

yields an *anilide*, m. 129–30°; reduction gives γ,δ-diphenylvaleric acid, whose *anilide* m. 111–12°; *Me ester*, b_{18} 206–8°; the ester with Na in C_6H_6 gives semisolid materials, which yield a semicarbazone(?), m. 237° (decompn.). C. J. West

Mobility of the saturated six- and seven-ring and the configuration of the 1,2-cycloheptanediols. J. Böeseken. *Proc. Acad. Sci. Amsterdam* **42**, 573–80(1939); cf. *C. A.* **33**, 8578[7]. C. R. Addinall

The diene synthesis. XIV. Preparation of alicyclic malonic, cyanoacetic and acetoacetic esters. Kurt Alder and Hans F. Rickert. *Ber.* **72B**, 1983–92(1939); cf. *C. A.* **33**, 1299[1].—Partially and completely hydrogenated alicyclic malonic esters of the type  with 2 CO groups on the same C atom have as yet received but scant study, and A. and R. therefore sought a simple method of prepg. them by the diene synthesis. As the olefin components for such syntheses were considered the methylenemalonic esters and their homologs and derivs., $RR'C:C(CO_2R)_2$, which are readily obtained by condensation of aldehydes and ketones with $CH_2(CO_2R)_2$. The simplest of these, $CH_2:C(CO_2Et)_2$, has such a great tendency to polymerize, however, that the more stable MeCH:$C(CO_2Et)_2$ (I) was selected. At elevated temps. it adds surprisingly smoothly, and for the most part with excellent yields, the most varied dienes. That the reactions are true diene syntheses (formation of 6-membered ring compds.) can be shown in various ways. Thus, the adduct with butadiene (II) smoothly adds 1 mol. H on catalytic hydrogenation and the product, b_{11} 131–3°, is hydrolyzed to 2-methylcyclohexane-1,1-dicarboxylic acid, m. 155–6°. Again, the adduct with cyclopentadiene (III) adds PhN_3 with the greatest ease to form the *hydrotriazole*  m. 158–9°. The following *di-Et* *3-cyclohexene-1,1-dicarboxylates* obtained in this way are described: *6-Me* (39 g. from 56 g. I and 50 g. II heated 14 hrs. at 170–80° in an autoclave), b_{11} 125–35°; *3,4,6-tri-Me* (230 g. from 200 g. I and 95 g. $(CMe:CH_2)_2$ (IV)), b_{11} 147–9°; *2,5-endomethylene-6-methyl* (210 g. from 220 g. I and 78 g. III), b_{11} 138–9°; *3,4-dimethyl-6-phenyl*, from 38 g. $PhCH:C(CO_2Et)_2$ and 14 g. IV, $b_{0.1}$ 156–8°, m. 52° (free *acid*, m. 190°, is decarboxylated at 210° to a mixt. of *trans*-3,4-dimethyl-6-phenyl-Δ^3-tetrahydrobenzoic acid, m. 157–8°, and the *cis-isomer*, m. 151°); *3,4-dimethyl-6-isopropyl*, b_{11} 155–7°, from 100 g. IV and 150 g. *di-Et isobutylidenemalonate*, b_{12} 115–16°, which is obtained in 90-g. yield from 54 g. iso-PrCHO. 120 g. $CH_2(CO_2Et)_2$ and 120 g. Ac_2O heated 24 hrs. at 125–30°; *3,4-dimethyl-6-ethyl* (from $EtCH:C(CO_2Et)_2$ and IV), b_{11} 149–50°; *6-methyl-2,5-endoethylene*, from 1,3-cyclohexadiene and I, b_{16} 155–6°. α,β-Unsatd. derivs. of $NCCH_2CO_2Et$, $CH_2(CN)_2$ and especially $AcCH_2CO_2Et$ proved to be equally well adapted to these diene syntheses. Thus, 29 g. MeCH:C(CN)CO_2Et and 24 g. IV gave 32 g. *Et 3,4,6-trimethyl-1-cyano-3-cyclohexene-1-carboxylate*, b_{11} 146–9°. *3,4-Dimethyl-6-phenyl-1,1-dicyano-3-cyclohexene* (42 g. from 30 g. $PhCH:C(CN)_2$ and 18 g. IV), b_2 155–6°, m. 81–2°. *Et 6-methyl-1-acetyl-3-cyclohexene-1-carboxylate* (70 g. from 60 g. MeCH:$CAcCO_2Et$ (V) and 70 cc. II), b_{11} 126–8°, hydrogenated to the cyclohexane ester, b_{11} 127–9°; *3,4,6-tri-Me homolog* (76 g. from 60 g. V and 40 g. IV), b_{12} 139–41°; *3,4-dimethyl-4-ethoxy analog* (55 g. from 62 g. EtOCH:$CAcCO_2Et$ and 40 g. IV), b_{12} 153–5°, slowly solidifies on standing to a cryst. mass. Even the completely substituted olefin $(EtO_2C)_2C:C(CO_2Et)_2$ (VI) adds dienes to form 6-membered rings. Heated 6 hrs. at 170–80° with 20 g. IV, 57 g. VI gave 65 g. *tetra-Et 4,5-dimethyl-4-cyclohexene-1,1,2,2-tetracarboxylate*, $b_{0.1}$ 151–3°. *Tetra-Et 4-cyclohexene-1,1,2,2-tetracarboxylate* (35 g. from 40 g. VI and 40 cc. II heated 8 hrs. at 170–80°), $b_{0.1}$ 149–51°, is smoothly hydrogenated to the *cyclohexane ester*, b_{11} 190–2°, which on hydrolysis loses 2 mols. CO_2, giving with alkalies *cis*-hexahydro-*o*-phthalic acid, m. 190–1°, and with acids the trans isomer, m. 222°. C. A. R.

Catalytic oxidation of cycloheptylamine. V. S. Smirnov. *J. Gen. Chem.* (U. S. S. R.) **9**, 1283–5(1939); cf. *C. A.* **33**, 4966[2].—The work on the catalytic oxidation of alicyclic amines was continued and 10% cycloheptylamine (I) in water was oxidized in the presence of Naturkupfer C in an O current, forming 36–64% suberone (II), whose semicarbazone m. 163°, hydrazone m. 48–9°, and dibenzal deriv., yellow, m. 106°. I, b. 165–9°, was prepd. in 22% yield from the oxime of II by reduction with metallic Na in alc. (cf. Markovnikov, *J. Russ. Phys. Chem. Soc.* **25**, 365(1893)). John Livak

Mechanism of the aromatization (of hydrocarbon oils). II. Thermal isomerization of the xylenes. A. F. Dobryanskiĭ and F. Ya. Saprykin. *J. Gen. Chem.* (U. S. S. R.) **9**, 1313–14(1939); cf. *C. A.* **33**, 4968[2].—The pyrolysis of pure *o*-xylene (I), *m*-xylene (II) and *p*-xylene (III) at 700°, 730°, 750° and 770° gave in all cases a xylene fraction, PhMe, condensation products which were not investigated further, and a gas fraction. At all of the temps. investigated II proved to be most stable and I least stable. Oxidation of the xylene fractions to the corresponding phthalic acids revealed that during pyrolysis I underwent partial isomerization to II and some III, III underwent slight isomerization to II, while II remained unchanged, again indicating its greater stability. J. L.

Method of preparation and physical data of monoalkylbenzenes. Albert W. Schmidt, Gerhard Hopp and Viktor Schoeller. *Ber.* **72B**, 1893–7(1939).—In the present paper are given the method of prepn. and phys. data of the monoalkylbenzenes used in the work on the chem. constitution and viscosity of benzene hydrocarbons with long side chains reported in *C. A.* **33**, 7747[8]. The values obtained for the phys. consts. differ more or less widely from those given in the literature. The *n* and d. values plotted against the no. of C atoms in the side chain fall on a curve while the points corresponding to the literature values are quite scattered. In the prepn. of the hydrocarbons by the Friedel-Crafts method, acid chlorides, which yield the easily purified ketones as primary products, were chosen rather than alkyl chlorides. Reduction of the ketones is the most difficult part of the prepn. The Clemmensen method gave unsatisfactory results; there were formed unsatd. compds. and oils, probably styrenes and their condensation products. Slight impurities in the Zn and HCl seemed to play a part in this. The Kishner-Wolff method, however, proved satisfactory. The ketones were heated with NaOEt and $N_2H_4.H_2O$ in autoclaves 12 hrs. at 180° and the resulting hydrocarbons, after distn., were treated a long time with Na, filtered through fullers' earth and carefully purified by repeated distn. In many cases it was found preferable to add the $N_2H_4.H_2O$ to the ketone first and then heat the resulting hydrazone with NaOEt. Below are given, resp., the b. p. (pressure in parentheses), n_D^{20}, d_4^{20} and the viscosity (centistokes) at 10° and 70° (the original gives the viscosities at 10, 20, 30, 40, 50, 60, 70 and 80°), of the *alkylbenzenes:* Et, — 1.4951, 0.8681, 0.863, 0.472; Pr, 47–9° (11 mm.), 1.4922, 0.8617, 1.140, 0.629 (at 60°); Bu, 66–8° (12 mm.), 1.4899, 0.8613, 1.395, 0.666; Am, 87° (12 mm.), 1.4887, 0.8600, 1.85, 0.811; hexyl, 97.5–101° (12 mm.), 1.4868, 0.8592, 2.31, 0.955; heptyl, 116–18° (12 mm.), 1.4860, 0.8590, 2.968, 1.126; octyl, 131–4° (12 mm.), 1.4851, 0.8582, 3.72, 1.316; dodecyl, 183–5° (12 mm.), 1.4822, 0.8564, 8.507, 2.287; tetradecyl, 153° (0.5 mm.), 1.4813, 0.8559, 12.33, 2.97; hexadecyl, 171° (0.1 mm.), 1.4814, 0.8558, 8.98 (at 30°), 3.71. C. A. R.

Alkylation and the action of aluminum halides on alkylbenzenes. Dorothy V. Nightingale. *Chem. Rev.* **25**, 329–76(1939).—The following generalizations may be made relative to the mechanism of alkylations by means of $AlCl_3$: (1) $AlCl_3$ probably forms a nonconducting, unstable complex with the reacting aromatic hydrocarbon. (2) With the alkyl halide $AlCl_3$ forms a complex, not isolated, of the type $R:X:AlCl_3$. This complex can ionize, yielding a pos. carbonium ion (R^+) and $(X:AlCl_3)^-$,

(3) Alkylation may then proceed in 2 ways: (*a*) the R^+ may coördinate with a pair of electrons from a double bond in the benzene ring, followed by the loss of a proton (Price, *C. A.* **33**, 5654) or (*b*) the compd. R:X:$AlCl_3$ may form a ternary complex with the reacting aromatic hydrocarbon, in which alkylation takes place with the loss of HX (Wertyporoch, *et al.*, *C. A.* **27**, 887, 2139; **28**, 10267). (4) The formation of a 1,3,5-hydrocarbon from a 1,2,4-hydrocarbon is explainable on the basis of Price's theory. According to this view, the alkyl radicals in the 2- and 4-positions direct the entering H to the 1-position, replacing the dissocd. alkyl radical. The carbonium ion may then either (*a*) re-alkylate the benzene ring from which it came to form a 1,3,5-hydrocarbon, or (*b*) alkylate another mol. of the 1,2,4- or a 1,3,5-hydrocarbon or (*c*) be hydrogenated to form an aliphatic hydrocarbon. There are much conflicting data in the literature and no one theory seems adequate to explain these data. L. K.

Isomerization of the β-substituted oxides of styrene. Influence of the saturated or unsaturated character of the substituent radical. Marc Tiffeneau and P. K Kuriaki. *Compt. rend.* **209**, 465–8(1939).— Expts. were carried out to show that the state of satn. of the substituent radical dets. the following reactions brought about by Mg etherates: PhCH.O.CHC·CH.CH_2.CH_2.CH_2.CH_2 by hydrobenzoin rearrangement to give CHOCHPhC CH.CH_2.CH_2.CH_2.CH_2; and PhCH.O.CHCH.CH_2.CH_2.CH_2.CH_2.CH_2 without rearrangement to give $PhCH_2CO$-CH.CH_2.CH_2.CH_2.CH_2.CH *sym* - Phenylcyclohexenylethylene (I) was converted into the epoxide (II) as follows. Phenacetyl chloride acting on I in the presence of $SnCl_4$ gave phenacetylhexene (III), m. 54°, b_{25} 192 4°; semicarbazone, m. 167°; oxime, m. 118°. Treatment of III with (iso-PrO)$_3$Al gave the corresponding alc. (IV), b_7 149 51°; *p*-nitrobenzoate, m. 79°. On distn. *in vacuo* over H_2SO_4 IV gave I, b_5 137°. I was chlorinated in HOAc and the resulting chlorohydrin distd. over KOH to give II, b_7 147–50°. II heated with the etherate of $MgBr_2$ gave a product (V), b_{10} 150 2°; semicarbazone, m. 203°; oxime, m. 156°. On oxidation V gave an acid, m. 150°, identical with phenylcyclohexylacetic acid. 1-Phenyl-2-cyclohexylethanol, b_{17} 156–7°, obtained from the action of $IMgCH_2C_6H_{11}$ on BzH when subjected to perphthalic oxidation gave the epoxide of *sym*-phenylcyclohexylethylene (VI), b_{16} 158 60°, d_4^{18} 1.003, n_D^{18} 1.003. VI heated with $MgBr_2$ etherate gave a ketone, b_{15} 163–5°, m. 26°; semicarbazone, m. 142°. This ketone was identical with cyclohexyl benzyl ketone. Rachel Brown

Allenes. I. The preparation of 1-phenyl-1,2-butadiene. Fred Acree, Jr., and F. B. LaForge. *J. Org. Chem.* **4**, 569–74(1939).—According to Staudinger and Ruzicka (*C. A.* **18**, 1819) pyrethrolone (I) has an open side chain contg. a cumulated system of double bonds but later R. (*C. A.* **28**, 3061[1]) preferred a conjugated system. Recently LaForge and Haller (*C. A.* **32**, 7438[8]) found that I gives with Br in EtOH a mono-Br substituted product from which by reduction with Zn I is recovered. Since such behavior is not in agreement with the known behavior of either cumulated or conjugated double bonds, the action of halogens on allenes, especially substituted 1,2-butadienes, is studied, for a terminal Me group may be present in the side chain of I. *1-Phenyl-1,2-butadiene* (II) is prepd. by 2 different methods. In the first the OH in PhCH(OH)CCl CHMe is replaced by Cl and the 1-phenyldichlorobutene is dehalogenated; in the second, PhCH(OH)CCl_2CHClMe is treated with Zn dust in EtOH. In contact with air, II soon turns yellow and after standing for some time it becomes a viscous mass, probably because of oxidation and polymerization. Mineral acid causes rapid polymerization or decompn. II does not react with maleic anhydride or with α-naphthoquinone. On catalytic hydrogenation II gives PhBu and on oxidation with $KMnO_4$, $PhCO_2H$ and AcOH are formed. To a Grignard reagent prepd. from 6 g. Mg and 37 g. PhBr in 200 cc. Et_2O, 23 g. α-chlorocroton aldehyde in 200 cc. Et_2O is slowly added with stirring and cooling with ice. After keeping the mixt. overnight in the cold, it is decompd. by addn. of 20 g. NH_4Cl in 300 cc. ice H_2O. The Et_2O soln., after washing with H_2O and dild. $NaHCO_3$ soln., is dried and evapd. Distn. of the residue gives 21.8 g. *1-phenyl-1-hydroxy-2-chloro-2-butene* (III), $b_{0.6-1}$ 122–4°, m. 50–1°, n_D^{25} 1.5545, n_D^{30} 1.5502. III is also formed when 10 g. 1-phenyl-2,2,3-trichloro-1-butanol in 25 cc. EtOH is dropped into a stirred suspension of 10 g. Zn dust in 25 cc. boiling EtOH. After refluxing the mixt. for 30 min. it is cooled, filtered and dild. with H_2O and extd. with Et_2O. The yield is 7.2 g. When into 4 g. III in 30 cc. cold C_6H_6, 1 g. dry HCl is passed, the excess of HCl removed by washing with H_2O and $NaHCO_3$ and the C_6H_6 removed *in vacuo*, distn. of the residue gives 3.5 g. *1-phenyldichlorobutene* (IV), either PhCH:CClCHClMe or PhCHCl-CCl:CHMe, $b_{0.7}$ 100°, n_D^{25} 1.5712, n_D^{30} 1.5666. When the chlorination is carried out with SO_2Cl_2 *1-phenyl-2,3-dichloro-1-butene* is the main product formed, $b_{0.5-1}$ 82 7°, n_D^{25} 1.5727. Dehalogenation of IV is carried out by addn. of 12 g. Zn dust in small portions to 12 g. IV in 100 cc. hot EtOH. After refluxing the mixt. for several min. it is filtered, freed from the EtOH *in vacuo*, dild. with H_2O and extd. with Et_2O. After washing and drying, the Et_2O is distd. off and the residue fractionated, with a 15-cm reflux column. I is obtained in 4.5-g. yield, $b_{0.5-1}$ 44 7°, n_D^{25} 1.5754, $n_F^{25} - n_C^{25}$ 0.025, n_D^{30} 1.5698, $d_4^{26.5}$ 0.9240. *1-Phenyl-2,2,3-trichlorobutanol* (V), $b_{0.5}$ 140–5°, m. 53°, $n_D^{25.7}$ 1.5627, is prepd. according to Helferich and Besler (*C. A.* **19**, 241). When 50 g. V is treated with 50 g. PCl_5, the cooled mixt. warmed for a few min., ice added and the product extd. with Et_2O, the latter washed with H_2O and $NaHCO_3$ soln., dried and distd., 48 g. *1-phenyl-1,2,2,3-tetrachlorobutane* (VI), $b_{0.5-1}$ 122–5°, n_D^{30} 1.5625, is obtained. VI (10 g.) when treated with Zn dust in EtOH yields 3.7 g. I, b_{10} 76–7°, n_D^{21} 1.5716. F. E. Brauns

Electronic interpretation of the halogenation of toluene. A. P. Kreshkov. *J. Gen. Chem.* (U. S. S. R.) **9**, 1251–7 (1939).—Review and discussion with 30 references. John Livak

The separation of the isomeric dinitro-1,4-dibromobenzenes and their reactions with *p*-phenylenediamine. C. J. Sunde, Gestur Johnson and C. F. Kade. *J. Org. Chem.* **4**, 548–54(1939).—Nitration of *p*-$C_6H_4Br_2$ (I) gives a mixt. of isomeric dinitro derivs. from which Austen (*Ber.* **8**, 1182 (1875); **9**, 621, 918 (1876)) isolated *1,4-dibromo-2,6-dinitrobenzene* (II), Calhane and Wheeler (*Am. Chem. J.* **22**, 449 (1899)) *1,4-dibromo-2,3-dinitrobenzene* (III) and Jackson and Calhane (*Am. Chem. J.* **28**, 451 (1902)) *1,4-dibromo-2,5-dinitrobenzene* (IV). Since II is obtained according to A. only with difficulty, the method of sepn. is improved. I (200 g.) is nitrated according to J. and C. The crude mixt. (250 g.) is dissolved in 425 cc. hot AcOH and allowed to stand in a cool place overnight. The crystals formed are filtered and 100 cc. AcOH is distd. off from the filtrate. On standing overnight a 2nd crop is obtained, another 100 cc. AcOH is distd. off from the filtrate and a 3rd crop is formed. The total yield of III is 35 g., m. 159–60° after 2 crystns. from AcOH. To the filtrate 800 cc. H_2O is added whereupon an oil seps. which solidifies on cooling. It is filtered and thoroughly washed with H_2O. The dried material (200–15 g.) is dissolved in 500 cc. hot dioxane. After standing overnight the crystals formed are filtered off, 160 cc. of the filtrate is distd. off under reduced pressure and a 2nd crop is obtained. Another 150 cc. dioxane is then removed by distn. and a 3rd crop is formed, giving a total yield of 66 g. crude IV. On purification by 2 crystns. from EtOH, 30–5 g. pure IV, m. 126–7°, is obtained. The mother liquor of IV is then concd. by distg. off 100 cc. dioxane and on standing 30 g. crude II, m. 70–80°, is obtained which after 5 crystns. from EtOH gives 16 g. pure II, m. 119–20°. From the mother liquor another 5.5–8 g. II is isolated. When 0.5 g. II is heated with 8 cc. EtOH, 0.5 g. KNO_2 and 4 cc. H_2O on a water bath, and the mixt. after standing overnight is acidified with 12 *N* HCl, *4-bromo-2,6-dinitrophenol*, m. 74–5°, is formed in

98% yield. III (1 g.) when refluxed with 1 mol. (0.330 g.) *p*-$C_6H_4(NH_2)_2$ (V) in EtOH in the presence of 0.44 g. K_2CO_3, 0.1 g. KI and 0.05 g. Cu bronze in 40 cc. MeOH according to Goldberg (*C. A.* **2**, 535) gives *3,6-dibromo-2-nitroanisole* (VI), m. 82.5–3°, in 5% yield. VI is also formed in the absence of V and by the action of MeONa on III. When a mixt. of 1 g. III, 3 g. (excess) V, 0.44 g. K_2CO_3, 0.1 g. KI and 0.05 g. Cu bronze is refluxed for 5–6 min., and the hot filtered mixt. is dild. with 100 cc. H_2O, *3,6-dibromo-2-nitro-4'-aminodiphenylamine*, m. 146–7° after crystn. from MeOH, is formed. IV (1 g.) when refluxed for 1 hr. with 0.330 g. V in 40 cc. EtOH in the presence of 0.1 g. AcONa loses 1 Br and gives 0.3 g. *4-bromo-2,5-dinitro-4'-aminodiphenylamine* (VII) as dark-blue crystals, m. 180–1° after 2 crystns. from dil. EtOH and once from $CHCl_3$. Its *Ac deriv.* (VIII), dark-red crystals, m. 227–8°. It is impossible to replace the 2nd Br. With an excess of V, IV gives a dark-red ppt., m. 235–7°, which after acetylation gives the *tetra-Ac deriv.* of the *Bandrowski base*, m. 293–4°. VIII (0.3 g.) when refluxed for 1 hr. with 3 g. V in 50 cc. EtOH forms a condensation product by replacing a NO_2 group as a dark-red cryst. product, m. 245–6°. When 1 g. II is refluxed with 0.6 g. V and 0.3 g. AcONa in 40 cc. EtOH for 15 min. *4-bromo-2,6-dinitro-4'-aminodiphenylamine* (IX), m. 193–4°, is obtained in 98% yield. Its *Ac deriv.* (X) m. 271–2°. X does not further react with V. When, however, 2 mols. II and 1 mol. V are refluxed in EtOH, *N,N'-bis(2,6-dinitro-4-bromophenyl)-p-phenylenediamine* (XI), m. 276–7°, is formed. XI is also obtained when 0.2 g. IX and 0.4 g. II are refluxed with 0.2 g. AcONa in 25 cc. EtOH for 2 hrs. In both condensation products the Br between the 2 NO_2 groups in the *o*-positions is replaced. IX is also obtained when 1 g. 1-chloro-4-bromo-2,6-dinitrobenzene (XII), 0.68 g. V and 0.5 g. AcONa in 30 cc. EtOH are refluxed for 15 min. XI is further formed when 0.2 g. IX, 0.4 g. XII and 0.2 g. AcONa in 25 cc. EtOH, or when 0.5 g. XII, 0.095 g. V and 0.3 g. AcONa in 25 cc. EtOH are refluxed for 25 min. F. E. Brauns

The structure of diazoamino salts. F. P. Dwyer. *Australian Chem. Inst. J. & Proc.* **6**, 348–61(1939).—The malenoid-fumaroid color theory of diazoamino salts proposed by Mangini and Dejudicibus (*C. A.* **28**, 1672[9]; **29**, 6580[9]) has been found to be untenable on the grounds that the colored forms described by them arise either by the use of impure diazoamino compds. or by the formation of impurities during the prepn. of the salts. The *Hg* and *K salts* of *PhN₂NHPh*, the *Hg salt* of *diazoaminoazobenzene*, the *Ag salt* of *3-nitrodiazoaminobenzene* and *3-nitrobenzenediazoaminoazobenzene*, the *Hg* and *Ag salts* of *4-nitrodiazoaminobenzene*, the *Ag salt* of *4-nitrobenzenediazoaminoazobenzene*, the *Ag* and *K salts* of *2,2'-dinitrodiazoaminobenzene* and the *Ag* (I) and *K salts* of *3,3'-dinitrodiazoaminobenzene* are prepd. It is found that I exists only in the yellow triazene form and that purified diazoamino compds., whether unsubstituted or with 1 or more Me groups, give no color with alc. alkali and yield only yellow salts. Pure nitrodiazoamino compds., however, with at least 1 NO_2 group in an *o*- or *p*-position give intensive colors with alc. alkali and the intensity of the color increases with 2 NO_2 groups in these positions. With 1 or 2 NO_2 groups in the *m*-position, an orange color is produced with alc. alkali. Diazoamino compds. with NO_2 groups in the *o*- or *p*-position are absorbed strongly on $Mg(OH)_2$ and give brilliantly colored lakes, while *m*-nitro derivs. are absorbed only feebly. PhN_2NHPh itself and its Me-substituted derivs. do not show any absorption or color formation. Methylation of the labile H in the NH group causes loss of salt-forming properties and the derivs. give no color with alc. alkali nor are they absorbed on $Mg(OH)_2$. The normal forms of 2,2'- and 4,4'-dinitrodiazoaminobenzene are yellow, the aci forms are red and purple, resp. The purple and the yellow forms of the Ag and Cu salts of 4,4'-dinitro compds. correspond to the aci and normal forms of the diazoamino compd. On the basis of these results, a theory of the structure of diazoamino salts is put forward. The colored salts which can be obtained only from *o*- and *p*-nitro compds. have the metal joined electrovalently with the O of the NO_2 group and coordinated with the triazene N. The color is caused by the *o*- or *p*-quinoid structure. Among *m*-nitro compds. and PhN_2NHPh itself and the Me derivs., the triazene structure, in which the metal is joined electrovalently to the triazene N in the "1" position and is coördinated with the N in the "3" position, is the only one possible. These salts are yellow or orange. Of the *m*-nitro compds. a 2nd type of structure is possible when the metal is strongly electropos., in which case the metal is coördinated with the O of the NO_2 group. **The isomerism of diazoamino salts.** *Ibid.* 362–8.—In the above paper it was found to be impossible to sep. the isomeric Ag salts $PhN.N:NC_6H_4NO_2(p)$ and $PhN:N.NC_6H_4NO_2(p)$. A possible solution of the question was, however, to fix 1 of the isomerides as the pyridine-coördinated isonitro acid salt $PhN:N.N:C_6H_4(:O).O$, then to revert it to the triazene form by loss of the stabilizing pyridine group and to det. the position of the Ag atom by methylation. This attempt was unsuccessful with the 4-nitro compd. but with the *3,4'-dinitrodiazoaminobenzene* (II) (cf. Meldola and Streatfeild, *J. Chem. Soc.* **51**, 102 (1887); **53**, 668 (1888)) it was found possible to settle the question by this method. The Ag salt of II exists in 2 forms, *m*-$NO_2C_6H_4N.N:NC_6H_4NO_2(p)$ (III) and *m*-$NO_2C_6H_4N:N.N:NC_6H_4NO_2(p)$ (IV) but only IV gives a *pyridine-coördinated salt* (V) of the isonitro acid and on heating at 100° or warming with Me_2CO, V should revert into IV if the isomerism is stable. Methylation of IV with MeI should give *N*-methyl-4,3'-dinitrodiazoaminobenzene (VI) which may also be obtained by coupling diazotized *m*-$NO_2C_6H_4NH_2$ with *p*-$NO_2C_6H_4NHMe$. If, however, the isomerism is dynamic, V should be converted into a mixt. of III and IV and on methylation yield a mixt. of *N*-methyl-3,4'-dinitrodiazoaminobenzene, also obtainable from diazotized *p*-$NO_2C_6H_4NH_2$ and *m*-$NO_2C_6H_4NHMe$, and of VI. When the purplish red V, isolated from pyridine at °, is warmed it loses pyridine and is reverted to the yellow triazene form which on methylation gives a mixt. of 2 *N*-Me derivs. m. 153–7°, indicating that the isomerism is actually dynamic. Similarly *4-nitrodiazoaminobenzene* gives a red isonitro acid salt which on losing pyridine is reverted into the yellow triazene form and gives on methylation a *N*-Me deriv. (VII), m. 94–5°. Hydrolysis of VII with HCl and CuCl gives a mixt. of *p*-$NO_2C_6H_4NHMe$, PhNHMe, PhCl and *p*-$NO_2C_6H_4Cl$, indicating that VII is a mixt. of 2 isomeric forms. This shows that the isomeric Ag salts of unsym. triazene 4-nitrodiazoaminobenzene are in a dynamic state. F. E. Brauns

Reactivity of the aromatic nucleus. I. Karrer's theory of coupling. W. J. Hickinbottom and E. W. Lambert. *J. Chem. Soc.* **1939**, 1383–6(1939).—Karrer (*C. A.* **9**, 3239) has reported that $(iso\text{-}Bu)_2NPh$ (I) or $(iso\text{-}Am)_2NPh$ (II) reacts in aq. AcOH with *p*-$HO_3SC_6H_4N_2X$ (III) to form *p*-$HO_3SC_6H_4N_2C_6H_4NHR$ (R = iso-Am or iso-Bu) with the elimination of an alkyl group. It has not been possible to repeat these results, the amines reacting normally with III. II (1.5 g.) in 5 cc. AcOH, cooled and stirred while III from 1.5 g. of the acid was added gradually, followed by AcOK, gives on addn. of KOH the *K salt* of 4-diisoamylaminoazobenzene-4'-sulfonic acid, yellow-orange, glistening plates. Reduction with $Na_2S_2O_4$ in alk. soln. gives *p*-aminodiisoamylaniline (IV), whose *HCl salt* is formed in Et_2O; an aq. soln. gives a brilliant-red color with $FeCl_3$, quickly fading to yellow. The *Bz deriv.* of IV m. 101°. II and *p*-$O_2NC_6H_4N_2Cl$ (V) gives *4'-nitro-4-diisoamylaminoazobenzene*, crimson, m. 120°. III and (iso-Am)NHPh (VI) in AcOH give the *K salt* of 4'-isoamylaminoazobenzene-4-sulfonic acid, golden-orange plates; reduction gives *p*-aminoisoamylaniline, whose

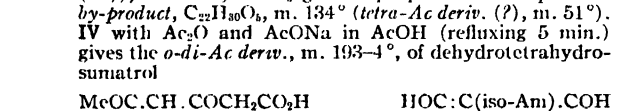
di-HCl salt forms plates; $FeCl_3$ gives a green color. V and VI give *4'-nitro-N-isoamyldiazoaminobenzene*, yellow, m. 72–3°; the corresponding aminoazo compd. could not be isolated. I and III give the *K salt* of 4-diisobutylaminoazobenzene-4-sulfonic acid, orange-brown crystals; reduction yields *p-aminodiisobutylaniline* (VII), the *HCl salt* of which m. 223–4°; $FeCl_3$ gives an intense-red color, rapidly fading to yellow; *Bz deriv.* of VII, m. 111°. I (2.1 g.) in 1:2 HCl, cooled and treated with 1.6 cc. 48% aq. $NaNO_2$, gives the *HCl salt*, yellow-brown needles, of *p-nitrosodiisobutylaniline*, green, m. 62–3°; reduction with Zn and dil. HCl gives VII. V and I give *4'-nitro-4'-diisobutylaminoazobenzene*, crimson, m. 122–3°. V and methyl-*tert*-butylaniline in aq. Na_2CO_3 give *4'-nitro-4-methyl-tert-butylaminoazobenzene*, crimson, m. 133–4°; *tert*-BuNHPh similarly give *4'-nitro-N-tert-butyldiazoaminobenzene*, yellow, m. 142–3°. Dioctylaniline and V give *4'-nitro-4-dioctylaminoazobenzene*, crimson, m. 66–7°; octylaniline yields *4'-nitro-N-octylaminodiazoaminobenzene*, yellow, m. 61–2°. Cetylaniline gives *4-nitro-N-cetyldiazoaminobenzene*, pale yellow, m. 77°; V and dicetylaniline give *4'-nitro-4-dicetylaminoazobenzene*, bright red, m. 70–1°. *N*-Dialkylanilines may be purified by crystn. of the picrates; the method fails if the alkyl group is too large. $PhNH_2$ (25 g.) and 50 g. iso-AmBr, refluxed 2 hrs. at 120° and 1 hr. at 140°, the liberated amines distd. and the fraction b. above 190° (43.9 g.) heated again with 25 g. iso-AmBr for 3 hrs. at 100° and 5 hrs. at 140° and the operation repeated by heating 7 hrs. at 150° and the fractions b. above 260° converted into picrates and crystd. from EtOH, give the pure *picrate*, yellow, m. 146°; the yield of II is 21.5 g. I gives a *picrate*, yellow, m. 141°; *that* of dimethyl-*p*-xylidene, yellow, m. 159–60°, and *that* of 2-dimethylamino-*m*-xylene, yellow, m. 154–5°; *that* of *o*-$ClC_6H_4NH_2$ m. 133–4°. C. J. West

Hydrolysis of substituted benzenesulfonanilides. IV. Solubility of sulfonanilides in water and hydrochloric acid. R. L. Shriner, J. D. Oppenlander and R. S. Schreiber. *J. Org. Chem.* 4, 588–92(1939); cf. *C. A.* 28, 5052[3].—Since *N*-alkylbenzenesulfonanilide is hydrolyzed in about 1/3 the time required for the hydrolysis of an unsubstituted benzenesulfonanilide (cf. *C. A.* 28, 1674[4]) it was thought that the soly. might play an important role. The detn. of the soly. of *benzenesulfonanilide*, its *N-Me*, *N-Et*, m. 37–8°, *N-Pr* and *N-Bu derivs.*, b. 182–4°, m. 33°, *p-toluenesulfonanilide* (II), its *N-Me*, *N-Et*, *N-Pr* and *N-Bu derivs.* in H_2O and const.-boiling HCl, shows that the soly. of each series in either solvent decreases as the size of the alkyl group increases, and the ratio of the soly. in HCl to that in H_2O is not only greater than 1.0 but rises to a max. value and then decreases. The increase in soly. of the *N*-alkylarylsulfonanilides in HCl may be one of the reasons why they are hydrolyzed by acids more rapidly than their unsubstituted derivs. F. E. Brauns

The action of nitrous acid on certain halogenated substitution products of 2,5-, 3,4- and 3,5-dimethylphenols. L. Chas. Raiford and Donald W. Kaiser. *J. Org. Chem.* 4, 555–68(1939).—Earlier expts. on the action of HNO_2 on brominated phenol and cresol (cf. Zincke, *J. prakt. Chem* [2], 61, 561 (1900), R. and Miller, *C. A.* 27, 2943, and R. and Scott, *C. A.* 32, 924[1]) showed that Br in a favorable position to the OH group can be replaced by a NO_2 group. It was desired to prep. for comparison 2-nitro-4,6-dibromo-*m*-xylenol and to exam. the behavior of tri-Br substitution products of other xylenols. *2,5-Dimethyl-3,4,6-tribromophenol* (I), prepd. according to Auwers and Erckientz (*Ann.* 302, 114, (1898)), (250 g.) is dissolved in a mixt. of 3 l. AcOH and 200 cc. dioxane, cooled to 7–10° and 12 g. $NaNO_2$ is added within 2 hrs. After keeping the mixt. overnight it is poured with rapid stirring into 18 l. H_2O and the *2,5-dimethyl-3,6-dibromo-4-nitrophenol* (II) is filtered. The yield is 81%. II m. 152–3° (decompn.) after crystn. from ligroin. The Br at C atom 4 (OH = 1) is therefore replaced by a NO_2 group. Methylation of II with Me_2SO_4 and KOH gives *2,5-dimethyl-3,6-dibromo-4-nitrophenyl Me ether*, m. 85–6°, in 58% yield. The *Ac deriv.* of II m. 114–15°. Oxidation of II by slow addn. of 10 g. to 50 cc. fuming HNO_3 at 0°, warming the mixt. to room temp., followed by heating for 5 min. on a water bath and pouring the mixt. into ice H_2O gives *3,6-dibromo-p-xyloquinone*, m. 185–6°, in 58% yield. Reduction of II with $SnCl_2$ according to R. and Colbert (*C. A.* 19, 1858) gives *2,5-dimethyl-3,6-dibromo-4-aminophenol-HCl* (III) in 72% yield. III decomps. at about 225°. The *free base* (IV) of III is isolated with $(NH_4)_2CO_3$ and m. 187–8° (decompn.). To prove that II is a 4-nitrophenol, the following acyl derivs. of IV are prepd: *N,O-di-Ac*, in 77% yield, m. 237–8°; *acetylaminophenol*, 89% yield, m. 230–1° (decompn.); *N,O-di-Bz*, 86% yield, m. about 275°; *benzoylaminophenol*, 92% yield, m. 221–2°; *N-benzoyl-O-acetyl*, 73% yield, m. 224–5°; and *N-acetyl-O-benzoyl* 72% yield, m. 250–1°. 3,4-Dimethylphenol is nitrated by addn. of a mixt. of 15 cc. concd. HNO_3 and 50 cc. AcOH to a soln. of 10 g. in 100 cc. AcOH and pouring the mixt. after 1 min. into 5 vols. ice H_2O. On fractional crystn. *3,4-dimethyl-6-nitrophenol* (V), m. 86–7°, is obtained in 19% yield in addn. to the *2,6-dinitro deriv.*, m. 126–7°. By steam distn. of the crude nitration product, V is obtained in 38% yield. To decide whether the NH_2 group is in the 2- or 6-position, V is brominated by addn. of 21 g. Br in 10 cc. AcOH to 10 g. V in 40 cc. AcOH in the presence of 0.5 g. Fe powder. *2-Bromo-3,4-dimethyl-6-nitrophenol* (VI), m. 74–5°, is so obtained in 82% yield. On reduction with $SnCl_2$ *2-bromo-3,4-dimethyl-6-aminophenol-HCl* (VII) is formed in 74% yield. VII decomps. at about 260°; *free base* (VIII), m. 103–4°; *Ac deriv.*, m. 199–200°. Attempts to introduce a 2nd Br atom into VII failed. 3,4-Dimethylphenol on bromination with Br gives *2,5,6-tribromo-3,4-dimethylphenol* (IX), m. 173–4°. Nitration of IX with $NaNO_2$ in AcOH gives *2,5-dibromo-3,4-dimethyl-6-nitrophenol* (X), m. 168–9° (decompn.), in 61% yield. Its *Me ether*, prepd. with Me_2SO_4 in 67% yield, m. 100–1°. Reduction of X with $SnCl_2$ yields *2,5-dibromo-3,4-dimethyl-6-aminophenol-HCl* (XI) in 87% yield. XI decomps. about 230° without melting. The *free base* (XII) m. 130–1°. XII is further characterized by the following acyl derivs: *N,O-di-Ac*, 82% yield, m. 117–18°; *acetylaminophenol*, 90% yield, m. 181–2°; *N,O-di-Bz*, 85% yield, m. 207–8°; *benzylaminophenol*, 90% yield, m. 227–8°; and *N-benzoyl-O-acetyl*, 62% yield, m. 209–10°. Only 1 mixed Ac-Bz deriv. is obtained independent of the order of introduction of acyl groups, the heavier radical being attached to N (cf. *C. A.* 20, 1073). Since on nitration of *sym*-tribromo-*m*-xylenol a 4-NO_2 compd. is formed, the isomeric 2-NO_2 deriv. is prepd. by bromination of 20 g. 2-nitro-3,5-dimethylphenol in 100 cc. AcOH at 100° with 13 cc. Br. *2-Nitro-3,5-dimethyl-4,6-dibromophenol* (XIII), obtained in 90% yield, m. 160–1° (decompn.), its *Me ether* m. 99–100°. Reduction of XIII gives *2-amino-3,5-dimethyl-4,6-dibromophenol-HCl* (XIV) in 89% yield which decomps. at about 241°; *the free base* (XV) m. 141–2°. Only 1 Ac-Bz deriv. is obtained from XV. The following acyl derivs. are prepd: *N,O-di-Ac*, 78% yield, m. 244–5° (decompn.); *acetylaminophenol*, 91% yield, m. 190–1°; *N,O-di-Bz*, 87% yield, m. 178–9°; *benzoylaminophenol*, 93% yield, m. 224–5° (decompn.); and *N-benzoyl-O-acetyl*, 64% yield, m. 175–6°. Since Cl is not replaced by NO_2 when the Zincke method is used, the behavior of *2,4,6-trichloro-3,5-dimethylphenol* (XVI) toward HNO_3 is examd. XVI is prepd. in 87% yield by passing Cl into 122 g. 3,5-dimethylphenol in 1.5 l. hot CCl_4, XVI m. 177–8°. Treatment of XVI with fuming HNO_3 according to Kohn and Rabinowitsch (*C. A.* 21, 3606) gives no NO_2 deriv. but *2,6-dichloro-m-xyloquinone* (XVII) in 87% yield, m. 177–8°. With H_2NOH in alc. XVII yields *2,6-dichloro-m-xyloquinhydrone* (XVIII), m. 177–8°. Reduction of XVII by treating it with 2 mols. H_2NOH or with $SnCl_2$ gives *2,6-dichloro-m-xylohydroquinone* (XIX) in 86% yield, m. 225–6°. When to 100 g. XVI in 1.8 l. AcOH, 50 g. $NaNO_2$ is added in small portions within 1 hr. at room temp. and the mixt. allowed to stand overnight, a *mol. compd.* consisting of 1 mol. XVII and 2 mols. XVI is formed in 48% yield. It turns yellow at 118–19° without melting and m. between 133 and 164° to a yellow liquid. F. E. Brauns

Action of alcoholic monomethylamine on derivatives of

benzoquinone and toluquinone. I. The methoxy- and hydroxymethoxy derivatives. W. K. Anslow and H. Raistrick. *J. Chem. Soc.* **1939**, 1446–57.—The following work grew out of an attempt to synthesize 3,6-dihydroxy-4-methoxy-2,5-toluquinone (I) (spinulosin, *C. A.* **32**, 7955[9]) by the interaction of alc. $MeNH_2$ and 4-methoxytoluquinone and hydrolysis of the resulting methylamino deriv. Instead of the expected 3,6-bis(methylamino)-4-methoxytoluquinone, however, *2,5-bis(methylamino)-1,4-benzoquinone* (II), cerise, m. 284–6° (decompn.), was formed, which gives 2,5-dihydroxy-1,4-benzoquinone on hydrolysis. Benzoquinone, its MeO and its 2,5-di-MeO derivs. likewise give II. 2,6- and 2,3-Dimethoxy-1,4-benzoquinone and 4,6-dimethoxytoluquinone give with $MeNH_2$ *2,5-bis(dimethylamino)-3-methoxy-1,4-benzoquinone* (III), steel-gray, m. 234°. Toluquinone, the 3- and 6-MeO and the 3,6-di-MeO derivs. give 3,6-bis(methylamino)-2,5-toluquinone (IV), purple-brown, m. 231°. 3,4-Dimethoxytoluquinone and the 3,4,6-tri-MeO deriv. give the *4-MeO deriv.* of IV, purple-gray, m. 231° (partial sublimation); it gives a deep-purple color in $CHCl_3$. Hydrolysis of III and acetylation give *2,5-diacetoxy-3-methoxy-1,4-benzoquinone*, lemon-yellow, m. 77°. I and CH_2N_2 in Et_2O or Me_2SO_4 and K_2CO_3 in Me_2CO give *3,4,6-trimethoxy-2,5-toluquinone*, reddish orange, m. 80°, which gives a deep-blue color with concd. H_2SO_4; reduction with $Na_2S_2O_4$ gives a nearly quant. yield of *2,5-dihydroxy-3,4,6-trimethoxytoluene*, m. 82–3°; cold concd. H_2SO_4 gives a bright-yellow color, changing to a dark olive-green in 30 min.; $FeCl_3$ gives a golden-yellow color. $1,2,4,5\text{-}(AcO)_4C_6H_2OMe$, boiled with MeOH-$H_2SO_4$ for 0.75 hr. in a N atm. and the quinol oxidized with air at pH 8 for 10 min., gives *2-hydroxy-5-methoxy-1,4-benzoquinone* (V), orange-brown, m. 179° (decompn.); it sublimes at 100° in a high vacuum; concd. H_2SO_4 gives a dull-red color and EtOH-$FeCl_3$ a deep reddish brown color; Ac_2O-H_2SO_4 gives the *2-Ac deriv.*, lemon-yellow, m. 124°; V and $MeNH_2$ give *4,5-bis(dimethylamino)-1,2-benzoquinone* (?), dark-purple, does not m. 360°. $1,4,5,2,3\text{-}(AcO)_3C_6H(OMe)_2$ with MeOH-H_2SO_4, followed by oxidation with air at pH 8 for 30 min., gives *5-hydroxy-2,3-dimethoxybenzoquinone* (VI), reddish orange, m. 125–6°; cold concd. H_2SO_4 gives an intense blue color and $FeCl_3$ an intense reddish brown color. VI with $MeNH_2$ gives the *$MeNH_2$ salt*, dark-purple, m. 228–30° (decompn.), of *2-methylamino-5-hydroxy-3-methoxybenzoquinone*, purple-black, m. 179° (decompn.), which gives a purple soln. in $CHCl_3$ and 0.1 *N* NaOH and an olive-brown color with $FeCl_3$. Reduction of VI with $Na_2S_2O_4$ gives *1,4,5-trihydroxy-2,3-dimethoxybenzene*, m. 157–8°; H_2SO_4 gives a canary-yellow color, quickly changing through yellow-green to emerald-green; $FeCl_3$ gives an intense reddish brown (I) color. 2,5-Dihydroxy-3-methoxy-1,4-benzoquinone (VII) and $MeNH_2$ give the *di-$MeNH_2$ salt* of VII, violet, m. 214° (decompn.). 3-Hydroxy-4-methoxy-2,5-toluquinone (Fumigatin) and $MeNH_2$ give the *6 $MeNH_2$ deriv.*, coppery-purple, m. 213–14°; $CHCl_3$ gives a deep-purple soln.; $FeCl_3$ gives an intense olive-green color; hydrolysis gives I. 6-Hydroxy-4-methoxy-2,5-toluquinone and $MeNH_2$ probably give *5,6-bis(methylamino)-4-methoxy-2,3-toluquinone*, olive-green, m. 228°; hydrolysis yields I. H_2SO_4 gives a deep blue-violet soln. 3-Methoxy-2,5-toluquinone with Ac_2O and H_2SO_4 gives *2,5,6-triacetoxy-3-methoxytoluene*, m. 155°; hydrolysis and air oxidation yield *6-hydroxy-3-methoxytoluquinone* (VIII), golden-yellow, m. 155–6°; concd. H_2SO_4 gives a reddish violet color and $FeCl_3$ a purple color. $MeNH_2$ gives *3-methylamino-6-hydroxy-2,5-toluquinone*, dark purple-red, m. 252–4°; H_2SO_4 gives a crimson soln. and $FeCl_3$ an intense purple-brown color. Reduction of VIII yields *2,5,6-trihydroxy-3-methoxytoluene*, m. 102–3°, which acquires a purple color in the air; concd. H_2SO_4 gives an orange-yellow color, changing through apple-green to emerald-green; $FeCl_3$ gives an olive-brown, changing to a purple color. *6-Ac deriv.* of VIII, yellow, m. 109°. A cryst. product could not be obtained from 4-hydroxy-6-methoxy-2,5-toluquinone and $MeNH_2$. 3,6-Dihydroxy-4-methoxy-2,5-toluquinone yields the *bis-$MeNH_2$ salt* of I, violet, m. 173°; cold 2 *N* H_2SO_4 gives I. 3,4-Dimethoxytoluquinone gives an oily acetylation product; hydrolysis and oxidation yield *6-hydroxy-3,4-dimethoxy-2,5-toluquinone* (IX), tomato-red, m. 105°; concd. H_2SO_4 gives a blue-green color and $FeCl_3$ a brownish purple color; $MeNH_2$ yields *3-methylamino-6-hydroxy-4-methoxy-2,5-toluquinone*, purple-black, m. 212–13°; $CHCl_3$ gives a purple ($KMnO_4$) soln. and 0.1 *N* NaOH a deep-violet soln.; $FeCl_3$ gives an intense olive-green color. Reduction of IX yields *2,5,6-trihydroxy-3,4-dimethoxytoluene*, m. 110–11°; concd. H_2SO_4 gives a golden-yellow, changing to a deep emerald-green color; $FeCl_3$ gives a brownish purple color. In those cases above where 2 MeO groups are replaced by 2 $MeNH_2$ groups, the yields approximate 100%; where only 1 MeO group is replaced, the yield is 50%; with benzo- and toluquinones the yields were 33%. The mechanism of the reactions is discussed.
C. J. West



Nitrosation of phenols. XVI. *m*-Fluorophenol. A new red indophenol. Herbert H. Hodgson and Donald E. Nicholson. *J. Chem. Soc.* **1939**, 1405–8; cf. *C. A.* **27**, 4225.—*m*-FC_6H_4OH (I) behaves exceptionally toward HNO_2 in H_2O in that reaction occurs in the 6-position instead of the normal 4-position, as with the other *m*-halogen derivs. Probably 5,2-$F(ON)C_6H_3OH$ is first formed but this immediately condenses with unchanged I to form a *m,m'-difluoro-o-indophenol* (II), red-brown, very stable to acids. In 30% aq. AcOH at room temp. pptn. of II occurs continuously over several days until an almost quant. yield is obtained; at 100° the reaction is immediate and it is also more rapid when carried out in H_2SO_4. In all cases a small quantity of 5,2-$F(O_2N)C_6H_3OH$ is formed by a simultaneous reaction. The structure of II is established by a comprehensive series of color reactions. II on reduction with Zn and AcOH gives a leuco compd., which is oxidized by air to a blue soln., giving a red color with $FeCl_3$. The reaction of I is compared with that of *m*-$MeOC_6H_4OH$ and both are explicable on electronic grounds.
C. J. West

Aromatic amines and 3-nitro-6-bromonitrostyrene. David E. Worrall and Jack Finkel. *J. Am. Chem. Soc.* **61**, 2969–70(1939).—Following the work on 2-chloronitrostyrene (*C. A.* **33**, 1284[9]), the behavior of the Br deriv. has been studied; the 2 compds. have almost identical chem. properties. Reaction of BrC_6H_4CHO, Et_3N and $MeNO_2$ at 25–30° gives 60% of *α-nitro-β-(2-bromophenyl)ethylene* (I), yellow, m. 84°; fuming HNO_3 gives the *6-bromo-3-nitrophenyl analog* (II), pale yellow, m. 114.5° (oxidation gives 6,3-$Br(O_2N)C_6H_3CO_2H$); Br gives the *α-Br deriv.* (III) of II, yellow, m. 146–7°; *α-Cl deriv.*, yellow, m. 140–1°. I in hot EtOH with 0.5 equiv. of *p*-$C_6H_4(NH_2)_2$ gives *N,N'-[α,α'-di(2-bromophenyl)-β,β'-dinitrodiethyl]-p-phenylenediamine*, yellow, m. 146–7°; III but not II forms an addn. product with *p*-$MeC_6H_4NH_2$, yellow, m. 103–4°. The following *β-derivs.* of *α-nitro-β-(6-bromo-3-nitrophenyl)ethane* were prepd.: *o-*, *m-* and *p-toluidino*, yellow, m. 108–9°, 103–4° and 132–3°; *o-*, *m-* and *p-anisidino*, yellow, m. 139–40°, 159–60° and 105–6°; *p-phenetidino*, yellow, m. 134–5°; *p-dimethylaminoanilino*, yellow, m. 140–1°; *phenylhydrazino*, yellow, m. 147–8°. *Bis(α-(6-bromo-3-nitrophenyl)-β-nitroethyl)amine*, $C_{16}H_{13}Br_2N_5O_8$, m. 146–7°; the *N,N'-bis[α-(6-bromo-3-nitrophenyl)-β-nitroethyl]-p-phenylenediamine* and *-benzidine compds.*, orange, have indefinite m. ps.
C. J. West

Phototropy of anils and a note on the phototropy of solutions of the leucocyanides of malachite and brilliant greens. V. De Gaouck and R. J. W. Le Fèvre. *J. Chem. Soc.* **1939**, 1457–65.—Of 300 known anils only 25 have been reported to show phototropy and of these 18 are derivs. of *o*-HOC_6H_4CHO and 3 of *p*-HOC_6H_4CHO. A study of various anils, such as salicylidene-*m*-toluidine in soln., spectrophotometrically and dielectrically, shows that phototropism of anils is a reaction which occurs *only* in the solid state; in soln. no such change of color or other properties can be produced by illumination. X-ray studies and photomicrographs show that the phototropic mechanism must consist in a mutual interaction of moles in the lattice and not in some rearrangement undergone by them. In

compds. of the type 4,2-X(OH)$C_6H_3CH{:}NC_6H_2Y_3$, it is shown that if X is any other group than H, phototropism does not occur; the elec. specification of X seems to be irrelevant—it may be either $+I$ or $\pm I \pm T$; the influence of Y upon the phototropic process is very marked, for although salicylidene-*m*-toluidine, -aniline and -*p*-bromoaniline give θ values in the ratios 1·2 3, yet the *o*- and *p*-toluidines and *p*-chloroaniline underwent no apparent color changes. The light used has some effect; salicylideneaniline (I) shows little color development in sunlight, but if the light is first passed through a blue filter a strong color change—from light yellow to reddish brown—is induced in the anil which is thus evidently very sensitive to the reversing action of the longer waves. Absorption spectra are given for salicylidene-*o*-, -*m*- and -*p*-toluidines, -*p*-bromo and -*p*-chloroanilines, the *o*-MeO, 5-Br, 5-NO_2 and 5-Me derivs. of I and 5-chlorosalicylidene-*m*-toluidine. An app. is described and illustrated for the dielec. examn. of phototropic changes in soln. The phototropic changes described in the literature for the leucocyanides of malachite green (II) and brilliant green (III) have been confirmed when EtOH is the solvent; however, no effect was observed in C_6H_6. The dipole moment of II, III and the leuco base of malachite green, obtained from solns. in C_6H_6, are 1.1$_3$, 1.7$_2$ and 1.5$_7$, resp. These values illustrate the facilitation of mesomerism by the R_2N group. C. J. West

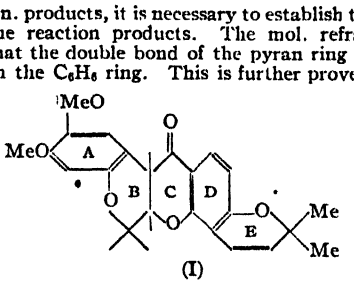
Sumatrol. II. The synthesis of dehydrotetrahydrosumatrol. Thomas S. Kenny, Alexander Robertson and Stephen W. George. *J. Chem. Soc.* **1939**, 1601–4; cf. *C. A.* **31**, 4318[9].—1,3,5-$C_6H_3(OH)_3$ (I) (16 g.) and 20 g. $AlCl_3$ in 200 cc. $PhNO_2$, treated with 13 g. of iso-BuCOCl at 0°, give 8–10 g. *phloroisovalerophenone* (II), m. 145° (*2,4-dinitrophenylhydrazone*, dark-red, m. 196°). I and iso-BuCN with HCl and $ZnCl_2$ in Et_2O give a mixt. which gives II on heating *in vacuo* at 110–15°. Clemmensen reduction of II gives *isoamylphloroglucinol* (III), m. 126°, which gives a faint-blue color with aq. $FeCl_3$. Condensation of III and 2,4,5-$NCCH_2(MeO)_2C_6H_2OCH_2CO_2Me$ with HCl and $ZnCl_2$ in Et_2O and hydrolysis of the ketimine and the resulting ester gives *4,5-dimethoxyphenoxyacetic acid-2-isoamylphloroacetophenone* (*tetrahydrosumatrolic acid* (IV)), m. 206°; $FeCl_3$ gives a purple color. A *phenolic by-product*, $C_{22}H_{30}O_6$, m. 134° (*tetra-Ac deriv.* (?), m. 51°). IV with Ac_2O and AcONa in AcOH (refluxing 5 min.) gives the *o-di-Ac deriv.*, m. 193–4°, of dehydrotetrahydrosumatrol

(V), m. 218° (cf. part I). The structure V is preferred through analogy with toxicarol; this implies that sumatrol contains the isopropylenedihydrofuran system present in rotenone. C. J. West

Alleged geometrical isomerism in certain anils and the dipole moment of phenanthridine. V. De Gaouck and R. J. W. Le Fèvre. *J. Chem. Soc.* **1939**, 1392–4.—It was shown in *C. A.* **32**, 5798[8] that the 2 crystallographically distinct varieties of salicylideneaniline are identical in C_6H_6 soln. The same is true of I and II. *p*-Homosalicylideneaniline (I), crystd. rapidly with cooling, gives a yellow form, whereas slow cooling above 32° gives an orange-red form; the yellow may be irreversibly transformed into the red modification by application of heat. Et salicylidene-*p*-aminobenzoate (II) is obtained as a yellow form by mixing concd. EtOH solns. of the components and quickly crystg. the product; slow crystn. from a dil. soln. gives a red form. The yellow form is 6-sided tables, m. 87.5°, and the red is long prisms, m. 83° (followed by immediate solidification and reversion to the yellow form). Ebullioscopically and cryoscopically both forms are unimol. in C_6H_6. The 2 forms of I have the dipole moments 2.95 and 2.91, and for II the values are 2.69 and 2.69; values for d_4^{25} and n_D^{25} are given for 4 concns. of these compds. Thus the alleged isomerism is due to dimorphism. The assumption of a trans structure for benzylideneaniline (III) depends upon the identity of moment found for it and its *p,p'*-Cl_2 deriv. The dipole moment of phenanthridine (IV) has been detd., since this should be of the order to be expected for the unknown cis modification (V) of III. The values for the dipole moment are: III 1.5$_7$ (calcd. 1.9), V 1.6 (calcd.) and IV 1.5$_0$ (calcd. 1.6); they thus differ in the sense forecast. The value of the dipole moment for benzophenoneanil is 2.0$_3$. C. J. West

A group of organo-mercury compounds, derivatives of allyl. M. Dominikiewicz and M. Kijewska. *Arch. Chem. Farm.* **4**, 8–21(in French, 21–2)(1939).—In a previous paper (cf. *C. A.* **32**, 9298[3]) it was shown that the org. component with which a radical of allylamine, substituted with Hg, is combined in diuretics, plays no part in the specific action of such compds. The diuretic effect of such compds. seems to depend only upon the substituted radical: $RNHCH_2CH(OMe)CH_2HgOH$, or $RNHCH_2CH(HgOH)CH_2OMe$. A problem arises, however, whether the carbonyl group, by means of which the allylamine radical is combined with the org. component in all the above-mentioned compds. (as, e. g., in Diluvite, *o*-$NaO_2CC_6H_4CONHCH_2CH(OMe)CH_2HgOH$ (I) or salyrgan, *p*-$NaO_2CCH_2OC_6H_4CONHCH_2CH(OMe)CH_2HgOH$ (II), has any effect upon the action of compds. having a constitution similar to that of I or II, but deprived of the linking CO group. The aminobenzoic acids (*o*- and *p*-) answer these conditions, and they were used as starting material for the syntheses described below. By heating anthranilic acid and also *p*-aminobenzoic acid with allyl bromide in alc., with addn. of K_2CO_3, the corresponding *o*- and *p*-allylaminobenzoic acids (III, IV) were obtained. III, yellowish needles from MeOH, m. 118.5–19.5°; alc. solns. of this acid show a bluish fluorescence. IV, colorless prisms from C_6H_6, m. 128–9° (for the same acid, obtained according to U. S. pat. 1,550,350 (*C. A.* **20**, 480) the m. p. 144–6° is given; the authors consider this to be an error). Besides these 2 main products, 2 others are also formed during the above reactions, viz., the allyl esters (V, VI) of III and IV. At room temp. both these compds. are oily liquids, slightly yellow and orange, resp., almost odorless, insol. in water. Solns. of V in EtOH and Et_2O show a bluish fluorescence. Both acids, III and IV, yield with $Hg(OAc)_2$ in MeOH the corresponding acetomercuri compds., $HO_2CC_6H_4NHCH_2CH(OMe)CH_2HgOAc$ (VII, VIII). VII, white powder, m. around 215° (decompn.); VIII, white powder, insol. in water. VII and VIII are sol. in alkalies with a yellow color and a bluish fluorescence; from these solns. upon satn. with CO_2 white hydroxymercuri derivs. (IX) are pptd. (the Ac group is split off and replaced by H). The *o*-aminobenzoic deriv. changes into the anhydride form, $O.CO.C_6H_4.NH.CH_2.CH(OMe).CH_2.Hg$ (X) From the above it is evident that there is a great similarity between the diuretics of the type I or II, which are derivs. of acid amides, and the derivs. of aromatic amines. In spite of this, however, the difference between both types of compds. can have as a consequence a difference in their pharmacol. and pharmacotherapeutical action. It seems to be incontestable that prepns. of type II owe their properties to the radical of allylamine substituted with Hg. Because of this it would be interesting to establish whether and to what extent their action is caused by the allylamine radical itself, and to what degree by the allyl radical as such. Syntheses of compds. derived from diallylacetic acid would help to solve this problem. Compds. of this type were prepd. by condensation of diallylacetyl chloride with *o*- and *p*-aminobenzoic acids. By direct action of the chloride upon the acids, *o*- and *p*-diallylacetylaminobenzoic acids, $HO_2CC_6H_4NHCOCH(CH_2CH{=}CH_2)_2$ (XI, XII) were obtained. XI, colorless prisms from C_6H_6, m. 108–9°, sol. in the majority of org. solvents, insol. in water. XII, white prisms from EtOH, m. 215.5–16°. In MeOH these 2 compds. yield with $Hg(OAc)_2$ the acetomercuri compds. $HO_2CC_6H_4NHCOCH[CH_2CH(OMe)CH_2HgOAc]_2$, (XIII, XIV). Both XIII and XIV are sol. in alkalies and in alk. carbonates, whereby the Ac radicals are split off and replaced by H. In that way the proper corresponding hydroxymercuri compds. (XV) are formed; they ppt.

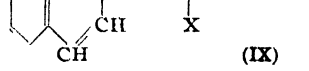
from the solns. satd. with CO_2, in form of white powders, insol. in water. The authors also tried to synthesize a deriv. of diallylacetic acid in which the radical of this acid would be connected with the aromatic nucleus not by means of an NH_2 group, as in the above described compds., but indirectly, through a carboxylic group. Thus the problem was to obtain a substituted acid amide. For this purpose diallylacetyl chloride acid was condensed with K phthalimide. Although the reaction took place with great difficulty, a small quantity of phthaldiallylacetylimide (XVI) was obtained, crystals from ligroin, m. 52°. This imide could not be transformed into a deriv. of phthalamic acid because, during its hydrolysis by heating with NaOH, it decompd. into phthalic acid, NH_3 and diallylacetic acid. This seems to prove the impossibility (already mentioned in the literature) of obtaining derivs. of a bilateral acid amide, i. e., substituted by a 2nd acid group with an open chain. The desired result was reached in a different way: XVI was substituted with Hg in MeOH by means of $Hg(OAc)_2$, and the corresponding acetomercuri deriv. $C_6H_4(CO)_2NCOCH[CH_2CH(OMe)CH_2HgOAc]_2$ (XVII) was obtained, as a snow-white powder from MeOH, softens at 138° and m. 148° (decompn.). XVII is insol. in water and in cold alkalies; on heating, however, it dissolves slowly and gives clear solns. without sepn. of Hg. That is the result of hydrolysis of the imide to the corresponding deriv. of phthalamic acid; during this hydrolysis a sol. alkali salt of the hydroxymercuri deriv. (XVIII) is formed; this compd. can be sepd. as a snow-white powder by satg. the alk. soln. with CO_2. XVII contains 47.2% Hg, and XVIII 51.17% Hg. The latter, representing a compd. of a very high Hg content, may have very interesting pharmacotherapeutical properties. E. A. Ackermann



The action of sulfur monochloride on phenylacetonitrile. V. V. Korshak and A. F. Liscenko. *J. Gen. Chem.* (U. S. S. R.) **9**, 1329-31(1939). $PhCH_2CN$ (I) (10 g.) with 93 g. S_2Cl_2 (II), allowed to stand at room temp. for 15 days, with occasional stirring, gave a mixt. of I, $PhCHClCN$, $PhCCl_2CN$ (III) and diphenylmaleonitrile (IV), m. 159-60°. By extending the time of reaction to 3 months or by heating a mixt. of 10 g. I, 10 g. III and 18 g. II on the water bath for 20 hrs. complete conversion to IV was obtained. IV sapond. with alc. KOH gave diphenylmaleic anhydride (V), yellow, m. 153°. I (58 g.) with 135 g. II refluxed on the water bath for 40 hrs. gave 30 g. *diphenyldichlorosuccinonitrile* (VI), m. 189-90°, and a small amt. of IV. VI sapond. with 10% alc. KOH gave V and with KI in Me_2CO gave IV in quant. yield. An attempt to add Br and Cl to IV proved unsuccessful.

John Livak

The preparation and properties of 3,5-diiodo-*l*-tyrosine. A. Ya. Savitskiĭ. *J. Gen. Chem.* (U. S. S. R.) **9**, 1342-4 (1939).—3,5-Diiodo-*l*-tyrosine (I) is obtained in 88% yield by treating 90.5 g. air-dried tyrosine in 1340 cc. 25% NH_4OH and 1510 cc. H_2O at 6-8° with 2025 cc. 1 *N* I soln in KI for 3 hrs. and neutralizing the reaction soln. with 670 cc. concd. HCl and SO_2 gas, and is best purified by dissolving in 2 *N* HCl, treating with norite and pptg. with concd. NH_4OH. I from aq. solns. gives the dihydrate, m. 202° (decompn.). 3,5-Diiodo-*dl*-tyrosine under the same conditions crystallizes as the monohydrate, which indicates that it is the *dl*-compd. and not a mixt. of the *d*- and *l*-forms. John Livak



New synthetical methods in coumarin chemistry. R. C. Shah. *Proc. Natl. Inst. Sci. India* **5**, 243-8(1939).—A general survey. C. J. West

The action of alkylmagnesium halides on coumarin and related compounds. Synthesis of 2,2-dialkyl-1,2-benzopyrans. R. L. Shriner and A. G. Sharp. *J Org. Chem.* **4**, 575-82(1939).—Insecticides such as deguelin (I) are characterized by the presence of a dihydrobenzopyran ring system (AB) and a dimethylbenzopyran system (DE). To study whether portions of this mol. would possess insecticidal activity, a series of 2,2-dialkyl-1,2-benzopyrans (II) is prepd. by the method of Houben (*Ber.* **37**, 489(1904)) by treating coumarin (III) with an excess of alkylmagnesium halide. Since the Grignard reagent may react with the conjugated system in III to give either 1,2- or 1,4-addn. products, it is necessary to establish the structure of the reaction products. The mol. refractivities indicate that the double bond of the pyran ring is conjugated with the C_6H_6 ring. This is further proved by the

(I)

formation of *o*-HOC_6H_4CHO (IV) on ozonolysis and of *2,2-dimethylchroman* (V) on catalytic reduction. According to H., in the reaction the lactone ring of III is opened and closed again. If this is correct, addn. of MeMgI either to III or to *o-hydroxybenzalacetone* (VI) should give the same product. Decompn. of the addn. compd. of VI gives *4-(o-hydroxyphenyl)-2-pentanone* (VII) which, when heated to its m. p., loses H_2O and by ring closure forms *2,4-dimethyl-1,2-benzopyran* (VIII). Ozonolysis of VIII gives *o*-hydroxyacetophenone. This indicates that the reaction mechanism as proposed by H. is incorrect. Heilbron and Hill (*C. A.* **21**, 3613) also assumed a rupture of the ring in III which would lead to a 1,4- addn. When an excess of Grignard reagent is added to III an oxonium type of intermediate is formed as a very transitory yellow ppt. (cf. Decker and Fellenberg, *C. A.* **2**, 98) while when a mol. amt. is added a yellowish pasty ppt. is formed which on hydrolysis with NH_4Cl regenerates III. It is suggested that the formation of II probably involves an intermediate coordination compd. (IX) in which the alkyl group undergoes an α,γ-shift. Subsequent reaction with a 2nd mol. of

(IX)

Grignard reagent gives II. Since III is a lactone of *cis-o*-$HOC_6H_4CH{:}CHCO_2H$ it was of interest to study the behavior of the trans deriv. toward MeMgI. In this reaction VI is formed which is identical with the compd. obtained on condensation of IV with Me_2CO. VI is therefore the trans form. Stereochem. considerations therefore play a rôle in detg. the mode of action of the Grignard reagent on conjugated systems. In general, II are prepd. by addn. of 0.125 mol. III in 200 cc. Et_2O to a Grignard soln. prepd. from 0.41 mol. Mg and 0.4 mol. alkyl halide in 150-175 cc. Et_2O over a period of 2-4 hrs. The mixt. is decompd. with 200 cc. of a 22% NH_4Cl soln. contg. 2-5 cc. concd. HCl. The Et_2O soln. is dried with $CaCl_2$, evapd. and the residue distd. The following II are prepd.: *Me deriv.* (X), $b_{2.5}$ 79-80°, n_D^{25} 1.5490, d_4^{20} 1.0163; *Et deriv.*, $b_{2.8}$ 99-100°, n_D^{25} 1.5428, d_4^{20} 1.0049; *Pr deriv.*, $b_{2.8}$ 118-20°, n_D^{25} 1.5320, d_4^{20} 0.9773; *Bu deriv.*, $b_{2.8}$ 138-40°, n_D^{25} 1.5257, d_4^{20} 0.9656; *Am deriv.*, b_8 156-8°, n_D^{25} 1.5184, d_4^{20} 0.948; C_6H_{13} *deriv.*, b_8 174-6°, n_D^{25} 1.5136, d_4^{20} 0.9351; C_7H_{15} *deriv.*, b_8 192-3°, n_D^{25} 1.5095, d_4^{20} 0.9233. A soln. of X turns reddish on standing; it reduces $KMnO_4$ and decolorizes Br. It is stable toward boiling alc. alkali (cf. Heyes and Robertson, *C. A.* **29**, 5111[2]). X dissolves in concd. H_2SO_4 with a deep-red color. Boiling with AcOH causes no isomerization (cf. Löwenbein, *C. A.* **19**, 286). Hydrogenation of 12 g. X in 100 cc. EtOH with PtO_2 yields V, b_2 67.5-8°, n_D^{25} 1.5264, d_4^{20} 1.0237, in 92% yield. Ozonization of 5 g. X in 30 cc. CCl_4, decompn. with 50 cc. H_2O, 1 g. Zn, 1 cc. AcOH and 0.2 g. *p*-$C_6H_4(OH)_2$ gives IV, identified as the *2,4-dinitrophenylhydrazone*, m. 250.5-1°. No other decompn. product can be isolated. VI (0.046 mol.), prepd. according to Harries (*Ber.* **24**, 3180(1891)), when treated with 0.1 mol. MeMgI and the addn. compd. decompd., gives VII, m. 127-9° with dehydration. Its *semicarbazone* m. 155-5.5°. When

VII is heated for 10 min. at its m. p. VIII, b_3 79–80°, n_D^{25} 1.5428, d_{20}^{20} 1.0196, is formed. Ozonization of VIII gives *o-hydroxyacetophenone*, b. 215–20°; its *semicarbazone* m. 205–7° (cf. Pauly and Lockemann, *C. A.* **9**, 1052). When 0.06 mol. *trans-o*-hydroxycinnamic acid prepd. according to Dodge (*C. A.* **10**, 764) is treated with 0.36 mol. MeMgI and the addn. compd. decompd. with NH_4Cl soln. VI, m. 136–8°, is obtained in 15% yield. X causes paralysis of a goldfish in 3 min. whereas VIII requires 15 min. The higher II have no effect. F. E. Brauns

Constitutents of some Indian essential oils. XXVI. The structures of *l*-α- and -β-curcumenes. F. D. Carter, F. C. Copp, B. Sanjiva Rao, J. L. Simmonsen and K. S. Subramaniam. *J. Chem. Soc.* **1939**, 1504–9; cf. *C. A.* **23**, 149.—*l*-α-Curcumene (I) (*loc. cit.*), present in the essential oil from the rhizomes of *Curcuma aromatica*, regenerated from the HCl salt (II), b_{17} 137°, d_{20}^{20} 0.8821, n_D^{20} 1.4989, α_{5461} −34.3°; titration with perphthalic acid in $CHCl_3$ indicates 1 double bond, as does catalytic reduction with Pd-norite in EtOH. Heating I with Se at 250° for 6 hrs. and at 280–310° for a further 8 hrs. gives a deep-blue oil, b_6 150–70°, which yields a black picrate, m. 120°, identical with that from the azulene (III) from the original oil; under similar conditions II gives III and cadalene (picrate, m. 115°). The *nitrosate* of I m. 101°, $[\alpha]_{5461}$ −20.3° ($CHCl_3$, *c* 6.005). *l*-Dihydro-α-curcumenylamine, b_{14} 153–4°; *Ac derv.*, m. 109°; $NaNO_2$ in dil. AcOH gives I. Oxidation of I with MnO_2 gives *p*-toluic, terephthalic and trimellitic acids, sepd. by fractionation of the Me esters. I with O_3 in HCO_2Me gives a mixt. of HCHO, Me_2CO, *l-Me* γ-*p-tolylpentyl ketone* (IV), b_{15} 154°, d_{20}^{20} 0.9451, n_D^{20} 1.5016, α_{5461} −30.8° (*semicarbazone*, m. 138–9°), γ-*p-tolylvaleraldehyde* (V), isolated as the *2,4-dinitrophenylhydrazone*, golden, m. 94–5°, and *l*-γ-*p-tolylvaleric acid* (VI), b_{17} 180°, $[\alpha]_{5461}$ −13.82° (EtOH, *c* 13.243) (*p-phenylphenacyl ester*, m. 73–4°); oxidation of VI with alk. $KMnO_4$ gives *p*-MeC_6H_4Ac. Details are given of the sepn. of these products. Me_2CO, V and VI result from *l*-ζ-*p*-tolyl-β-methyl-Δβ-heptene (VII). *p*-MeC_6H_4CH-$MeCH_2CH_2CH.CMe_2$, HCHO and IV result from *l*-ζ-*p*-tolyl-β-methyl-Δα-heptene, *p*-$MeC_6H_4CHMeCH_2CH_2$-$CH_2CMe{:}CH_2$ (VIII). Comparative expts. on the ozonolysis of I regenerated from II and of the original mixt. of hydrocarbons as isolated by distn. indicate that, whereas the former consists of approx. equal quantities of VII and VIII, in the natural hydrocarbon VII predominated. The acidic fraction on esterification, followed by sapon. of the fraction b_{23} 100–45° and oxidation of the acid with NaOBr yields α-methylglutaric acid and some succinic acid. *l*-β-Curcumene (IX), regenerated from the tri-HCl salt, b_{19} 142°, d_{25}^{25} 0.8670, n_D^{25} 1.491, α_{5461} −48.2°; on catalytic reduction 2 double bonds react rapidly (2 hrs.), whereas the 3rd requires 15 hrs.; IX with CrO_3 yields terephthalic acid. The action of O_3 showed that IX was not homogeneous, the products being HCHO, Me_2CO, a *diketone*, $AcCHMeCH_2CH_2CH_2Ac$ (whose *2,4-dinitrophenylhydrazone*, orange, m. 178–80°), some Me levulinate, and the degradation products of I. I is not attacked by SeO_2 in EtOH at 40–50°; IX gives a mixt. of X and *l*-β-*curcumenol*, b_{17} 175°, d_{20}^{20} 0.9563, n_D^{20} 1.5164, α_D 39°, isolated as the liquid H phthalate; the *p-xenylurethan* m. 79–80°; oxidation gives X. *l*-β-Curcumenal (X), b_{17} 175°, d_{20}^{20} 0.9644, n_D^{20} 1.5331, α_{5461} −74.1°, was isolated as the *semicarbazone* (XI), m. 199°, $[\alpha]_D$ −77.8° ($CHCl_3$, *c* 4.5); 3.9 g. of XI gives only 8 g. X. X is somewhat unstable and after digestion with H_2O no longer gives cryst. derivs.; the *2,4-dinitrophenylhydrazone*, orange, m. 139°, $[\alpha]_D$ −145.4° ($CHCl_3$, *c* 3.4); *nitroguanylhydrazine*, m. 151°, $[\alpha]_D$ −86.1° ($CHCl_3$, *c* 3.1); *oxime* (XII), b_4 170–5°, d_{20}^{20} 0.9851, n_D^{20} 1.5324, α_D −67°. Heating XII with Ac_2O or AcONa for 2 hrs. on the water bath gives *β-curcumenonitrile*, b_{17} 178–82°. EtOH and KOH (48 hrs.) give β-curcumenylic acid, whose *Me ester* b_{16} 180–2°; *anilide*, m. 87°. IX is believed to be $CH_2.CR.CH.CH_2.$-$CMe{:}CH$, where R is $CHMeCH_2CH_2CH_2CMe{:}CH_2$ or $CHMeCH_2CH_2CH_2{:}CMe_2$. C. J. West

Phellandrene nitrosites. II. The α- and the β-nitrosite of *d*-α-phellandrene. P. A. Berry, A. Killen Macbeth and T. B. Swanson. *J. Chem. Soc.* **1939**, 1418–21; cf. *C. A.* **33**, 4222⁸.—*d*-α-Phellandrene (I), b_{11} 53°, n_D^{20} 1.4729, d_{20}^{20} 0.8475, α_D 72.5°, $[\alpha]_D^{20}$ 85.5°, was used in this study. I was transformed into the nitrosite (II) as in part I. After 1 hr. it was filtered, washed with EtOH and H_2O, pressed and stirred with CS_2 to a thin cream, boiled and filtered. Crude β-II was recovered from the filtrate by diln. with MeOH. The residue was stirred into boiling $CHCl_3$ and after addn. of MeOH was allowed to stand in the refrigerator for a few hrs. (ppt. A). The filtrate gives β-II, m. 100°, $[\alpha]_D^{20}$ 198.3° ($CHCl_3$, *c* 1.5). Repeated soln. of ppt. A in $CHCl_3$ and diln. with MeOH gives α-II, m. 117°, $[\alpha]_D^{20}$ −133.8° ($CHCl_3$, *c* 1.265), −168.4° (Me_2CO, *c* 1.253), −217° (C_6H_6, *c* 1.255). Refluxing β-II in Me_2CO for 5 min. gives α-II. The mutarotation of α- and β-II in C_6H_6, Me_2CO, $CHCl_3$ and 0.1 *N* piperidine in $CHCl_3$ is reported, some curves being given. C. J. West

Synthetic investigations in bicyclic terpenes. P. C. Guha. *Proc. Natl. Inst. Sci. India* **5**, 217–33(1939).—A review of syntheses in the pinane (ketonopinone), pinocamphone, pinic acid, pinonic acid, nopinone), thujane, carane and camphane groups. C. J. West

The stereochemistry of pinane and its derivatives. K. Ganapati. *J. Indian Inst. Sci.* **22A**, 155–69(1939).—A discussion of the isomerism of pinane and related compds. in the light of the Sachse-Mohr theory, and of the bearing of this isomerism and of ring strain upon the chem. properties. G. R. Yohe

The action of acetic acid on camphene in the presence of boroacetic acid anhydride or acetic anhydride and boric trioxide. Minoru Imoto. *J. Soc. Chem. Ind., Japan* **42**, Suppl. Binding 267–8(1939); cf. *C. A.* **33**, 8593⁸.—Equil. at 110–20° for camphene + acetic acid ⇌ isoborneol acetate occurs when approx. 67–69% of ester is present, the equil. concns. being approached from each side, with $B(OAc)_3$ or Ac_2O and B_2O_3 as catalyst. From camphene with $[\alpha]_D^{15}$ 5.47° in alc., the ester was obtained with $[\alpha]_D^{15}$ varying from −1.87° to −9.60°, from which, on sapon., isoborneol was obtained with $[\alpha]_D^{15}$ varying from ± 0° to −0.59° (in alc.). Addn. of H_2SO_4 to the reaction system at 50–60° increases the yield of ester. Thus 136 g. camphene, 120 g. of 99% HOAc, 20 g. Ac_2O and 1.9 g. B_2O_3 at 110–20° for 14 hrs. gave 63% ester; further addn. of 12 g. of 80% H_2SO_4 to the reaction mixt. at 50–60° for 3 hrs. resulted in a 95.2% total yield of ester. George Ayers

Thujone series. III. Chemistry of sabina ketone. Andrew G. Short and John Read. *J. Chem. Soc.* **1939**, 1415–18; cf. *C. A.* **33**, 6817².—Oil of savin (150 g.) gives 45 g. *d*-sabinene (I); oxidation of 25 g. I with alk. $KMnO_4$ gives 40 g. Na sabinenate; further oxidation with acid $KMnO_4$ gives 65% of sabina ketone (II); pure *l*-II from the oxidation of III, b_{11} 97.5°, n_D^{25} 1.4672, d_4^{25} 0.9195, $\alpha_D^{15.6}$ −19.8°, $[\alpha]_D^{15}$ −34.2° (EtOH, *c* 2), $[R_L]_D$ 40.38 (calcd. 39.51); *semicarbazone*, amorphous, m. 135–7°, $[\alpha]_D^{15}$ 137.5° (MeOH, *c* 1); *2,4-dinitrophenylhydrazone*, orange, m. 124.5°, $[\alpha]_D^{15}$ 135.2° ($CHCl_3$, *c* 1). The rotatory power of II is not appreciably affected by EtOH-EtONa; hot aq.-alc. H_2SO_4 gives 4-isopropyl-2-cyclohexen-1-one. II is incompletely reduced by (iso-PrO)$_3$Al in iso-PrOH; Na in EtOH gives a mixt. of *sabina ketols* (III); crystn. of the *p*-nitrobenzoate from MeOH gives the pure *ester*, m. 89.5°, α_D^{15} 94.5° ($CHCl_3$, *c* 1), of *d*-α-III, b_{16} 100°, d_4^{25} 0.9397, n_D^{25} 1.4670, α_D^{15} 80.84°, $[\alpha]_D^{15}$ 90.6° (EtOH, *c* 1.2), $[R_L]_D$ 41.36 (calcd. 40.85); *3,5-dinitrobenzoate*, m. 70.5°, $[\alpha]_D^{20}$ 81.5° ($CHCl_3$, *c* 6). Catalytic reduction of II gives a product with more of β-III but it could not be isolated pure. Heating II with HCO_2NH_4 at 200° for 3 hrs. gives a mixt. of α- and β-*sabinaketylamines*, $b_{19.5}$ 63–4°, n_D^{20} 1.4705, α_D^{15} 43.8°; crystn. from MeOH gives a *p-nitrobenzoate*, m. 141°, α_D^{15} 84° ($CHCl_3$, *c* 1); *HCl salt*, m. 225° (decompn.), $[\alpha]_D^{15}$ 36.1° (H_2O, *c* 0.8); the portion nonvolatile with steam may be disabinaketylamine, $b_{9.6}$ 166–7°, $n_D^{15.6}$ 1.4987, $[\alpha]_D^{15}$ 60.6° ($CHCl_3$, *c* 1.2). II may be regarded

as a link between 2 important natural groups of substances, of which the thujones and the phellandrenes, severally, are representatives. C. J. West

Reactions of α,β-unsaturated cyclic aldehydes and ketones. V. *dl*-Cryptone and *cis*- and *trans-dl*-cryptol. D. T. C. Gillespie and A. Killen Macbeth. *J. Chem. Soc.* **1939**, 1531–4; cf. *C. A.* **33**, 3360².—*l*-Cryptone (200 g.), α_D −61°, 200 cc. Et_2O and 10 g. concd. HCl, heated for 1.5 hrs. and the HCl removed by 1% Na_2CO_3, give 87% of *dl*-cryptone (I), $b_{2.8}$ 78°, n_D^{25} 1.4810, d_{20}^{20} 0.9393; *semicarbazone*, m. 188°; *p-nitrophenylhydrazone*, yellow, m. 169–1°; *2,4-dinitrophenylhydrazone*, deep orange-red, m. 130–1°. Reduction of I with $(iso\text{-}PrO)_3Al$ in iso-PrOH gives 88% of crude *trans-dl*-cryptol (II), purified through the *p-nitrobenzoate* (III), pale yellow, m. 76.5°, II b_4 90°, n_D^{25} 1.4761, d_{20}^{20} 0.9247; the configuration of II follows from its reduction to the dihydro deriv. (α-naphthylurethan, m. 157.8°). II yields an *α-naphthylurethan*, m. 136°, and a *phenylurethan*, m. 108°. The *H phthalate* m. 97–7.5° and the *3,5-dinitrobenzoate* m. 106° (*α-naphthylamine salt*, orange, m. 140°). The mother liquor from III contains *cis-dl*-cryptol (IV), which was isolated in small yield by the tedious fractionation of the α-$C_{10}H_7NH_2$ salt of the 3,5-dinitrobenzoate. IV b_6 86°, n_D^{25} 1.4752, d_{20}^{20} 0.9282; *3,5-dinitrobenzoate*, m. 96.5° (*α-naphthylamine salt*, deep orange-red, m. 102–4°); reduction gives the dihydro deriv. (α-naphthylurethan, m. 112–13°). IV yields an *α-naphthylurethan*, m. 105.5°; the *p-nitrobenzoate* m. 34.5–5.5°. Iso-PrOH for Pondorf reduction is kept over quicklime and before use it is refluxed with Ca for 2 hrs., distd. into a flask contg. some $(iso\text{-}PrO)_3Al$ and then into a perfectly dry receiver. This iso-PrOH dissolves Al foil (dusted with a little $HgCl_2$) on refluxing for 20–30 min. C. J. West

Constituents of Herba gratiola officinalis (hedge hyssop). I. Kurt Maurer, Karl Meier and Georg Reiff.* *Ber.* **72B**, 1870–3(1939); cf. Retzlaff, *Arch. Pharm.* **240**, 561(1902).—Retzlaff's gratiolone (I) has been prepd. in pure form and the glucoside, gratiolin, has been isolated and its glucosidic nature confirmed. Extn. of 2 kg. of the powd. drug gave 14 g. ext. which, after exhaustive extn. with petr. ether and repeated crystn. of the residue from MeOH with animal charcoal, yielded 5 g. I, $C_{30}H_{48}O_3$, m. 311–12°, sublimes at 240–60° under 15 mm., mol. wt. 454–6 (Rast), 452–7 (titration in MeOH with alc. KOH), $[\alpha]_D^{25}$ 5.7° (pyridine). Two of its O atoms are in a CO_2H group; the alkali salts have a great tendency to gelatinize and their solns. accordingly foam strongly. The 3rd O atom is in an alc. grouping; I can be acetylated under the most varied conditions, forming a cryst. *acetate*, m. 268°, $[\alpha]_D^{25}$ 20.4° ($CHCl_3$). *Me ester*, prepd. with CH_2N_2 in ether, m. 220°, $[\alpha]_D^{25}$ 5.0° ($CHCl_3$), forms an *acetate*, m. 197°. I is therefore a *hydroxycarboxylic acid*, $C_{29}H_{46}(OH)$-CO_2H, apparently of the triterpene group. With $C(NO_2)_4$ in $CHCl_3$ it gives an intense-yellow color and on titration with BzO_2H it uses up exactly 1 atom O. In CCl_4 it absorbs 1 mol. Br with liberation of HBr; the cryst. *product*, $C_{30}H_{47}O_3Br$, m. 257°, is a bromo lactone; it no longer shows acid properties, regenerates I with Zn dust in boiling acetone and no longer gives a color with $C(NO_2)_4$ but still contains the HO grouping, for it forms an *acetate*, m. 186°, $[\alpha]_D^{25}$ 12.5° ($CHCl_3$); alc. KOH hydrolyzes it to a Br-free *compd.*, m. 239° (decompn.), and CrO_3-AcOH oxidizes it to the *ketone*, m. 232°, characterized as the *oxime*, C_{30}-$H_{46}O_3NBr$, m. 188°, $[\alpha]_D^{25}$ −5.5° ($CHCl_3$). C. A. R.

Question of intramolecular asymmetric induction. Alex. McKenzie and Alex. D. Wood. *J. Chem. Soc.* **1939**, 1536–44.—Kuhn and Albrecht (*C. A.* **21**, 2892) found that the quinine salt of 4,4′-dinitrodiphenic acid (I) results in 80% yield and that it is strongly *d*-rotatory, giving $[\alpha]_{5893}$ 108° in $CHCl_3$, whereas quinine itself has $[\alpha]_{5893}$ −177°; the salt was regarded as a homogeneous salt of the activated acid and when the quinine was eliminated from the salt, racemization was supposed to take place owing to the removal of groups which acted as obstacles to the free rotation of the C_6H_6 nuclei. From the following study it is seen that the esters were all *l*-rotatory in the solvents chosen and that there was no evidence that intramol. asym. induction of I had occurred under the directing influence of the optically active menthyl and bornyl groups. The conclusion is drawn that Kuhn's suggestion of "asym. rearrangement of the 1st order" with I under the influence of quinine must remain an open question in the meantime. I (10 g.) and (−)-menthol, heated at 130° for 13 hrs., HCl being passed in at intervals, give 4 g. of the (−)-*monomenthyl ester* (II), amorphous, m. 166–7°, and a small quantity of the (−)-dimenthyl ester (III), amorphous, m. 61–2°. On heating 27 hrs., 11 g. I gives 5.7 g. of II and 3.1 g. of III; III also results from the chloride of I or II and (−)-menthol. Values are given for $[\alpha]_D^{25}$ and $[\alpha]_{5461}^{20}$: I −55.8°, −63° (EtOH, *c* 1.04); −58.4°, −64.3° ($CHCl_3$, *c* 0.6768); −59.4°, −65.2° (C_6H_6, *c* 0.598). II —, −89.8° (EtOH, *c* 0.8964); −74°, —(EtOH, *c* 0.5676); −78.3°, −95.4° ($CHCl_3$, *c* 0.734); −83.6°, −96.3° (C_6H_6, *c* 0.8868). (−)-Menthyl *m*-nitrobenzoate, −81.3°, −95.2° (EtOH, *c* 1.4024); −83.7°, −99.2° ($CHCl_3$, *c* 1.5224); −86.7°, −101.4° (C_6H_6, *c* 2.0815). (−)-Dimenthyl phthalate, −96.9°, −119.0° (EtOH, *c* 0.5212); −95.4°, −113.8° ($CHCl_3$, *c* 1.6032); −95.9°, −(C_6H_6, *c* 1.9815). I (16 g.) and (−)-borneol, heated 18 hrs. at 165–75°, give 10.9 g. of (−)-*dibornyl ester* (IV), m. 201–2°, −40°, −48.1° (Me_2CO, *c* 1.434); −46.9°, −56.3° (EtOH, *c* 0.2132); −41.5°, −48° ($CHCl_3$, *c* 1); −32.8°, −41.3° (C_6H_6, 0.533). Partial sapon. of IV with KOH in aq. EtOH gives (−)-*monobornyl ester* (V), amorphous, m. 178–9°, −28.9°, −33.8° ($CHCl_3$, *c* 2.1292); −25°, −29.6° (C_6H_6, *c* 1.62). (−)-*Bornyl m-nitrobenzoate*, m. 76–7°, −36.1°, −43.2° (EtOH, *c* 0.7284); −36.9°, −42.5° ($CHCl_3$, *c* 1.2475); −32.7°, −(C_6H_6, *c* 2.0045). (−)-Dibornyl phthalate, m. 104–5°, −82.9°, −97.1° (EtOH, *c* 0.4582); −67.8°, −80.8° ($CHCl_3$, *c* 2); −64.5°, −(C_6H_6, *c* 2.1695). I and cinchonine in EtOH, heated 1 hr., give the cinchonidine salt, m. 220–1°, $[\alpha]_{5461}^{20}$ −185.6° ($CHCl_3$, *c* 4.025). The quinidine salt of I has $[\alpha]_D^{25.5}$ −87° ($CHCl_3$, *c* 2.1325). The acid quinine salt of I m. 195–6°, $[\alpha]_D^{25.7}$ 46.6°, $[\alpha]_{5461}^{20}$ 55.5° (EtOH-$CHCl_3$, *c* 1.0185); there is no evidence of mutarotation in 10 days. I (8 g.) and 18.4 g. of quinine in 360 cc. EtOH give 21.6 g. of a salt, m. 229–31° (decompn.), $[\alpha]_D^{25}$ 102.4°, $[\alpha]_{5461}^{21}$ 119.6° ($CHCl_3$, *c* 1.998); crystn. 3 times from C_6H_6 gives $[\alpha]_D^{25}$ 85.2° ($CHCl_3$, *c* 2.001); the mother liquor gives 1.5 g. of a salt m. 226–7°, (decompn.), $[\alpha]_D^{25}$ 108.5°, $[\alpha]_{5461}^{20}$ 128.5° ($CHCl_3$, *c* 2.0084); on recrystn. from C_6H_6-$CHCl_3$ the salt seps. with 2 moles of C_6H_6; the rotation of the dried salt is $[\alpha]_D^{25}$ 101° ($CHCl_3$, *c* 3.02). V with $SOCl_2$ gives the *acid chloride*, m. 48–9°; with (+)-borneol there results (+)-*bornyl*(−)-*bornyl 4,4′-dinitrodiphenate*, m. 212–13°; the *dl*-dibornyl ester of I m. 200–1°. C. J. West

Certain therapeutically important triphenylmethane dyestuffs. Mieczysław Dominikiewicz. *Arch. Chem. Farm.* **4**, 58–68(in German, 68)(1939).—Syntheses of several triphenylmethane dyestuffs from guaiacol and vanillin, guetol (Et analog of guaiacol) and bourbonal (Et analog of vanillin), guaiacol and bourbonal, as well as guetol and vanillin, are described. By condensation of the above-named constituents the corresponding triphenylmethanes or fuchsones (dyestuffs) are formed. By reduction of the dyestuffs, triphenylmethanes are formed, and vice versa, by oxidation of the latter the dyestuffs are obtained. From guaiacol and vanillin the following compds. were synthesized: triguaiacylmethane, [4,3-HO(MeO)C_6H_3]$_3$CH (I), brick-red or orange amorphous ppt., m. 88–90°, sol. in alkalies as well as in EtOH and in EtOAc, almost insol. in Et_2O; triguaiacylmethyl chloride (II), a water-sol. compd. of brown-red color, with a metallic luster, m. 198–201° (decompn.); and triguaiacylcarbinol (III), brown-red crystals from EtOAc, m. about 235°, which on soln. in NaOH forms the dyestuff (fuchsone) proper, [HO(MeO)C_6H_3]$_2$C·C_6H_3(OMe):O (IV). IV has been introduced recently (under the trade name Rubofrene) as a remedy for skin and bone tuberculosis; it is used in the form of the dyestuff proper or in the form of its additive compd. (V) with Na_2SO_3, which also was synthesized. V is perfectly sol. in water with a slightly

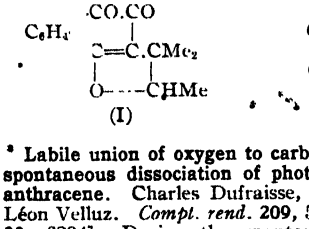
orange color, which gradually changes to red. In a series of syntheses and transformations, similar to those above mentioned, the following compds. were obtained: from bourbonal and guetol, triguetylmethane, [4,3-HO(EtO)-$C_6H_3]_3CH$ (VI), and the corresponding carbinol; from guaiacol and bourbonal, diguaiacylguetylmethane, [HO-(MeO)$C_6H_3]_2CHC_6H_3$(OEt)OH, (VII) and the corresponding carbinol; from guetol and vanillin, diguetylguaiacylmethane (VIII) and the corresponding carbinol. All these compds. have very similar properties and their therapeutic effects are probably also very similar. E. A. A.

Thio compounds derived from *o*-aroylbenzoic acids. John O'Brochta and Alexander Lowy. *J. Am. Chem. Soc.* **61**, 2765-8(1939).—*o*-$BzC_6H_4CO_2H$ (I) (20 g.) and 20 g. P_2S_5 in 700 cc. C_6H_6, refluxed 25 hrs., give 11 g. of *3,3'-diphenyldiphthalidyl sulfide* (II), m. 241°; II also results in 5-g. yield by heating 10 g. I and 10 g. P_2S_5 at 115° for 1 hr. and in 60-g. yield from the chloride from 100 g. I in 400 cc. C_6H_6 by passing H_2S through the boiling soln. until evolution of HCl ceases. NaOH fission of II gives a pos. test for S^{++}; refluxing with 5% EtOH-KOH gives I, the S being eliminated as H_2S. H_2SO_4 gives anthraquinone. Oxidation with CrO_3 or HNO_3 gives I and 30% H_2O_2 gives I and phenylphthalide (III); boiling with $Pb(OAc)_4$ gives PbS and I; reactions with $PhNH_2$, PhOH and $PhNHNH_2$ yield compds. obtained from I and these reagents. Refluxing II and Cu dust in cymene for 3 hrs. gives 3,3'-diphenylbiphthalidyl. With $AlCl_3$ in C_6H_6 II gives *thiodiphenylphthalide*, m. 162°, III being recovered from the mother liquors. P_2S_5 gives dithiodi(phenylphthalide). Addn. of 50 g. P_2S_5 to 50 g. I in boiling xylene and refluxing 4 hrs. gives, after a complex purification, 7 g. of *2-phenyl-3,4-benzothiophene* (IV), reddish brown, m. 236–7°, which is not hydrolyzed by EtOH-NaOH and is unchanged by heating with Cu in Ph_2 or by Na or HgO in xylene. *o*-(*p*-$MeC_6H_4CO)C_6H_4CO_2H$ gives 30% of *3,3'-di(p-tolyl)diphthalidyl sulfide*, m. 212°; the acid chloride and H_2S give 60%; *(p-chlorophenyl)analog*, m. 232°, 40% with P_2S_5 or 68% with the acid chloride and H_2S. *p-Tolyl analog* of IV, m. 217°, 28%; *p-chlorophenyl analog*, m. 241–2°, 12%. *p-Chlorophenylphthalide*, m. 124°, 50% yield. C. J. West

Reactive methylene groups and nitroso compounds. Abnormal action of acids on 1,2,3-triketones. Alexander Schönberg and Raymond C. Azzam. *J. Chem. Soc.* **1939**, 1428-30; cf. *C. A.* **31**, 4286[6].—Further examples of the formation of anil oxides by the action of PhNO and its derivs. on methylene ketones are reported. The substance hitherto known as $PhC(:NC_6H_4NMe_2)Bz$ is in fact the corresponding *anil oxide* (I). Desoxybenzoin (4 g.) and *p*-$ONC_6H_4NMe_2$ (II) in abs. EtOH and piperidine, heated 3 hrs. on the steam bath and kept 24 hrs. at 0°, give 3.6 g. of I, red, m. 165–6°, and *benzil-p-dimethylaminoanil* (III), orange-red, m. 137–8°. Hydrolysis of I or III with H_2SO_4 in AcOH gives benzil (IV). CH_2Br_2 (V) (3.4 g.) and PhNO in abs. EtOH, heated 20–30 min. on the steam bath, give 2.2 g. of *diphenyl triketone β-anil oxide*, yellow, m. 144–5° (decompn.); hydrolysis with H_2SO_4 gives IV. V and II give the *β-p-dimethylaminoanil oxide*, dark red, m. 183–5° (decompn.). *p*-$MeC_6H_4CO-CH_2Bz$ and PhNO give *1'h p-tolyl triketone β-anil oxide*, light yellow, m. 141–3° (from C_6H_6), or canary-yellow needles, m. 132–4° (from petr. ether). $COBr_2$ and H_3PO_4 in AcOH give benzoin (VI); H_2SO_4 gives IV; VI with H_2SO_4 is oxidized to IV. Bz_2CO and $AlCl_3$, heated 1 hr. at 100°, also give IV. Triketohydrindene hydrate(ninhydrin) and concd. H_2SO_4 give bisindandione. C. J. West

Evidence for a skew structure of benzil. C. C. Caldwell and R. J. W. Le Fèvre. *J. Chem. Soc.* **1939**, 1614–22; cf. *C. A.* **33**, 5248[1].—The suggestion is made that the stable configuration of benzil (I) in nonpolar solvents is 1 in which the ketonic groups, with their appropriate bonds, are effectively situated in, or make rotational oscillations of low amplitude about, 2 planes which are roughly mutually perpendicular. The evidence consists in the value of the dipole moment of I, the fact that this shows no greater dependence upon solvent than does the corresponding value for phenanthraquinone (II) and the observations that the moment is const. throughout a temp. range of 65° in decalin or 25° in C_6H_6 or CCl_4. Other explanations of these data are discussed and rejected. Such a *skew* structure could arise if the dominant forces setting the shape of the mole were superimposed dipolar repulsions between the C.O moments and steric repulsions between the Ph groups and O atoms (tending to a trans-cis structure). Compatibly with such a view Ac_2 (in which dipolar repulsions should be much the same as, but the van der Waals attractions weaker than, in I) appears to be either much more flexible or more trans in type. The following values are given: for I, hexane 3.4_9, decalin 3.3_3, dioxane 3.7_8, CCl_4 3.6_0, C_6H_6 3.7_8, CS_2 3.4_4, $CHCl_3$ 3.2_1; for II, dioxane 5.66, C_6H_6 5.5_7, CS_2 5.5_0, $CHCl_3$ 4.7_1; for acenaphthaquinone in C_6H_6 6.0_8. Values for I in decalin: 25° 3.33, 50° 3.31, 70° 3.34, 90° 3.3_4; in C_6H_6 at 25° 3.76, 50° 3.6_8. Ac_2 in C_6H_6 1.84. C. J. West

1,5-Dimethylnaphthalene in coal tar. Otto Kruber and Alfred Marx. *Ber.* **72B**, 1970–1(1939).—There had thus far been isolated from the 260–70° fraction of coal-tar heavy oil 1,6-, 2,6-, 2,7-, 2,3-, 1,2- and 1,7-dimethylnaphthalenes (*C. A.* **30**, 6535[5], and earlier papers). A 7th of the 10 possible isomers, viz., the 1,5-di-Me compd. (I), has now been obtained. It always accompanies the 2,3-isomer (II), which it greatly resembles. II is obtained by chilling appropriate fractions of the heavy oil. Some of these well-chilled, entirely liquid fractions were fractionally sulfonated. From the first and middle sulfonation fractions considerable amts. of the 1,6- and 1,7-isomers of I were obtained. The last sulfone acids, which could no longer be made to crystallize, were salted out with KCl and the K salts, after crystn. from water, were decompd. with superheated steam. In this way I was obtained as needles from alc., m. 82°, b_{761} 265–5.5° (picrate, golden yellow, m. 140°); yield, 25 g. from 7 kg. of a heavy-oil neutral fraction, b. 265 8°, which had to a great extent been freed from II by repeated fractionation and chilling and was then washed with 1 kg. of 92% H_2SO_4 to remove the acenaphthene and fractionally sulfonated with 1-kg. portions of $H_2SO_4.H_2O$ at 45°. The oil which remained unsulfonated (about 4%) was stable even toward oleum (15% SO_3). It had a pronounced paraffin odor and a markedly higher b. p. (281–7°) than the original material and showed d_{15} 0.836, n_D^{25} 1.46702, C 86.15%, H 13.93%. C. A. R.



The trimethylnaphthalenes in coal tar. Otto Kruber. *Ber.* **72B**, 1972–7(1939).- The 280-90° fraction of coal-tar heavy oil on cooling to room temp. deposits considerable amts. of "mixed crystals" consisting chiefly of acenaphthene, diphenylene oxide and fluorene (*C. A.* **26**, 5936). Further fractionation and chilling of the oily portion gives more mixed crystals until finally there remains 1/4 or 1/6 of the original material as a "true oil," b. 280–90°. In this oil there has been found a class of compds. entirely new in coal tar, viz., trimethylnaphthalenes, consisting of a mixt. of solids and liquids which, when together, remain liquid when chilled. Of the 14 possible isomers, 2 have been identified and isolated in pure form: the 2,3,6- (I) and the 1,3,7-isomer (II). The total trimethylnaphthalenes constitute hardly more than 0.1% of the coal tar but in spite of this they are, in their boiling range, of extraordinary importance from a tech. standpoint as liquefiers of solids, i. e. as new formers of tar oil. The starting material was 3.4 tons of a partially cryst. heavy-oil fraction (representing 1.6% of the total tar), b. 275–95°, contg. 4% acid and 6% basic components. Washing with dil. alkali and acid, centrifugation of the mixed crystals and fractionation of the liquid portion *in vacuo* through a long Raschig column gave 800 kg. of a fraction b. 283–8°, again permeated with crystals, from which, on repeating the process, was obtained 320 kg. of a fraction (III) remaining liquid. The chief impurity which accompanied I and remained in it in considerable amts. even after repeated chilling was diphenylene oxide (IV). To remove it III was heated 3–4 hrs. with an equal wt. of KOH at 270–5°, leaving 260 kg. oil (V) consisting chiefly of trimethylnaphthalenes. V on refractionation gave

about 100 kg. of a fraction, b. 285–91°, which, on standing 12–15 hrs. at −15°, deposited 13.5 kg. crystals; recrystn. from 6 parts alc. yielded 7 kg. I, m. 102°, b_{762} 286°; picrate, m. 130°. Oxidation of I with CrO_3 gave a mixt. of 2,3,6-trimethyl-1,4- and -5,8-naphthoquinones, m. 103° and 72–3°, sepd. by crystn., which with $KMnO_4$ yielded, resp., trimellitic acid, m. 221–3°, and an acid, m. 202–4° (foaming), having the compn., $C_{11}H_{10}O_5$, of *1,2-dimethyl-4,5-phthalonic acid* (from the aq. mother liquor of the latter was isolated pyromellitic acid, m. (anhyd.) 273°). The purification of II was much more difficult. The sulfonic acids of the trimethylnaphthalenes crystallize much more difficultly than those of the di-Me compds. After repeated repptns. of solid deposits from individual sulfonation fractions there were obtained cryst. fractions of quite homogeneous appearance but decompn. with steam almost always gave mixts. of oily isomers with solid I, IV or homologous biphenyls. A 281–5° fraction (6.6 kg.) was sulfonated 9 successive times 4–5 hrs. with stirring at 45° with 750 g. of 92% H_2SO_4 dropped in slowly. The 3rd–9th runs, after standing several days in the cold, deposited solid acids whose Na salts, recrystd. 3 times, gave with superheated steam in the presence of 70% H_2SO_4 335 g. hydrocarbon, from which, through the orange picrate, m. 144°, was obtained 110 g. II, b_{764} 280°, b_{15} 148–50°, d_4^{20} 1.007, n_D^{20} 1.57589, solidifies 13.5°. The Na salt of the sulfonic acid was not reduced by Na-Hg on the water bath; fused with 5 parts KOH and 1 part water, it yielded *1,3,7-trimethyl-6-naphthol*, m. 95–6°, which coupled with PhN_2Cl to a cherry-red *o-hydroxyazo dye*, insol. in cold dil. alkali, and sepg. from AcOEt in dark-red needles, m. 142°. This was reduced in AcOH with $SnCl_2$-HCl to the yellowish white aminonaphthol-HCl which with CrO_3-H_2SO_4 yielded the brownish *1,3,7-trimethyl-5,6-naphthoquinone*, m. 154–5°, oxidized by $KMnO_4$ to 3,5-dimethylphthalic acid, m. 181°. Oxidation of II with CrO_3-AcOH, on the other hand, gave, in small yield (0.2 g. from 2 g. II), the *5,8-quinone*, light yellow needles of penetrating odor, m. 136–7°. All attempts to increase the yield were unsuccessful; the chief product was always a resinous residue (1 g.) remaining after the steam distn. of the ether ext. and sepg. from AcOH in yellowish prisms, m. 183°, mol. wt. 320 (Rast), having the compn. (C 91.86, H 7.63%) of a *hexamethylbinaphthyl*. C. A. R.

The constitution and synthesis of vitamin K_1. E. W. MacCorquodale, L. C. Cheney, S. B. Binkley, W. F. Holcomb, R. W. McKee, Sidney A. Thayer and Edward A. Doisy. *J. Biol. Chem.* **131**, 357-70(1939); cf. *C. A.* **33**, 8602[6], 8718[4].—The constitution of vitamin K_1 as 2-methyl-3-phytyl-1,4-naphthoquinone has been proved by a study of its reactions and degradation products and confirmed by synthesis. Phytyl bromide was condensed with the mono-Na salt of 2-methyl-1,4-naphthoquinone and the vitamin was isolated in the pure condition as the diacetyldihydro deriv. The synthetic compd. gave the same degradation products as the natural vitamin by the same methods. A. P. Lothrop

The isolation of vitamin K_2. R. W. McKee, S. B. Binkley, Sidney A. Thayer, D. W. MacCorquodale and Edward A. Doisy. *J. Biol. Chem.* **131**, 327–44(1939); cf. *C. A.* **33**, 5461[3].—Vitamin K_2 has been isolated in pure form from putrefied com. sardine meal by the use of Decalso and Permutit and by recrystn. from various solvents. Its activity is approx. 600 units per mg. Reductive acetylation converts it to the diacetate of dihydrovitamin K_2 which has a potency 1/2 that of the vitamin. While it is not yet possible to decide definitely upon a formula for the vitamin, the evidence indicates that it is a 2,3-disubstituted 1,4-naphthoquinone with 6 double bonds in the side chains. *Vitamin K_2* m. 53.5–54.5°; *diacetate* of *dihydrovitamin K_2*, m. 59.5–60°. A detailed account of the process of isolation is presented to give other workers sufficient information for prepg. the cryst. vitamin. **The ultraviolet absorption of vitamins K_1, K_2 and some related compounds.** D. T. Ewing, J. M. Vandenbelt and Oliver Kamm. *Ibid.* 345–56.—Ultraviolet absorption studies indicate that vitamins K_1 and K_2 are derivs. of 2,3-dimethylnaphthaquinone and that the side chains do not contain conjugated double bonds. A. P. Lothrop

Dunnione. I. J. R. Price and Robert Robinson. *J. Chem. Soc.* **1939**, 1522–9.—The orange-red deposits on the leaves, stems and flowers of *Streptocarpus dunnii* Mast. yield an orange pigment termed *dunnione* (I). I is extd. with H_2O at room temp. (5–10 times, each for 24–48 hrs.) and removed from the aq. soln. by C_6H_6; the residue is dissolved in EtOH, added to half-satd. $NaHSO_3$, filtered, pptd. with Na_2CO_3, extd. with C_6H_6 and crystd. from petr. ether; 1 leaf yields 0.5–2 g. I. I, $C_{15}H_{14}O_3$, orange-red, m. 98–9°, $[\alpha]_D^{18}$ 310° ($CHCl_3$, *c* 4.163). I is recovered unchanged after heating with concd. H_2SO_4 at 100° for 1 hr. *Semicarbazone*, yellow, m. 232–3°; *2,4-dinitrophenylhydrazone*, orange-red, m. 266–8°. Reduction gives a colorless soln., the color returning on shaking in air; reductive acetylation yields *diacetyldihydrodunnione*, m. 143–4°, $[\alpha]_D^{15}$ 16.7° ($CHCl_3$, *c* 3.236). These reactions suggest an *o*-quinone structure, which is confirmed by the reaction with *o*-$C_6H_4(NH_2)_2$; the *phenazine*, $C_{21}H_{18}ON_2$, yellow, m. 140–1°; the yellow EtOH or Me_2CO soln. has a strong green fluorescence; mineral acid solns. are deep red. I dissolves slowly in cold alkali to a red soln. similar in color to that of lapachol (II) or hydroxyhydrolapachol; the behavior on extn. with org. solvents is the same as that of II; acidification regenerates I. Heating I in lots of 0.2–0.5 g. in 10% NaOH until the red color disappears gives *allodunnione* (III), yellow, m. 161–2°; it is insol. in cold aq. $NaHSO_3$, does not condense with *o*-$C_6H_4(NH_2)_2$ and cannot be acetylated; *2,4-dinitrophenylhydrazone*, yellow-orange, m. 315° (decompn.). On keeping I with 5% NaOH at room temp. for 2 days, a part forms a red soln. and a part changes to a yellow solid; shaking with C_6H_6, washing with 1% HCl and crystn. from petr. ether yields *α-dunnione* (IV), yellow, m. 121–2°; the alk. liquor contains III. IV also results by heating I with 20% HCl for 2 hrs.; I is unchanged on heating with HBr (d. 1.49) for 1 hr. at 70°. IV gives a brilliant-red soln. in concd. H_2SO_4 and is recovered unchanged after 2 hrs. at room temp. Boiling 5% NaOH gives III; addn. of the NaOH to IV in EtOH gives I. *2,4-Dinitrophenylhydrazone* of IV, reddish orange, m. 278 80°. Heating III at 100° with concd. H_2SO_4 for 0.5 hr. gives *β-isodunnione* (V), orange-red, m. 129–31°; it is sol. in aq. $NaHSO_3$, is sensitive to sunlight (turns brown in a few min.) and gives in aq. NaOH a red color which remains after boiling for 5 min. Heating V with 20% HCl for 0.5 hr. gives *α-isodunnione*, yellow, m. 118–19°. *α-Lapachone 2,4-dinitrophenylhydrazone*, brownish orange, m. 277–8°; *β-isomer*, orange, m. 282–5°. Oxidation of I with acid $KMnO_4$ gives $C_6H_3(CO_2H)_3$ (VI); III and H_2O_2 in AcOH also give VI. I and H_2O_2 in dil. NaOH give AcH, VI and an *acid* (VII), $C_{12}H_{12}O_4$, m. 205–6°; III gives AcH and VII. CrO_3 oxidation of I or III gives about 1.3 moles of AcOH, suggesting the presence of 1 side-Me group. The behavior on acidification of an alk. soln. of III indicates the presence in the mol. of a ring system which is opened by alkalies and closed by acids. Tentative formulas for I and III are:

(I) (III)

Labile union of oxygen to carbon: special study of the spontaneous dissociation of photoöxydiphenyldimethoxyanthracene. Charles Dufraisse, Léon Velluz and Mme. Léon Velluz. *Compt. rend.* **209**, 516–18(1939); cf. *C. A.* **33**, 6294[7].—During the spontaneous decompn. of the photoöxide of 9,10-diphenyl-1,4-dimethoxyanthracene the O is emitted in an active state which is not understood. Rachel Brown

Anomalous halides. V. Anomalous halides of anthanthrene and attempts to prepare monohalides of *peri*-naphthindenone. Kurt Brass and Erich Clar. *Ber.* **72B**, 1882–4(1939); cf. *C. A.* **33**, 4983[8].—As shown in the ear-

lier papers, perylene and benzanthrone form with Br and I deeply colored compds. which in their simplest compn. are unpaired (monomol.), but the fact that the compd. of benzanthrone with 1 atom of Br is diamagnetic would seem to indicate that the formula of this and possibly the other analogous compds. should be doubled. This complicates the question of their structure, for the unpaired formulation would more satisfactorily explain their high reactivity and deep color. They are provisionally designated "anomalous" halides to differentiate them from the normal halogen addn. products, to which group they certainly do not belong. The prepn. of further such anomalous halides seemed to be the best means of clearing up their structure. Anthanthrene (I) and *peri*-naphthindenone (II) have been found to behave like perylene and benzanthrone, resp., in their behavior toward Br and I. I, m. 262°, with I in boiling thiophene-free benzene gives 92% of a *triiodide*, gleaming, almost black needles, begins to sinter (evacuated tubes) at 150° and slowly melts up to 250°, when gas is evolved. In finally powd. state it slowly loses I in the air with regeneration of I. Titration in benzene suspension with aq. $Na_2S_2O_3$, a few drops of KI, I and starch paste gave 2.957–2.971 atoms I per mol. of I, and the titrated soln., after removal of the benzene with steam, yielded pure I. With 3 parts Br in benzene at 30°, I gives a deep-brown ppt. which decomps. in a few mm., becoming orange-yellow. Attempts to analyze the primary product were unsuccessful; its orange-yellow transformation product, whose Br content (Carius) was 17.72% (calcd. for a mono-Br deriv., 22.51%), contained no Br titratable with $Na_2S_2O_3$; treatment with Br in benzene no longer gave a dark ppt. The faintly yellow, rather concd. soln. of II (m. 153°) in benzene yielded with Br an orange-yellow cryst. product which, however, lost Br on filtration and washing with benzene so that titration showed only about 0.6 atom of active Br. The I compd. behaved similarly. The results so far obtained indicate that a compact arrangement of the benzene nuclei is necessary for the formation of these anomalous halides; hydrocarbons contg. hexagons with only 1 side in common do not form such compds. Compact structure alone is not sufficient, however; pyrene behaves normally while its highly condensed deriv. pyranthrone has a tendency to form an almost black addn. product with Br. C. A. R.

Condensation products of phenols and ketones. IV. *o*-Cresol with acetone. Wilson Baker and D. M. Besly. *J. Chem. Soc.* **1939**, 1421–4; cf. *C. A.* **33**, 2520[2].—Refluxing a mixt. of 100 g. *o*-MeC_6H_4OH, 250 cc. AcOH, 75 cc. Me_2CO and 190 cc. concd. HCl for 60 hrs. and purifying through the di-Ac deriv. give 22 g. *6,6'-dihydroxy-3,3,5,3',3',5'-hexamethylbis-1,1'-spirohydrindene* (I), $C_{23}H_{28}O_2$, m. 245–6° (Niederl, *C. A.* **22**, 3629; **23**, 2431, gives 245°; he termed the product di-*o*-cresylphorone and gave the formula $C_{23}H_{30}O_3$); I also results from [3,4-Me(HO)C_6H_3]$_2CMe_2$ and concd. HCl in AcOH, *o*-MeC_6H_4OH being liberated. Di-Ac deriv. of I, m. 266–7° (Sükösd, *C. A.* **27**, 1873, gives 263–4° and the formula $C_{27}H_{32}O_4$). The *di-Bz* deriv. exists as an *α-form*, transparent rhombs, m. 170–1°, or a *β-form*, opaque prisms, m. 201°; *di-p-nitrobenzoate*, pale yellow, m. 247–8°; *di-Me ether*, m. 158–9°; the last exists as prismatic needles which, when recrystd., give thick tablets. 7,7'-Di-Br deriv., m. 224° (N. gives 220°). Oxidation of I with $KMnO_4$ in AcOH gives a small quantity of phoronic anhydride. HNO_3 and I in AcOH, heated on the water bath for 1 hr., give 2 NO_2 derivs., yellow, m. 233–4° and 225° (both with decompn.), which are probably degradation products. C. J. West

The synthesis of 9,10-dialkylanthracenes. W. E. Bachmann and J. M. Chemerda. *J. Org. Chem.* **4**, 583–7 (1939); cf. *C. A.* **33**, 8604[4].—A synthesis of 9,10-dialkylanthracenes has been developed. *9,10-Dimethylanthracene* (I) is prepd. from anthrone (II) according to Barnett and Matthews (*C. A.* **20**, 2677, 3003) from 9-methylanthrone (cf. Meyer and Schlosser, *C. A.* **14**, 2925) in 15–20% yield. By the same method *9,10-dibenzylanthracene*, m. 243–5°, is obtained in 17% yield (cf. Barnett and Cooke, *C. A.* **22**, 1972). A much more satisfactory method for prepg. I is developed based on the procedure of prepn. of 9,10-dimethyl-1,2-benzanthracene (cf. *C. A.* **32**, 4978[3]). As a general procedure 10.4 g. anthraquinone (III) is placed in a Soxhlet thimble and a Grignard soln. is prepd. from 10 cc. MeI in 100 cc. Et_2O in the extn. flask. III is added to the Grignard soln. by refluxing the Et_2O on a water bath. After 2.5 days most of the III is dissolved. The Et_2O suspension of the addn. compd. is hydrolyzed, the Et_2O evapd. and the insol. product filtered and dried. It is dissolved in hot NaOH, a small amt. of III is removed by filtration and the hot MeOH soln. is treated with a soln. of NaOH and $Na_2S_2O_4$ and much H_2O. *9,10-Dimethyl-9,10-dihydroxy-9,10-dihydroanthracene* (IV) (8.5 g.) is filtered and washed with H_2O. After recrystn. from MeOH, IV m. 185–95°. When 5 g. IV in 25 cc. C_6H_6 and 25 cc. MeOH contg. 5 drops H_2SO_4 are kept at room temp. for 0.5 hr., then much H_2O is added and the benzene soln. is treated with dil. NH_4OH, 5.36 g. *9,10-dimethyl-9,10-dimethoxy-9,10-dihydroanthracene* (V), m. 197° (cf. Guyot and Stæchling, *Bull. soc. chim.* [3], **33**, 1144 (1905)), is isolated. On treating 5.36 g. V with 0.82 g. powd. Na in 30 cc. Et_2O and 30 cc. C_6H_6 by shaking the mixt. for 4 days, 2.54 g. I is obtained. From the Et_2O-C_6H_6 filtrate after treating with HCl, an addnl. 1.25 g. I is obtained. In the same way as IV, *9,10-diethyl-9,10-dihydroxy-9,10-dihydroanthracene* (VI), m. 169–71° (Clarke and Carlton, *C. A.* **6**, 611, found 175°), is prepd. Treatment of VI with MeOH and H_2SO_4 yields *9,10-diethyl-9,10-dimethoxy-9,10-dihydroanthracene* (VII), m. 179–80.5°. When VII is shaken with powd. Na in a mixt. of Et_2O and C_6H_6, *9,10-diethylanthracene*, m. 146–7°, in 95% yield, is obtained. Its *picrate* m. 128–9°. *2,9,10-Trimethyl-9,10-dihydroxy-9,10-dihydroanthracene* (VIII) is prepd. in the same way from β-methylanthraquinone. VIII m. 112 30°. It retains solvent of crystn. quite tenaciously. Methylation of VIII with MeOH and H_2SO_4 yields *2,9,10-trimethyl-9,10-dimethoxy-9,10-dihydroanthracene* (IX) m. 181.5–2.5°. When treated with powd. Na, IX gives *2,9,10-trimethylanthracene* in 85% yield. When sublimed and allowed to crystallize slowly from EtOH it m. 100–1°; when recrystd. rapidly it m. 95 6°. Its *picrate* m. 162–2.5°. F. E. Brauns

Influence of substituents in the benzanthrone nucleus on its destructive oxidation. G. Charrier. *Atti X° congr. intern° chim.* **3**, 58–64 (1939); cf. *C. A.* **33**, 2133[8].—A summary of the influence of substituents on the course of oxidation of benzanthrone and its derivs. with different oxidizing agents (e. g., $KMnO_4$, CrO_3, O, O_3). 34 references. J. C. Lo Cicero

Photoreactions. IV. Photoreaction between phenanthraquinone and aromatic aldehydes. A new passage from phenanthraquinone to fluorenone. Alexander Schönberg and Radwan Mostbacher. *J. Chem. Soc.* **1939**, 1430–2; cf. *C. A.* **30**, 2850[1].—Phenanthraquinone (I) (5 g.) and 10 g. BzH in a sealed quartz tube, kept in sunlight for 4 days, give 6.5 g. of the *phenylhydroxymethylene oxide* (II) of 9,10-dihydroxyphenanthrene (III), m. 177–8° (cf. Klinger, *Ann.* **249**, 137 (1888), who believed it to be the *O*-Bz deriv. of III); heating 0.25 hr. at 90° with HNO_3 (d. 1.30) gives I; CH_2N_2 gives the *phenylmethoxymethylene ether* of III, m. 80°. I (2 g.) and *p*-ClC_6H_4CHO give 3 g. of the *p-chlorophenylhydroxymethylene ether* (IV) of III, m. 222° (decompn.); *Me ether* (V), m. 170°. Hydrolysis of V with 20% NaOH at 40° for 0.5 hr. gives I and *p*-$ClC_6H_4CO_2Me$. Thermal decompn. of IV gives fluorenone, I, BzOH and BzH. α-Stilbenediol diacetate heated at 165° gives benzil. C. J. West

The synthesis of 2-methylphenanthrene from *l*-menthone. Ruby Murray Orcutt and Marston T. Bogert. *J. Org. Chem.* **4**, 543–7 (1939).—When methyl-1-phenethylcyclohexanols are cyclodehydrated, a Me group in position 3 on the cyclohexane nucleus causes the cyclization to occur on C atom 6 of the same nucleus (cf. *C. A.* **31**, 1296[6]; **32**, 921[2]; Kon, *C. A.* **27**, 5336). The cyclization takes place even when an iso-Pr group is attached to C atom 6. This fact is taken advantage of for the synthesis of *2-methylphenanthrene* (I) from *l*-menthone (II). II (15.4 g.) in 20 cc. dry Et_2O is added to a well-cooled

soln. of $Ph(CH_2)_2MgBr$, prepd. from 23.4 g. $Ph(CH_2)_2Br$, in 75 cc. Et_2O, stirred for 2 hrs. and kept overnight at room temp. After decompn. of the mixt. with acidified H_2O, the mixt. is extd. with Et_2O, and Et_2O soln. evapd. and the residue distd. at 2 mm. Repeated fractionation gives *1-phenethyl-3-methyl-6-isopropylcyclohexanol* (III), b_2 167-9°, in 50% yield. When 3 g. III is allowed to react with PhNCO with exclusion of moisture, carbanilide slowly seps. The residual liquid is removed with petr. ether, the soln. washed with H_2O and allowed to stand with H_2O overnight. It is then filtered, the filtrate is dried, concd. and distd. over Na. *1-Phenethyl-2-isopropyl-5-methylcyclohexene* (IV) (2.7 g.), b_4 145°, is obtained. IV is highly unsatd. and is not cyclized when it is shaken in petr. ether 3 times with cold 90% H_2SO_4. With concd. H_2SO_4, IV is rearranged and *2-methyl-12-isopropyl-1,2,3,-4,9,10,11,12-octahydrophenanthrene* (V) is formed in nearly quant. yield. Distd over Na, V b_2 123–7°. Dehydrogenation of V by successive addn. of 15 g. Se to 7 g. V at 345 65° for a total of 50 hrs. gives on extn. with EtOH and treating the ext. with Norit, a soln. from which, on standing, a dark oil seps. This is sepd. into 2 fractions, one (VI), 3 g., b_3 185–55°, the other (VII) b_3 155–60°. From VII, 2 g. I, m. 56°, crystallizes (cf. Haworth, *C. A.* 26, 3503; Sengupta, *C. A.* 33, 3370[3]). VI when retreated with Se gives another 0.8 g. I. The picrate of I m. 117.5–18.5° (cor.). Oxidation of 2 g. V in 20 cc. AcOH with 10 g. Cr_2O_3 in 10 cc. AcOH and 10 cc. H_2O added in 5 successive portions yields about 1 g. *2-methyl-12-isopropyl-1,2,3,4,11,12-hexahydrophenanthraquinone* (VIII), m. 151°, as yellow needles which are immediately decolorized by $Na_2S_2O_4$. With cold concd. H_2SO_4, VIII gives a deep amber soln. Its *quinoxaline* m. 121° (cor.). When VIII is shaken with a cold NaOH soln. and the alk soln. is acidified, *2-methyl-9-hydroxy-11-isopropyl-1,2,3,4,10,11-hexahydrofluorene-9-carboxylic acid* (IX) is formed, which when heated rapidly in a sealed tube m. 215–22° (cor.) to a viscous mass insol. in cold alkali. In 1 expt. IX is obtained directly with alk. treatment, indicating that VIII may undergo rearrangement even in the absence of alkali When 1 g. VIII in 20 cc. AcOH is refluxed for 8 hrs. with 10 cc. H_2O_2, the AcOH is distd. off, the residue dissolved in *N* NaOH, and the filtered soln. is acidified, an oily product seps. which is extd. with Et_2O and the Et_2O soln. is dried and evapd. The residue after crystn. from dil. AcOH and twice from dil. EtOH gives about 1 g. *1-isopropyl-4-methyl-1,2,3,4,5,6-hexahydrobiphenyl-2,2'-dicarboxylic acid*, m. 194–8° (cor.), with the formation of a yellow anhydride. F. E. Brauns

Aromatic hydrocarbons. XXIV. Hexacene, a green simple hydrocarbon. E. Clar. *Ber.* **72B**, 1817-21(1939); cf. *C. A.* **34**, 947.—According to Bentley, *et al.* (*C. A.* 2, 540) 1,5-$C_{10}H_6(OH)_2$ (I) undergoes 2-fold condensation with $C_6H_4(CO)_2O$ (II) by the H_3BO_3 method to give a dicarboxylic acid, 2,6,1,5-(*o*-$HO_2CC_6H_4CO)_2C_{10}H_4(OH)_2$, but on attempted ring closure a phthalic acid residue is apparently split off and instead of the expected linear 6-ring *7,15-dihydroxyhexacene-5,16,8,13-diquinone* (III) there is obtained a naphthacene deriv. In the present paper is described the prepn. of III in 1 operation in 45-8 g. yield by gradually adding 16 g. I and 40 g. II to a fused mixt. of 120 g. $AlCl_3$ and 24 g. NaCl at 200°, heating 0.5 hr. at 210°, cooling to 110°, pouring into dil. HCl, at once heating to boiling, filtering and washing with much hot water. The alkali-sol. impurities still present are removed by boiling out with dil. NaOH, whereby the III is converted into an insol. blue salt. This is further purified by converting it into the vat dye with alk. $Na_2S_2O_4$, passing in air and decompg. the salt in boiling water suspension with HCl. The red-brown III crystallizes from $PhNO_2$ or sublimes *in vacuo* in CO_2 in red-brown needles with green surface luster, slowly becomes fluorescent (blue) above 300° in evacuated tubes, forms a brown vat with alk. Na_2SO_4 and dissolves in concd. H_2SO_4 with blue color. It is also obtained, frequently in better but also in greatly varying yields, by adding powd. $AlCl_3$ to a suspension of I and II in $(CHCl_2)_2$, heating 1 hr. at 130° with stirring, decompg. with ice and dil. HCl, removing the $(CHCl_2)_2$ with steam and extg. the residue with dil. Na_2CO_3. Heated with 1 part NaCl, 6 parts $ZnCl_2$ and 1 part Zn dust at 210° and then, in the course of a few min., to 280°, it gives *5,16-* or *6,15-dihydrohexacene* (IV), subliming *in vacuo* in CO_2 at 300° in orange-red leaflets whose strongly orange-yellow soln. in xylene lightens considerably on boiling and then deposits lighter crystals, m. 357-8° (evacuated tubes) (Marschalk, *C. A.* **33**, 7294[9], gives 369–70° (cor. (?)). IV sublimed with Cu powder *in vacuo* in CO_2 at 300–20° gives the linear 6-ring *hexacene* (V) in deep-green crystals (large crystals appear almost black with steel-blue luster), decomps. at elevated temps. without melting, slowly dissolves in concd. H_2SO_4 with green color, very difficultly in org. solvents. The green solns. are extremely sensitive to light and air and are immediately decolorized by maleic anhydride. Because of the sensitivity of V it is very difficult to obtain its absorption spectrum; a very cursory observation gave about 6900 A. for the position of the 1st band, giving for *K* in the equation $\sqrt{R_p/\nu} = \sqrt{R_p}\cdot\lambda - K$ (*C. A.* **30**, 8205[9]) the value 10.87 (calcd. 11) and leaving no doubt as to the linear structure of V.

C. A. R.

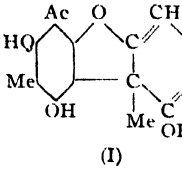
Oxidation products of pyrrolic amines. III. Tommaso Ajello. *Gazz. chim. ital.* **69**, 453-9(1939); cf. *C. A.* **33**, 3786[1].—To ascertain whether the properties of triphenylpyrroleninehydroxylamine are common to other members of the same series, the attempt was made to prep. other pyrrolic hydroxylamines by the same procedures as before, viz., reduction of the isonitrosopyrroles (cf. *C. A.* **31**, 3476[6], 3480[1]), and oxidation of the corresponding amines (cf. *C. A.* **33**, 3786[1]). Reduction of isonitrosomethylphenylpyrrole by various methods did not give definite results in any case, because of its great sensitivity to both reducing agents and acids. Zn + AcOH, Fe + AcOH, and Cu + AcOH give reddish amorphous substances with basic properties (ppts. with picric acid and with alkaloid reagents). No definite products could be isolated with Zn + NH_4Cl, Al-Hg, Al-K, Zn-K, $(NH_4)_2S$, etc. With salts such as $FeSO_4$ and CuCl, the only definite product was methylbenzoylisoxazole (cf. *C. A.* **32**, 4557[7]). Reduction of isonitrosodiphenylpyrrole (I) by Zn, Fe and Cu in hot AcOH and Al-K, Al-$HgCl_2$ and $(NH_4)_2S$ in alk. medium gives aminodiphenylpyrrole (II). With ferrous salts and cuprous salts in acid medium hydrolysis occurs and the product is phenylbenzoylisoxazole (cf. *loc. cit.*). A suspension of I (4 g.) in glacial AcOH (80 cc.) and powd. Cu (4 g.), allowed to stand (with agitation) for 2–3 days (during which time 4 g. more of Cu are added and Cu-$(OAc)_2$, which impedes the reaction, is removed), the green liquid decanted into water (600 cc.), $(NH_4)_2SO_4$ added, filtered, the soln. (yellow with violet fluorescence) made alk., the yellow ppt. (III) withheld, the filtrate extd. with Et_2O, III in EtOH or Me_2CO added to the Et_2O ext., clarified, extd. with water (to remove EtOH or Me_2CO), the Et_2O layer dried by Na_2SO_4, concd. and the ppt. purified by soln. in Me_2CO, diln. with Et_2O, clarification, washing with water, etc., yield *asoxydiphenylpyrrole*,

(IV), yellow, m. 170-2°, basic properties, sol. in mineral acids (reppld. by alkalies). These acid solns. are stable when cold but decomp. when boiled (change from yellow to orange to red) with sepn. of an amorphous red substance from which no definite compds. could be sepd. During the cryoscopic detn. of the mol. wt. of IV in AcOH, alternate freezing and thawing lowered the m. p. progressively, indicating decompn. even at low temps. IV in dil. AcOH and excess picric acid pptd. the *picrate*, $C_{32}H_{24}ON_4.C_6H_2(NO_2)_3OH$, m. 180° (decompn.). II in glacial AcOH and perhydrol, allowed to stand for 2 days, dild. with water, filtered, made alk. with NH_4OH and the product isolated as in the reduction of I by Cu, give a low yield of IV. Also II in AcOH and CrO_3 heated at 100° for 30 min., dild. with water, made alk. with NH_4OH and isolated as before, gives a low yield of IV. Alc. II and aq. $FeCl_3$, refluxed for 1 hr., dild. with water, filtered, made alk. with NH_4OH and extd. with Et_2O, give a very low yield of IV. IV is reduced

to II by all ordinary reducing agents, both acid and alk. In the formation of IV by reduction of I or by oxidation of II, intermediate compds., such as NH_2OH and azo and hydrazo derivs., are probably formed, and it should be possible to find conditions under which they can be isolated. C. C. Davis

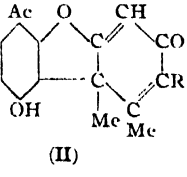
Oxidation of *d*(+)-proline by *d*-amino acid oxidase. Hans A. Krebs. *Enzymologia* **7**, 53–7(1939)(in English).—*d*-Amino acid oxidase (previously known as *d*-amino acid deaminase) oxidizes *d*(+)-proline to form α-keto-δ-aminovaleric acid (I). I reacts with 2,4-dinitrophenylhydrazine to form *α-keto-δ-aminovaleric acid 2,4-dinitrophenylhydrazone* (II), m. 223° (not cor.). II forms a *HCl salt* (III) and a H_2SO_4 *salt*. III m. 233 42° (decompn.) (not cor.). (−)-Ornithine also yields I when oxidized by *d*-amino acid oxidase. Felix Saunders

Active principles of leguminous fish-poison plants. III. The structure of elliptone. Stanley H. Harper. *J. Chem. Soc.* **1939**, 1424–7; cf. *C. A.* **33**, 7792⁹.—In the prepn. of dehydroelliptone (I) from *l*-elliptone (II) by 1-AcONa there also results *O-acetylelliptolone* (III), m. 175.5°; heating III above its m. p. gives I_2, AcOH being evolved. I also results in a quant. yield by refluxing III with 5% EtOH-H_2SO_4 for 8 hrs. Refluxing III with 0.5 *N* EtOH-KOH for 2 hrs. gives *elliptolone*, $C_{20}H_{16}O_7$, m. 228°; 5% EtOH-KOH gives I. I (2 g.), 8 g. Zn and 20 cc. 15% KOH in 60 cc. EtOH, refluxed 2 hrs., give 1.68 g. of *elliptic acid*, $C_{20}H_{18}O_8$, m. 190°, which gives a blue-green color with $FeCl_3$; *Me ester*, m. 143°; alk. H_2O_2 at 60° gives derric acid. Refluxing 5 g. II in 5% EtOH-KOH for 2 hrs. gives 120 mg. of *4-hydroxycoumarone-5-carboxylic acid*, m. 221°, which gives a deep-blue color with $FeCl_3$; *Me ester*, m. 105°; the acid was synthesized by passing CO_2 through 4-hydroxycoumarone and MeONa in MeOH at 180°. These results establish the formula for I proposed in part II. *Rotenone* α- and β-*oximes*, m. 237° and 249°; the α-form, seeded with the β-form, deposits the pure β-oxime but the α-form with the α-oxime gives only the β-form; thus, this is a case of dimorphism. This is also true of the oximes of *l*- and *dl*-II.



C. J. West

Thiophene series. XLIX. Constitution of indophenins. Wilhelm Steinkopf and Werner Hanske. *Ann.* **541**, 238–60(1939); cf. *C. A.* **33**, 8196¹.—The Grignard reagent (I) from 53 g. 2-iodothiophene (II) and 6 g. I in 100 cc. C_6H_6, added to 14.8 g. of isatin in 500 cc. C_6H_6 during 30 min., heated 15 min. and treated with 500 cc. 10% NaOH, gives 14.3 g. of *3-(2-thienyl)dioxindole* (III), m. 208–8.5°; heating with NaOH 0.5 hr. gives the Na salt of 2-thienyl-*o*-aminomandelic acid, the diazo compd. of which gives a red dye with β-$C_{10}H_7OH$. III yields a *di-Bz deriv.*, m. 159°. Heating 3.5 g. of III with $ZnCl_2$ at 180° for 15 min. gives 40 mg. of isatin(thiophen)indophenin, which may be recrystd. from BzOEt or C_5H_5N; this is identical with the product prepd. by S. and Heimpel (*C. A.* **26**, 3793). I from 4.6 g. II and Et 5-bromoisatin-1-acetate in Et_2O give 5.9 g. of *Et 3-(2-thienyl)-5-bromodioxindole-1-acetate*, m. 124–5°; warming 3.7 g. in 150 cc. AcOH with 120 cc. concd. H_2SO_4 and 40 cc. AcOH at 55–60° gives 0.15 g. of Et 5-bromoisatin(thiophen)-1-acetate, blue (S. and H.). The I from 5.3 g. of II in 20 cc. C_6H_6 and 3 g. of 1-methylisatin in 100 cc. C_6H_6 give 1.5 g. of *1-methyl-3-(2-thienyl)dioxindole*, m. 127.5–9°, which gives the indophenin with AcOH-H_2SO_4. *5-Bromo-3-(2-thienyl)dioxindole*, m. 214.5° (decompn.); AcOH-H_2SO_4 gives the indophenin. The I from 10.6 g. of II and 8.8 g. of Et mesoxalate in Et_2O give mesoxophenin (di-Et mesoxalate(thiophen)indophenin) (IV); hydrolysis with KOH in dioxane-MeOH gives the yellow-red K salt of glyoxylic acid(thiophen)indophenin. IV and Zn in AcOH give *di-Et 2,2'-dithienyl-5,5'-bis(malonate)*, pale yellow, m. 111.5–12.5°; hydrolysis with KOH in EtOH (30 min.) and acidification with 50% AcOH give *2,2'-dithienyl-5,5'-bisacetic acid*, m. 217°; *Me ester*, yellow, m. 75.5–7°; decarboxylation gives 5,5'-dimethyl-2,2'-bithienyl (VI), m. 65.5–6.5°. The I from 5.3 g. of II and $PhCOCO_2$-Et (VIA) give 2 g. of *Et α-(2-thienyl)mandelate* (VII), $b_{0.3}$ 136°, m. 59.5–60.5°; 0.8 g. of the ester with 20 cc. concd. H_2SO_4, shaken for 5 min., gives 10 mg. of *Et phenylglyoxylate(thiophen)indophenin* (VIII), red-violet, m. 208°, which has a green metallic luster on rubbing; this also results on melting VII with $ZnCl_2$ and in 0.9-g. yield from 4.2 g. of VIA and 3 g. thiophene in 320 cc. petr. ether at 0° with 55 cc. ice-cold H_2SO_4; the free *acid* (IX) m. 208–10° (decompn.); the *K salt* forms red needles. VIII with Zn in boiling AcOH gives the *Et ester*, pale yellow, m. 95–6.5°, of *2,2'-bithienyl-5,5'-bis(α-phenylacetic acid)*, yellow, m. 70–85° (decompn.); decarboxylation gives VI. 2,2'-Bithienyl (3.4 g.) and 9 g. of BzCl in C_6H_6 with 7 g. $TiCl_4$ give 1.2 g. *5,5'-dibenzoyl-2,2'-bithienyl* (X), orange, m. 250–2°; this also results from IX in NH_3 conc'd. H_2SO_4 gives an intense green-yellow fluorescence; Zn in AcOH gives a blue-red color. X yields a *3,3'-di-Br deriv.*, pale reddish yellow, m. 195–7°. The I from 10.5 g. II and 10.5 g. of benzil give a yellow-white ppt. which with CH_2N_2 yields the *Me ether* of *ms-(2-thienyl)desoxybenzoin* (XI), m. 71–2°. XI (80 g.) in 500 cc. AcOH and 500 cc. concd. H_2SO_4 in 900 cc. AcOH at 45–50° for 20 min. give *benzil(thiophen)indophenin* (XII), golden green, becoming blue on rubbing, m. 223°. Benzil and thiophene in $ClHCl_2$, shaken with concd. H_2SO_4 give *ms-bis(2-thienyl)desoxybenzoin*, m. 103.5–4°. XII and Zn in AcOH give *5,5'-bis(phenylbenzoylmethyl)-2,2'-bithienyl*, m. 219.5–20.5°, which with EtONa gives *5,5'-dibenzoyl-2,2'-bithienyl* (XIII), m. 96.5–7.5°. This proves the presence of a 2,2'-bithienyl nucleus in indophenins. Thiophene (30 g.) and 30 g. $PhCH_2OH$ with 30 g. $ZnCl_2$, gently boiled 0.5 hr., give (from 100 g. thiophene in 3 lots) 42 g. of recovered thiophene, 51 g. of *2-benzylthiophene*, b_1 257–62°, and 23 g. of *2,5-dibenzylthiophene*, b_{12} 220–2°. 5-Chloromercuri-2-benzylthiophene with 1-KI at 50° gives *5-iodo-2-benzylthiophene*, m. 55–7°; with Natum-kupfer C at 185–90° and then at 190–210° there results 14% of XIII. I and Ac_2 in Et_2O give *ms-(2-thienyl)acetone*, pale yellow, b_1 82°. Cumaran-2,3-dione (15 g.) and 8.4 g. thiophene with concd. H_2SO_4 in AcOH (0.5 hr. at 55°) give 90 mg. of *cumaran-2,3-dione(thiophen)indophenin*, green-gold, does not m. 300°. The Grignard reagent from 9.8 g. of 5-iodo-2-thiotolene and 9.2 g. of benzil give 5.7 g. of *ms-(2-methyl-5-thienyl)benzoin*, m. 78–9°; AcOH-H_2SO_4 gives a blue color, which quickly turns to a dirty red-brown; heating with BzOH at 180° gives a blue powder. The Grignard reagent from 2,5-dibromothiophene gives *ms-(2-bromo-5-thienyl)benzoin*, m. 99–100.5°; cold concd. H_2SO_4 gives only a yellow halochromy; on warming the yellow color changes to blue but H_2O ppts. only brown flakes. The action of CO_2 upon the Grignard reagent from 2,5-diiodo-3-thiotolene gives *2-iodo-3-thiotolene-5-carboxylic acid*, m. 172–3°. Structures proposed for indophenins are discussed in the light of the above expts. L.



Derivatives of 3,4-dibromothiophene-2,5-dialdehyde and macrocyclic compounds. Wilhelm Steinkopf, Reinhard Leitsmann, A. Herbert Müller and Helmut Wilhelm. *Ibid*, 260–82.—3,4-Dibromothiophene-2,5-dialdehyde (I) with Ac_2O-AcONa, heated at 170–5° for 1.5 hrs., gives 50% of *3,4-dibromothiophene-2,5-diacrylic acid*, light yellow, does not m. 350°, sublimes in a high vacuum at 220°; *acid chloride*, yellow, m. 172° (decompn.). I and $PhNH_2$ in AcOH at 95° give the *dianil*, light yellow, m. 245° (rapid heating); *di(o-hydroxyanil)*, orange, m. 214° (decompn.); I and quinaldine (II) in Ac_2O give 76% of *3,4-dibromo-2,5-bis(β-quinolyl-2-ethylene)thiophene*, brownish yellow, m. 247–8°; the *di-HCl salt* is fiery red. Isophthalaldehyde (III) and II in Ac_2O give *m-bis(β-quinolyl-2-ethylene)benzene*, nearly colorless, m. 180°; mineral acids form yellow addn. products; *p-isomer*, light greenish yellow, m. 243°; mineral acids give orange salts. Terephthalaldehyde (IV) gives an ivory-colored *dianil*, m. 159°; the *bis(o-hydroxyanil)* is yellow and m. 215°. 5,5'-Dimethyl-2,2'-bithienyl (V) (4.3 g.) and 15.5 g. Br in CS_2 give 93% of the *3,4,3',4'-tetra-Br deriv.* (VI), Ag-gray, m. 255°; 4 g. VI and 4 cc. Br at 70°, illuminated for 2 hrs., give 11–15% of the *5,5'-di(bromomethyl) deriv.*, pale yellow, m. 210°. Passing Cl into a warm soln. of V in AcOH gives 55% of the *3,4,3',4'-tetra-Cl deriv.* (VII), m. 201°; treating VII in boiling CS_2 with Cl for 3 hrs. (sun-

light) gives 55 g. of the *5,5'-bis(dichloromethyl) deriv.* (VIII), m. 119-20°. Boiling 0.5 g. VIII with 50 cc. aq. $Ca(OH)_2$ and 0.3 g. $CaCO_3$ for 4–5 hrs. and subliming the product at 170–200° give 50% of *3,4,3',4'-tetrachloro-2,2'-bithienyl-5,5'-dialdehyde* (IX), golden yellow, m. 179°; $N_2H_4.H_2O$ in AcOH gives the *diazine*, dark red, shows no m. p.; II and IX in AcOH give *3,4,3',4'-tetrachloro-5,5'-bis(β-quinolyl-2-ethylene)-2,2'-bithienyl*, deep orange, m. 284°. I and $C_2H_4(NH_2)_2$ in dioxane-H_2O give *bis(3,4-dibromo-2,5-thioxal)ethylenediamine*, pale-brown amorphous compd., which gives an orange color with concd. H_2SO_4 or red with concd. HCl; IV gives *bis(p-xylal)ethylenediamine*, yellow; with *o*-$C_6H_4(NH_2)_2$ IV gives *1,4-bis(2-benzimidazolyl)benzene*, pale yellow, unchanged at 300°, shows a blue fluorescence in alk. soln. under the quartz Hg lamp. I (2 g.) and 3 g. *o*-C_6H_4-$(NH_2)_2$ in AcOH, heated on the water bath for 0.25 hr., give a ppt. (0.24 g.) of *bis(3,4-dibromo-2,5-thioxal)-o-phenylenediamine* (X), chocolate-brown, decomps. 262°, and from the filtrate 1.3 g. of *3,4-dibromo-2,5-bis(2-benzimidazolyl)thiophene*, yellow, m. 385°; the AcOH soln. shows a pale bluish green fluorescence. I and *m*-C_6H_4-$(NH_2)_2$ give the *m-phenylenediamine* isomer of X, olive-brown. I and $(2\text{-}H_2NC_6H_4)_2$ in boiling AcOH give *bis(3,4-dibromo-2,5-thioxal)-2,2'-diaminobiphenyl*, yellow, m. about 230°; concd. H_2SO_4 and HCl give red solns. III and diaminodurene in hot EtOH give *bis(m-xylal)diaminodurene*, yellow, amorphous; IV gives the *p-isomer*, brown-yellow. I and benzidine give a poor yield of *3,4-dibromo-2,5-thioxalbisbenzidine*, brown-golden, does not m. 450°; reaction in BzOEt with I in AcOH gives *bis(3,4-dibromo-2,5-thioxal)benzidine*, brown and giving a violet-blue soln. in H_2SO_4. III gives *bis(m-xylal)benzidine*, light-olive, sol. in concd. H_2SO_4 with a yellow, in concd. HCl with a brown-orange, color. I and $(p\text{-}H_2NC_6H_4)_2CH_2$ in hot AcOH give *bis(3,4-dibromo-2,5-thioxal)-4,4'-diaminodiphenylmethane*, fiery yellow. *Bis(p-xylal)-4,4'-diaminodiphenylmethane*, pale yellow, gives a red color with H_2SO_4 and a black-red color with HCl. I and (*p*-AcNHC$_6$H$_4$)$_2$ in AcOH give *3,4-dibromothiophene-2,5-dialdehyde bis(p-acetaminoanil)*, yellow, decomps. above 300°; *terephthalaldehyde bis(p-acetaminoanil)*, light yellow, m. 320-2°. I (3 g.) and 15 g. $PhNMe_2$ with 8 g. $ZnCl_2$, heated 3 hrs. at 110-20°, and purification by pptn. with NH_4OH from a HCl soln., give 6 g. of *3,4-dibromo-2,5-di[bis(p-dimethylaminophenyl)methyl]thiophene* (leuco base of XI), m. 246°; with MnO_2 in dil. H_2SO_4 there results the *carbinol base*, $C_{38}H_{42}O_2N_4Br_2S$, amorphous, pale-brown powder, m. 180-5°; EtOH gives a green color; this base with H_2SO_4 in EtOH, warmed on the water bath, gives *3,4-dibromothiophene blue* (as the *acid sulfate*) (XI), violet-brown, which gives a blue-violet color; the C_5H_5N soln. is decolorized on standing, the EtOH and AmOH solns. are colored green. Similarly IV gives *1,4-di[bis(p-dimethylaminophenyl)methyl]benzene*, (XIA) m. 244-5° (decompn.); the *carbinol base* (*1,4-di[bis(p-dimethylaminophenyl)hydroxymethyl]benzene*) (XII), pale gray, m. 160-5°; the *color base* (as the *acid sulfate*) (XIII) is a violet powder with a brown surface luster and gives a blue-green soln. III gives the *1,3-isomer* of XIA, m. 147–9°; *1,3-isomer* of XII, gray, amorphous, m. 135-40°; of XIII, a_0 violet powder. 3,4,5-Tribromothiophen-2-aldehyde with $PhNMe_2$ and $ZnCl_2$ gives *bis(p-dimethylaminophenyl)[2-(3,4,5-tribromothienyl)]methane* (*leuco base* of XIV), m. 159-60°; oxidation gives *tribromothiophene green* (XIV), (as the *acid sulfate*), green. Colors of solns. of I, III and IV in C_6H_6, PhOH, PhOMe, $PhNH_2$ and $PhNMe_2$ are given. C. J. West

Usnic acid. VII. Analogs of usnolic acid. Reginald T. Foster, Alexander Robertson and Thomas V. Healy. *J. Chem. Soc.* **1939**, 1594-1601; cf. *C. A.* **32**, 4560[8].—A brief review of the structures recently proposed for usnic acid (I) leads to the adoption of that first suggested in part V (*C. A.* **31**, 6219[6]) and supported by the work of Schöpf and Ross (*C. A.* **33**, 2505[1]). A new structure (II, R = CO_2H) for usnolic acid (III), based on the formula (II, R = H) which was advanced for decarbousnol in part V, is deduced and its formation from I is discussed. *m*-Me-OC_6H_4OH (15 g.), 14.5 g. $ClCH_2Ac$ and 45 g. K_2CO_3 in 250 cc. boiling Me_2CO (4 hrs.) give 10.2 g. of 3-methoxyphenoxyacetone, b_{20} 150–3° (*2,4-dinitrophenylhydrazone*, pale yellow, m. 146°); concd. H_2SO_4 at 0° for 5 min. gives 6-methoxy-3-methylcoumarone (IV), $b_{0.4}$ 79-82°; reaction of 10 g. IV with HCN and HCl in Et_2O and hydrolysis with H_2O gives 10 g. of *6-methoxy-2-formyl-3-methylcoumarone* (V), m. 105° (*2,4-dinitrophenylhydrazone*, red, m. 262°; semicarbazone, m. 248°); oxidation with $KMnO_4$ gives the corresponding acid, m. 190° (decompn.). Condensation of V with hippuric acid by Ac_2O-AcONa gives the *azlactone*, orange-red, m. 194°; hydrolysis by boiling 10% aq. NaOH gives *6-methoxy-3-methylcoumarone-2-pyruvic acid*, pale yellow, m. 196° (*oxime*, m. 166°); warming with 30% H_2O_2 in 5% aq. NaOH gives *6-methoxy-3-methylcoumarone-2-acetic acid*, m. 145°; H_2SO_4 gives a brown, red and finally purple color; PCl_5 gives a chloride (VI), which yields an *amide*, m. 162°. Reaction of VI with $AcCHNaCO_2Et$ in Et_2O at room temp. for 18 hrs. gives the keto ester which could not be purified; concd. H_2SO_4 at 60° for 1.75 hrs. gives a mixt. of the *Et*

(I)

(II)

ester, m. 122°, and *6'-methoxy-3',3-dihydrobenzofurano-(2',3',5,4)-Δ^{2,5}-cyclohexadienone-2-carboxylic acid* (VII), which seps. as the *hydrate*, yellow, m. 147°; *Me ester*, m. 101°. VII gives an intense bright-blue color in Ehrlich's reaction, identical with that of III. In order to exclude the possibility that the cyclization of the ketone ester to the anhydro compd. might have involved the interaction of the δ-CO group of the side chain with the C atom in the 7-position of the coumarone residue, the homolog in which the 7-position is blocked by a Me group was studied. 3,2,4-Me(HO)(MeO)C_6H_2Ac (20 g.) and $BrCH_2CO_2Et$ with K_2CO_3 in Me_2CO (refluxing 18 hrs.) give 20 g. of the *Et ester*, b_{15} 180-5° (*2,4-dinitrophenylhydrazone*, bright orange, m. 167°), of *3-methoxy-6-acetyl-2-methylphenoxyacetic acid*, m. 133°; refluxing with EtONa for 1 hr. gives the *Et ester*, m. 75°, of *6-methoxy-3,7-dimethylcoumarone-2-carboxylic acid*, m. 225° (decompn.); refluxing with Ac_2O and AcONa gives *6-methoxy-3,7-dimethylcoumarone*, b_{11} 92-3° (*picrate*, bright red, m. 92°); H_2SO_4 gives a pale-yellow and then a blue color; HCN and HCl give *6-methoxy-2-formyl-3,7-dimethylcoumarone*, m. 102° (*2,4-dinitrophenylhydrazone*, red, m. 284°); hippuric acid gives the *azlactone*, crimson, m. 218°; hydrolysis yields *6-methoxy-3,7-dimethylcoumarone-2-pyruvic acid* (VIII), pale yellow, m. 228° (*oxime*, m. 162° (decompn.)); a by-product is *6-methoxy-2,3,7-trimethylcoumarone*, m. 41°, which gives an olive-green and then a blue color with H_2SO_4; *picrate*, deep crimson, m. 103°; hydrogenation yields *6-methoxy-2,3,7-trimethylcoumaran*, a mobile oil. Oxidation of VIII with 30% H_2O_2 in 5% aq. NaOH gives *6-methoxy-3,7-dimethylcoumarone-2-acetic acid*, m. 158°; *amide*, m. 179°; the chloride and $AcCHNaCO_2Et$ give a keto acid, cyclized by concd. H_2SO_4 at 60° (1.75 hrs.) to *6'-methoxy-3',7',3-trimethyl-2',3-dihydrobenzofurano-(2',3',5,4)-Δ^{2,5}-cyclohexadienone-2-carboxylic acid*, pale straw, m. 150°; *Et ester*, m. 115°; the acid gives an intense bright-blue color with Ehrlich's reagent. A detailed comparison of these acids with III clearly indicates that the latter compd. and its synthetical analogs are similarly constituted, thus affording independent evidence in support of the formula II (R = CO_2H). C. J. West

Action of nitric acid on polycyclic indole derivatives. XIII. Indeno(2',3',2,3)indole. N. M. Beyts and S. G. P. Plant. *J. Chem. Soc.* **1939**, 1534-6; cf. *C. A.* **32**, 8412[8].—Indeno(2',3',2,3)indole (3 g.) in Me_2CO contg. 3 g. of 66% KOH, treated gradually with AcCl, gives the *1-Ac deriv.* (I), m. 131°; the *1-Bz deriv.* (II), brown, m.

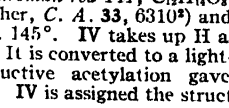
169–70°. I (2 g.) in 13 cc. AcOH at 50°, treated with 0.7 g. of HNO_3 (d. 1.5) in 2.5 g. AcOH, gives 0.5 g. of a *6(?)-NO_2 deriv.* (III), orange, m. 275° (decompn.); the filtrate gives 1.2 g. of *3-nitro-2-acetoxy-1-acetyl-2,3-dihydroindeno(2',3',2,3)indole*, m. 177–80° (decompn.); this is an addn. compd. formed by the attachment of NO_2 and OAc; I thereby exhibits reactivity which is abnormal in an indole of this degree of complexity. II did not show a similar behavior. β-Hydrindone (IV) and *p*-$O_2NC_6H_4NHNH_2$ in EtOH give the hydrazone, yellow, m. 232° (decompn.); refluxing with AcOH-HCl gives *5-nitroindeno(2',3',2,3)-indole*, crimson, m. 255°; *1-Ac* deriv., yellow, m. 247°, which is not the same as III. IV yields a *β-naphthylhydrazone*, yellow, m. 176° (decompn.); boiling with AcOH for 5 min. gives *indeno(2',3',2,1)-β-naphthindole*, yellow, m. 208–9°; *3-Ac deriv.*, m. 185°; HNO_3 in AcOH does not give an addn. compd. but the *?-NO_2 deriv.*, yellow, m. 265° (decompn.); the results indicate that the ability to form addn. compds. is diminished by the presence of the addnl. benzene nucleus. C. J. West

Mechanism of indoxyl formation in vivo from certain *o*-nitrophenyl derivatives. F. Böhm. *Z. physiol. Chem.* **261**, 35–42(1939); cf. *C. A.* **33**, 7898⁴.—Feeding *o*-$NO_2C_6H_4C{:}CCO_2H$ (I) to rabbits results in the excretion of small amts. of *o*-$NO_2C_6H_4CO_2H$ (II) and with large toxic doses *o*-$NO_2C_6H_4CH_2CH(OH)CO_2H$ in addn. to the previously recognized indican formation. The Et ester of I gives II besides indican. The mechanism proposed by Crowdle and Sherwin (*C. A.* **17**, 2443) for the formation of indoxyl from I *in vivo* is probably incorrect because the proposed intermediates, *o*-$NH_2C_6H_4CH{:}CHCO_2H$ and indole-α-carboxylic acid, do not produce an increase in indican excretion nor does *o*-$NH_2C_6H_4C{:}CCO_2H$. The last yields *o*-$NH_2C_6H_4CO_2H$ in the urine. A new mechanism is proposed as follows: I → *o*-$NO_2C_6H_4C(OH)CHCO_2H$ (III) → *o*-$NO_2C_6H_4COCH_2CO_2H$ (IV) → II or *o*-$HONHC_6H_4COCH_2$-CO_2H which then loses H_2O between NHOH and CH and CO_2 to give indoxyl. While the intermediates III and IV were not available, it is shown that *o*-$NO_2C_6H_4COCH_2$-$COCH_2CO_2Et$ does form small amts. of indican when fed. M. L.

***cis*-Indigo. II.** Gustav Heller. *Ber.* **72B**, 1858–60 (1939); cf. *C. A.* **30**, 4495⁴.—As had already been pointed out, the only known form of indigo is the trans modification, but from the behavior of dyed fibers it can be concluded that the cis form is primarily deposited on the fiber and converted into the trans form in the subsequent operations. The cis modification should be formed, if at all, by shaking the vat with air at room temp. A product (I) so obtained was, in paste form, dark blue with violet tinge, considerably deeper in color than the product (II) obtained on the water bath. Soly. expts. showed the cis form (I) is extraordinarily unstable but in some solvents there can be observed, now and then, a momentarily stronger color which, corresponding to the soly. of the trans form, immediately becomes weaker. The primary color is distinctly and reliably reproducible in dioxane, in which it is stable for some time. I behaves in the same way in CCl_3CO_2H, but not so distinctly and is not so stable; the color is stronger than in AcOH. A difference between I and II is also noted in a mixt. of 87.5 parts AcOH and 12.5 parts H_2SO_4, which gives a blue color, not the green of H_2SO_4 solns. (sulfonation). On shaking I and II with this mixt. I apparently dissolves while II hardly gives any color; the difference persists about 0.5 hr. and then gradually disappears as the I changes into II. The instability of I is further shown by the fact that the above differences are no longer observed 24 hrs. after the pastes of I and II have been dried. That in reactions, such as the formation of oxalylindigo from indigo, the reverse change of the trans into the cis form occurs has by no means been proved as yet. From the statement of Thiele and Pickard (*Ber.* **31**, 1252(1898)) that indigo oxime cannot be prepd. from indigo powder and NaOH with NH_2OH but only from the dye in a very fine state of subdivision, as obtained from the vat, it might be concluded that this is a reaction of the cis compd., but their statement is erroneous. The oxime is best obtained by covering indigo powder or paste with dil. NaOH and NH_2OH salt solns., filling the flask almost full, covering it with a watch glass, heating 0.5 hr. on the water bath and filtering into dil. HCl. If somewhat stronger alkali is used it may happen that at first nothing is pptd.; apparently this is due to the formation of a difficultly sol. Na salt, and on washing the substance on the filter dissolves. C. A. R.

Cyclotetramethylenepyrazolone. II. Hans Ruhkopf. *Ber.* **72B**, 1978–82(1939); cf. *C. A.* **31**, 4978⁸.—In part I was reported the prepn. of new derivs. of 3,4-cyclotetramethylene-5-pyrazolone (I) which are exceptionally well adapted to therapeutical application. It was found that condensation of Et cyclohexanone-2-carboxylate (II) with $PhNHNH_2$ in the cold does not result directly in closure of the ring but stops at the phenylhydrazone stage, and further reaction, with elimination of alc., occurs only on heating. To obtain light on the conditions under which simple hydrazone formation or pyrazolone ring closure occurs, a study was made first of the influence of substituents in position 1. When II was allowed to stand 12 hrs. with the hydrazine in cold dioxane the pyrazolone was formed directly in all cases where the phenylhydrazine had 1 substituent on the ring. With the 2,4-dinitro compd. condensation, even with heat, stops at the *hydrazone* (60% yield), yellow, m. 156°, which does not form the pyrazolone when fused. With β-$C_{10}H_7NHNH_2$ (which may be regarded as a 3,4-disubstituted $PhNHNH_2$) ring closure again occurs directly with elimination of water and alc. With α-$C_{10}H_7NHNH_2$ (2,3-disubstituted $PhNHNH_2$) the results are still doubtful. There is apparently first formed a relatively stable hydrazone which, on recrystn., undergoes ring closure. These results allow as yet of no definite conclusions on the tendency to ring closure; possibly a 2nd substituent, in addn. to one in the 2-position, makes ring closure more difficult. Halogens with derivs. of I form dihalides which, however, are just as unstable as those of monocyclic pyrazolones. Under the influence of water they readily form monosubstitution products with elimination of halogen acid. As the halogen adds at the double bond, tautomerism allows of various possible positions for the halogens. With the 1-Ph compd. these positions have been established. If Br added at the 2,3-positions elimination of 1 mol. HBr would give a 2-Br deriv., with no adjacent H atom permitting elimination of a 2nd mol. of HBr, and since even very weak bases, like $NHEt_2$, actually do eliminate a 2nd mol. of HBr to give a halogen-free product (III) the addn. of Br must have occurred at the 3,4-positions and the mono-Br compd. (IV) is the 4-Br deriv. As easy, however, as it is to split out 2 mols. HBr, it is just as difficult to obtain the III in pure form. When 5 g. IV is boiled in 100 cc. MeOH with 5 cc. of 10% NH_4OH (or the corresponding amt. of $NHEt_2$) it yields 20–5% of a cryst. *compd.*, $C_{26}H_{26}O_2N_4$, m. 174° (decompn.), mol. wt. in camphor 426, together with a viscous, Br-contg. sirup which resists all further treatment. The Et cyclohexen-6-one-1-carboxylate, b_{760} 220°, obtained in 30% yield by bromination of II (Kötz, *C. A.* **2**, 1276), gives with $PhNHNH_2$ in alc. the same sirup, from which up to 20% of the above cryst. compd. can also be isolated. The other monohalogen derivs. of I, unsubstituted or completely substituted at positions 1 and 2, also very probably have the halogen at position 4, although position 3 is not excluded. Only 1 dihalogen deriv. has thus far been obtained. The halogen derivs. no longer have the power to form mol. compds. with substituted barbituric acids. Their antipyretic action is materially higher than that of the halogen-free compds., their toxicity is greater and they are all highly irritating to the mucous membranes. *Derivs.* of I: *1-o-tolyl* (80% from 12.2 g. *o*-tolylhydrazine in 100 cc. dioxane and 15.4 g. II allowed to stand 12 hrs.), yellowish white, m. 184°; *1-m-tolyl* (80%), ivory-colored, m. 149.5°; *1-p-tolyl* (80%) m. 203°; *1-(4-nitrophenyl)* (90%), yellow, m. 236°; *1-β-naphthyl* (80%), light brown, m. 180°; *4-Br* (75% from 13.6 g. I in 50 cc. AcOH treated with stirring with 16 g. Br in 50 cc. AcOH and after 1 hr. poured into 300 cc. ice water), m. 133°; *1-phenyl-4-bromo* (95% from the 1-Ph deriv.), light yellow, m. 85°; *1-p-tolyl-4-bromo* (80%),

deep yellow, m. 94°; *4-Cl* (60%), m. 112°; *1-phenyl-4-chloro* (90%), m. 70°; *2-methyl-1-phenyl-3,4-dichloro* (60% from 22.8 g. of the Cl-free pyrazolone in 100 cc. $CHCl_3$ treated with 7.1 g. Cl), m. 183° (decompn.). *4-Bromo-2-methyl-1-phenyl-Δ6′-tetrahydrobenzo(1′,2′,3,4)-pyrazol-5-one*,  (90% from the Br-free pyrazolone with Br in AcOH), m. 138° 1



C. A. R. 2

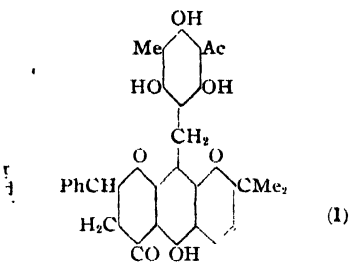
Benzisoxazoles. III. Walther Borsche and Wilhelm Scriba. *Ann.* **541**, 283-92(1939); cf. *C. A.* **33**, 8197⁶.—Meyer (Cathcart and M., *Ber.* **25**, 3291(1892)) was of the opinion that benzisoxazoles could not be prepd. from oximes of *o*-acylated halo- or nitrobenzenes unless the radical $XC_6H_4C(:NOH)$ is bound with a neg. group. It is now shown that this is not true. *o*-BrC_6H_4CN and MeMgI give 85% of 2-BrC_6H_4Ac, b_{16} 118-20°; *oxime* (I), m. 129°. 2-$BrC_6H_4CO_2Me$ and MeMgI give some *dimethyl-2-bromophenylcarbinol*, b_{16} 128-30°; BrC_6H_4Ac was not formed. Heating I with KOH in 50% MeOH gives 80% of 3-methylbenzisoxazole, b_{15} 104-8°. *o*-BrC_6H_4CN and EtMgBr give 90% of 2-bromopropiophenone, yellowish oil, b_{16} 135-40°; *2,4-dinitrophenylhydrazone*, orange-yellow, m. 115-16°; *oxime*, b_{16} 164-72°; with KOH in 50% MeOH (9 hrs. at 120°) there results a mixt. of unchanged oxime and ethylindoxazene. *o*-BrC_6H_4CN (18.2 g.) and $PhCH_2MgCl$ give about 12 g. of 2-bromophenyl benzyl ketone, b_{15} 206-8° (*2,4-dinitrophenylhydrazone*, orange, m. 149°; *oxime*, m. 116°); KOH in 50% MeOH (8 hrs. at 110-15°) gives 85% of *3-benzylbenzisoxazole*, m. 87°. 4,3-$Br(H_2N)C_6H_3Me$ gives about 70% of *3-cyano-4-bromotoluene*, m. 65°; MeMgI gives *3-acetyl-4-bromotoluene*, b_{15} 132-6°; *2,4-dinitrophenylhydrazone*, orange, m. 170°; *oxime*, m. 131-2° (cf. Claus, *J. prakt. Chem.* **46**, 26(1892), who states that it could not be converted to II); KOH in 50% MeOH (9 hrs. at 150°) gives 3,5-dimethylbenzisoxazole (II), b_{14} 116-18° (NO_2 deriv., m. 72°). 2,4-$Cl_2C_6H_3CN$ (6.4 g.) gives 4 g. 2-ClC_6H_4Ac; *2,4-dinitrophenylhydrazone*, dark yellow, m. 206°; semicarbazone, m. 178-9°. 2-BrC_6H_4Ac, B_2H and 10% NaOH in MeOH give *2-cinnamoylbromobenzene*, b_{14} 234-8°, as a yellow, viscous oil; *2,4-dinitrophenylhydrazone*, red, m. 236-7°; an oxime could not be prepd. 6,3-Br $(O_2N)C_6H_3Ac$ (4.88 g.) and 4 g. $PhNHNH_2.HCl$ in MeOH, heated 18 hrs. at 150°, give 3.1 g. of *3-methyl-1-phenyl-5-nitroisoindazole*, yellow, m. 131-2°; catalytic reduction gives the *5-NH₂ deriv.*, m. 127-8° (*Bz deriv.*, m. 160-1°); a by-product, yellow, m. 336°, is probably the corresponding *azoxy compd.* Removal of the NH_2 group gives *3-methyl-1-phenylisoindazole*, m. 73-4°. 3

C. J. West

Antisterility factors (vitamin E). VII. Red oxidation products of tocopherol. W. John and W. Emte. *Z. physiol. Chem.* **261**, 24-34(1939); cf. *C. A.* **33**, 2896². Oxidation of α-tocopherol with $AgNO_3$ in boiling EtOH gives *α-tocopherol red* (I) $C_{58}H_{92}O_6$, oily, max. ultraviolet absorption at 270 mμ, in max. yield after 100-120 min I is a quinone, reducible by H, and on reductive acetylation gives an oily *diacetate*, $C_{32}H_{52}O_5$. β-Tocopherol similarly yields *β-tocopherol red* (II). Both I and II are bimol. 4

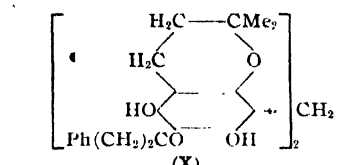
nplds. Analogous oxidation of tetramethylhydroxychroman gave a *chroman red 141*, $C_{12}H_{14}O_3$ (IV in Karrer, Fritzsche and Escher, *C. A.* **33**, 6310²) and a 2nd product, $C_{11}H_{10}O_4$ (III), m. 145°. IV takes up H and the product is autoxidizable. It is converted to a light-yellow compd. by NaOH. Reductive acetylation gave IV *diacetate*, $C_{16}H_{20}O_5$, m. 82°. IV is assigned the structure 5

and probably exists as a dimer. Reductive acetylation of chroman red 109, obtained by oxidation of pentamethylhydroxychroman, gave a *diacetate*, m. 91°. In III, the Me group at 7 has been replaced by OH. Similar oxidation at 8 should yield a diquinone. Reductive acetylation of III yields a *diacetate*, $C_{15}H_{18}O_6$, m. 116°, instead of the expected triacetate. The structures of I and II are probably analogous to that of IV. Over-oxidation of IV by HNO_3 until the color is completely yellow gives a *product*, m. 129°, which is isomeric with IV. 6



Milton Levy

Rottlerin. II. Hans Brockmann and Karl Maier. *Ann.* **541**, 53-75(1939); cf. *C. A.* **32**, 8419⁷.—Isorottlerin (I) (960 mg.) in 5 cc. Me_2CO and 1 g. K_2CO_3, warmed 0.5 hr. on the water bath, give 790 mg. of *pseudorottlerin* (II), m. 193-4°; 2 *N* NaOH gives BzH; $FeCl_3$ gives a green-brown, and H_2SO_4 a reddish brown, color; boiling 230 mg. of II with 6 cc. AcOH for 70 min. gives 175 mg. I. II (420 mg.) and Ac_2O in C_5H_5N give 500 mg. of the *pentaacetate* (IIA), yellow, m. 176-7.5°; reduction gives an oily product. The dihydro deriv. (III) of I, warmed 1 hr. with K_2CO_3 in Me_2CO, gives *dihydropseudorottlerin* (IV), yellow, m. 206-7°; in 1 expt. a product m. 215-16° was obtained; boiling AcOH (1 hr.) gives III. The *pentaacetate* (IVA) of IV, pale yellow, m. 181-2.5°. Catalytic reduction of II, III or IV in Me_2CO with Pd black or of I in Me_2CO contg. K_2CO_3 gives *tetrahydropseudorottlerin* (V), m. 225-6°; $FeCl_3$ gives a gray-green, H_2SO_4 a yellow, color; the reduction of I without K_2CO_3 usually gives IV; in 2 expts. the principal product was V. I (800 mg.), 3 cc. Me_2SO_4, 6 g. K_2CO_3 and 30 cc. Me_2CO give 530 mg. of the *penta-Me ether* (VI) of II, pale yellow, m. 135-6°; this is not hydrolyzed by refluxing with EtOH-H_2SO_4. III, Me_2SO_4, K_2CO_3 and Me_2CO give a *penta-Me ether* (VII) of IV, pale yellow, m. 134°. Catalytic reduction of VI in Me_2CO contg. a trace of C_5H_5N with Pd black gives a *penta-Me ether* (VIII) of IV, m. 123-4°. Rottlerin penta-Me ether gives a *dihydro deriv.* (IX), m. 86-7°. V yields a *tetra-Me deriv.*, m. 154-6°, and from the MeOH-Me_2CO mother liquor a *penta-Me deriv.* (X), m. 98°; the latter also results from the reduction of VI, VII or VIII. The action of O_3 upon II, IV, VI or VII gives BzH but IX gives no volatile fraction. II and PhN·NHPh in Me_2CO give the same azo dye, $C_{30}H_{27}O_6N_2Ph$, m. 201-4°, as rottlerin; IV and V give the same dye as does tetrahydrorottlerin (XI). V and 2 *N* NaOH warmed to 65°, give *tetrahydropseudorottlerone* (XII), $C_{20}H_{22}O_4$ or $C_{21}H_{24}O_4$, m. 179°; B_2O_3 in Ac_2O gives an intense citron-yellow color; *di-Me ether*, m. 87-9°. Absorption spectra are given for II, IIA, III, IV, V, VI, VII, VIII, X, XI, XII and rottlerin penta-Me ether. Structural formulas are suggested for I, II, III, IV and V. 7



C. J. West

Rottlerin. IV. Alexander McGookin, Alexander Robertson and Eric Tittensor. *J. Chem. Soc.* **1939**, 1579-87; cf. *C. A.* **34**, 104⁴.—The fact that neither 5,7-dihydroxy-6- nor 5,7-dihydroxy-8-β-phenylpropionylchroman (I) is identical with octahydrorottlerone (II) (part III), referred to in parts I and II (*C. A.* **31**, 5359²; **32**, 4555⁴) as tetrahydrorottlerone (III), led to a reinvestigation of this substance. While fission of II with hot concd. alkali gives results identical with those previously recorded (part II), the use of more dil. alkali has now been found to yield I. This behavior, and the absence of *C*-methylphloroglucinol derivs. in the hydrolyzate, together with the conversion of II into *2,4,6,2′,4′,6′-hexahydroxy-5,5′-diacetyl-3,3′-dimethyldiphenylmethane* (IV) and II, suggested that the latter had the structure type of *7′-tetrahydroxy-8,8′-diacetyl-2,2,2′,2′-tetramethyl-6,6′-dichromanylmethane* (V), which is in good agreement with the analytical results of the substance and its derivs. This conclusion is confirmed by the synthesis of II from the 2,2-di-Me deriv. of I and HCHO. The structure of IV, which was arrived at by analysis and degradation, was also confirmed by its synthesis. Reinvestigation of a considerable no. of rottlerin (VI) derivs. did not serve to distinguish between the empirical formulas $C_{30}H_{28}O_8$ and $C_{31}H_{30}O_8$ for VI but the results of mol.-wt. detns. appear to exclude formulas based on C_{60} or C_{62}, which might be expected on the basis of the simultaneous formation of IV and V from III. The isolation of 2,4,6-trihydroxy-5-acetyl-3-methylazobenzene (VII) from the latter by Bochm's reaction confirms the presence of the *C*-methylphloroacetophenone (VIIA) residue in VI. The residue is joined to the rest of the mol. by a CH_2 group. Consideration of all 8 9

the available evidence disproves the view that VI contains a lactone group. **VI** m. 212° (unchanged after 4 years); penta-Ac deriv., m. 213°; **VI** and Me_2SO_4 with K_2CO_3 in boiling Me_2CO give the *O*-penta-Me deriv. (**VIII**), m. 142°; CH_2N_2 gives the di-Me deriv. (**IX**), m. 254°. Tetrahydrorottlerin (**X**) m. 215° and yields a penta-Me deriv., m. 109°, which also results in a quant. yield by catalytic reduction of **VIIII**; CH_2N_2 gives the *O*-di-Me deriv., pale greenish yellow, m. 192° (also prepd. by reduction of **IX**), and what appears to be the *tri-Me deriv.*, bright yellow, m. 153°. **X** and PhN·NNHPh in boiling EtOH give **VII**, red plates, m. 202°; this also results from **VI**. Rottlerone and Me_2SO_4 give the *tetra-Me ether*, pale yellow, m. 136°. **II**, $C_{31}H_{44}O_8$, m. 173°; tetra-Ac deriv., m. 215°; tetra-Me ether, m. 102° (dioxime, m. 204.5°). **X** (2 g.) in 90 cc. AcOH and 10 cc. H_2O, refluxed 12 hrs., gives 0.47 g. **IV**, light yellow, m. 291° (decompn.), which yields a red-brown color with EtOH-$FeCl_3$; the mother liquor yields 0.83 g. of **II**. **IV** and Me_2SO_4 give the *hexa-Me ether*, m. 103°; **IV** and PhN·NNHPh give **VII**. **II** and 20% aq. NaOH in EtOH, with or without Zn in N (heated 3 hrs.), give **I**, $PhCH_2CH_2$-CO_2H and 5,7-dihydroxy-2,2-dimethylchroman (**XI**), m. 162°. **XI** and PhN·NNHPh yield a bis(phenylazo) deriv., bright red, m. 256° (decompn.). 5,7-Dihydroxy-8-acetyl-2,2-dimethylchroman and 40% aq. HCHO with H_2SO_4 in EtOH give **V**, yellow, m. 240°; $FeCl_3$ gives an intense rich-purple color. The 2,2-di-Me deriv. of **I** and 40% HCHO with H_2SO_4 in EtOH give **II**. **VIIA** and HCHO give **IV**. In the prepn. of perhydrorottlerin Me_2CO, AcOH or AcOEt as solvents gave unsatisfactory results; with EtOH the variety m. 188° occurs much less frequently than that m. 182°; with PhN·NNHPh both forms give **VII** and they give the same perhydrorottlerone, m. 147°; from EtOH or AcOEt a labile form, m. 159–60°, may be occasionally obtained **V** **Tetrahydroallorottlerin**. *Ibid.* 1587–93. Isorottlerin (**I**), $C_{30}H_{28}O_8$, catalytically reduced by Pd-C in AcOH or AcOEt at 10 lb./sq. in. during 2 hrs., gives the *dihydro deriv.* (**II**), light yellow, m. 213°; reduction with Pd-C in EtOH, Me_2CO or AcOEt at 5 lb./sq. in. during 2 hrs. gives *tetrahydroallorottlerin* (**III**), bright yellow, m. 241°, which gives a brown $FeCl_3$ reaction in EtOH; **III** also results from **II** under the same conditions. At atm. pressure there results a mixt. of **II** and **III**, sepd. in part by crystn. from Me_2CO. **I** and Me_2SO_4 with K_2CO_3 in Me_2CO give the *O-penta-Me ether*, pale greenish yellow, m. 136°; catalytic reduction with Pd-C in abs. EtOH at 20 lb./sq. in. gives *O-pentamethyltetrahydroallorottlerin* (**V**), m. 101°; this also results from **III** and Me_2SO_4. **II** and Me_2SO_4 with K_2CO_3 in Me_2CO give a mixt. of a *tetra-Me ether* (**VI**), m. 149°, and a *penta-Me ether* (**VII**), pale greenish yellow, m. 135°. **VI** is not further reduced but **VII** gives **V**. **III** and PhN·NNHPh in EtOH give a mixt. of 2,4,6-trihydroxy-5-acetyl-3-methylazobenzene, m. 202°, and *8-phenylazo-5,7-dihydroxy-6-β-phenylpropionyl-2,2-dimethylchroman* (**VIII**), orange-red, m. 162°; the last was also prepd. from 5,7-dihydroxy-6-β-phenylpropionyl-2,2-dimethylchroman (**IX**) and PhN·NNHPh. The 8-β-phenylpropionyl isomer of **IX** and PhN·NNHPh give the *6-phenylazo isomer* of **VIII**, dark red, m. 181°. 5,7-Dihydroxy-8-acetyl-2,2-dimethylchroman gives a *6-phenylazo deriv.*, deep red, m. 232°. **III** (1.8 g.) in 75 cc. of 4% aq. NaOH in N, heated to 55° for 5 min. and rapidly cooled, gives 0.6 g. of *octahydroallorottlerone* (**X**), pale yellow, m. 175–5.5°; *tetra-Ac deriv.*, m. 163°. **X** and PhN·NNHPh in EtOH-dioxane, heated on the steam bath for 0.5 hr., give **VIII**. **III** in AcOH (boiled 12 hrs.) gives 2,4,6,2′,4′,6′-hexahydroxy-5,5′-diacetyl-3,3′-dimethyldiphenylmethane, m. 291°, and **X**. 5,7-Dihydroxy-6-β-phenylpropionyl-2,2-dimethylchroman and 40% HCHO with H_2SO_4 in EtOH give **X**. 5,7-Dihydroxy-6-acetyl-2,2-dimethylchroman gives 5,7,5′,7′-tetrahydroxy-6,6′-diacetyl-2,2′,2′-tetramethyl-8,8′-dichromanylmethane, greenish yellow, m. 209°, which gives a dark purple-brown $FeCl_3$ reaction. The conversion of rottlerin into **III** by way of **I** is explained and the structure which has been deduced for the latter compd. is supported by its behavior on hydrogenation and methylation. The relationship of the ethers obtained from **I** and its hydrogenation products has been detd. and their orientation established.

Yellow pigment of Papaver nudicaule. I. I. R. Price, Robert Robinson and R. Scott-Monerieu (mrs. Meares). *J. Chem. Soc.* **1939**, 1465–8(1939).—Details are given of the isolation of *nudicaulin chloride* (**I**), $C_{30}H_{35}O_{15}NCl \cdot 4H_2O$, from the flowers of *Papaver nudicaule*. **I** is a yellow to orange-yellow, amorphous powder, contg. 0.3 MeO group. It forms an orange-yellow Pb salt and a bright-red Hg salt. Hydrolysis affords about 40% of glucose (calcd. for a diglucoside, 52.8%); the other product is a reddish brown solid, which is in part a condensation product; the ratio of N:Cl is 1:0.75, as in **I**. Methylation and oxidation give anisic acid and thus **I** contains a *p*-HOC_6H_4 grouping. KOH fusion and methylation of the acid fraction also yield this acid. The behavior with HNO_2 indicates the presence of a NH_2 group. An aliphatic aldehyde appears to be formed on oxidation with H_2O_2. **I** is not extd. from an aq. soln. by BuOH or iso-AmOH even in the presence of NaCl but if the liquid is neutralized there is partial extn. of the colorless ψ-base, which is the chief reason for suspecting the presence of a flavylium salt structure but this is not decisive. The buds of yellow Iceland poppies, which are red, contain a pelargonidin diglucoside or bioside; this disappears as the flower develops.

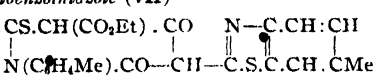
Synthetical experiments in the flavone and isoflavone groups. R. Venkataraman. *Proc. Natl. Inst. Sci. India* **5**, 253–60(1939).—A general survey. C. J. West

Synthesis of some naturally occurring flavones from chalcones. T. S. Wheeler. *Proc. Natl. Inst. Sci. India* **5**, 267–74(1939).—A general survey. C. J. West

Vitexin. Ervin Péteri. *J. Chem. Soc.* **1939**, 1635–7.—Vitexin (**I**) was isolated by Perkin (*J. Chem. Soc.* **73**, 1019 (1898); **77**, 416(1900)) from New Zealand dyewood (*Vitex littoralis*) and by Barger (*J. Chem. Soc.* **89**, 1210 (1906)) from *Saponaria officinalis*. P. assigned the formula $C_{16}H_{14}O_7$ or $C_{17}H_{16}O_8$ to **I**. **I** isolated by P.'s method has the formula $C_{16}H_{14}O_7$ and m. 263°; it yields a *penta-Ac deriv.*, m. 251–6°. Attempts to convert **I** to apigenin ($C_{15}H_{10}O_5$) by dehydrating agents failed. Oxidation with H_2O_2 gives *p*-$HOC_6H_4CO_2H$ (**II**) and a minute quantity of quinol; Fehling soln. gives 1,3,5-$C_6H_3(OH)_3$, *p*-HOC_6H_4Ac and an amorphous acid; $K_3Fe(CN)_6$ gives **II**. **I** reduces a large amt. of $AgNO_3$-NH_4OH but the oxidation product could not be isolated; it does not react with $Pb(OAc)_4$ in AcOH, possibly owing to its insoly. **I** does not yield cryst. compds. with the usual methylating agents. Nitration of **I** and crystn. from dioxane gives the tetra-NO_2 deriv., yellow, m. 257°, which does not depress the m. p. of tetranitroapigenin. Sublimation of **I** with Zn dust at 350–60° gives a compd. $C_{18}H_{12}O_6$, the Ac deriv. of which does not depress that of triacetylapigenin (m. 181–2°).

C. J. West



Demethylation of wogonin. Sizuo Hattori. *Ber.* **72B**, 1914–17(1939).—Although H. had always obtained 5,7,8-trihydroxyflavone (I) by demethylation of wogonin (5,7-dihydroxy-8-methoxyflavone) (II), Shah, Mehta and Wheeler (*C. A.* **33**, 601[8]) report the formation, from 7-hydroxy-5,8-dimethoxyflavone, of the 5,6,8-tri-HO compd. (baicalein) (III) with HI, and normal demethylation (formation of II or I, depending on the amt. of reagent), on heating with anhyd. $AlCl_3$. They conclude that in the treatment with HI the γ-pyrone ring is opened and subsequently reclosed in the opposite direction. Other cases where hydroxymethoxylflavones of the 5,7,8-type undergo the one or the other kind of demethylation are reported in the literature. It was suspected that differences in the exptl. conditions might be responsible for the apparent discrepancies and H. accordingly undertook a study of the conditions under which rearrangement will or will not occur. When II is very gently boiled a short time (5 min. at most) or heated 30 min. at 130–5° with 15–20 parts of HI of d. 1.7 (either freshly prepd. and colorless or brown from liberated I), it gives chiefly I, also obtained with the S., M. and W. mixt. of equal parts HI (d. 1.7) and Ac_2O on short gentle boiling as above. When, however, II is heated in this mixt. in an oil bath preheated to 145–50° or 150–5°, the product is III; in 1 expt. in which the temp. did not rise above 140°, some I was also obtained. Similar results were obtained with HI alone. Attempts to rearrange I into III by vigorous boiling with HI with or without Ac_2O were unsuccessful. The conclusion which might be drawn from the observations of S., M. and W. that demethylation of these hydroxyflavone Me ethers with HI is always accompanied by opening of the ring and its reclosing in the opposite direction must be qualified. I, deep yellow, m. 250–1° (previously reported as 227–8°), gives with alc. $FeCl_3$ a brown color and, after standing overnight, deposits a deep-brown cryst. ppt. When moistened with 5% NaOH, it transiently becomes brownish red and then dissolves with a light red-brown color. III, m. 263°, on the other hand gives with alc. $FeCl_3$ a dark olive-black color and on standing deposits a ppt. of the same color. In 5% NaOH it dissolves at once with brown-red color quickly changing to dark olive-blue with formation of a fine, dark-blue ppt.; in more dil. NaOH it dissolves with grass-green color, quite rapidly changing through light green to yellow. Mixed m. p. with I, about 235°. Cf. *C. A.* 25, 1595. C. A. R.

Cleavage of heterocyclic compounds of coal tar. (Correction of the communication under the same title by R. Weissgerber and Chr. Seidler.) O. Kruber. *Ber.* **72B**, 1878 (1939). The statement of W. and S. (*C. A.* 22, 416) that diphenylene oxide (I) is stable toward alkali at 300° and higher is erroneous, for as W. had himself already shown with Kramer (*Ber.* **34**, 1662[1901]); Ger. pat. 130,679) I at about 250° is cleaved to $(o\text{-}HOC_6H_4)_2$, and the cleavage of homologs of I and its 2,3-benzo deriv. has been effected (K., *C. A.* **31**, 6655[9]). This correction is made because it is being sought to utilize the erroneous statement in patent litigation. C. A. R.

Condensation of arsenic halides with pyridine and quinoline hydrohalides. P. P. Popov. *J. Gen. Chem.* (U. S. S. R.) **9**, 1265–73(1939).—The complexes formed may be divided into 5 types: $5RHX.2MX_3$, $2RHX.MX_3$, $3RHX.2MX_3$, $RHX.MX_3$ and $RHX.2MX_3$ (R = C_5H_5N or C_9H_7N, X = Cl, Br or I and M = As). $AsCl_3$ (I) (10.82 g.) in 100 cc. $CHCl_3$ (II) with 5.90 g. $C_5H_5N.HCl$ in 75 cc. II gave $2C_5H_5NHCl.AsCl_3.CHCl_3$. $AsBr_3$ (III) (8.00 g.) with 3.80 g. C_5H_5NHBr (IV) in II gave **IV.III**, which recrystd. from hot II gave **3IV.2III.II** (V), needles, and this on standing gave **2IV.III.II** (VI), yellow, also obtained directly from 6.80 g. IV and 6.60 g. III. VI dried in a vacuum at 60–5° gave **2IV.III**, pale yellow. V under the same conditions underwent only partial loss of II. VI in boiling benzene for 20 min. gave **5IV.2III** (VII), also obtained from 6.58 g. IV and 2.14 g. III in II by refluxing the mixt. for 10 min. VII heated with a large excess of II for 10 min. and allowed to stand several days gave VI. $C_5H_5N.HI$ (VIII) (0.288 g.) with 2.416 g. AsI_3 (IX) in II gave **VIII.IX** (**XI**), bright orange. Both **X** and **XI** are less hygroscopic than the extremely hygroscopic Cl- and Br-contg. complexes. I (5.5 g.) with 4.9 g. $C_9H_7N.HCl$ (**XII**) in II gave **XII.I**, extremely hygroscopic, m. 122–3°. III (4.6 g.) with 3.0 g. $C_9H_7N.HBr$ (**XIII**) gave **XIII.III**, yellow-green, hygroscopic, m. 147–8°. **IX** (1.20 g.) with 0.34 g. $C_9H_7N.HI$ (**XIV**) in II at 40–50° gave **XIV.2IX**, bright orange, decomps. with darkening when heated, which, refluxed with II for 30 min., gave **XIV.IX**, golden yellow. All of the complexes undergo decompn. when dissolved in water. John Livak

Nicotinic amide and nicotinic acid. V. Helweg Mikkelsen. *Arch. Pharm. Chem.* **46**, 479–97(1939)(German summary).—Methods of prepn. and purification are discussed and results compared. Otto Johnson

Action of *p*-tolyl isothiocyanate on ethyl acetonedicarboxylate. David E. Worrall. *J. Am. Chem. Soc.* **61**, 2966–9(1939).—Addn. of 1 equiv. of $CO(CH_2CO_2Et)_2$ (I) to 0.25 g.-mole of Na in Et_2O, followed by 1 equiv. of *p*-MeC_6H_4NCS (II) and decompn. of the product with cold dil. HCl gives *1-p-tolyl-2,4-dioxo-5-carbethoxy-6-thiopiperidine* (III), $OC.CH_2.CO.CH(CO_2Et).CS.NC_6H_4Me$, m. 174–5° (decompn.); the aq. Na_2CO_3 soln. of III is pptd. by HCl but not by AcOH; the alk. soln. neutralized with AcOH gives a blue-green ppt. with $FeCl_3$. III is gradually decompd. by heating with AcOH, slowly evolving H_2S (speeded up by the presence of $PhNHNH_2$) and giving amorphous products. Refluxing III with coned. EtOH-KOH gives *1-p-tolyl-2,4-dioxo-6-thiopiperidine*, gray powder, m. 158–9° (decompn.). III and excess MeI in warm MeOH give a ppt. of the *6-methylmercapto deriv.* (IV), m. above 250° (decompn.); no H_2S is evolved on heating with AcOH; it forms a sparingly sol. salt with NaOH. With Br in AcOH (heating on the water bath) III yields the *3-Br deriv.*, pale yellow, m. 238–9° (decompn.); the *3-Br deriv.* of IV m. 165.5–6.5° and appears to sep. with EtOH of crystn. Shaking III in NaOH with Me_2SO_4 gives *1-p-tolyl-2-oxo-4-methoxy-5-carbethoxy-6-methylmercaptopiperidine*, m. 166°, which is insol. in both Na_2CO_3 and NaOH and does not react with Br. I reacts slowly and incompletely with the 2nd equiv. of Na, even when heated; the decanted soln. reacts with 2 equivs. of II to give *1-p-tolyl-2,4-dioxo-5-carbethoxy-6-thiopiperidine-3-thioformo-p-toluidide* (V), $MeC_6H_4N.CS.CH(CO_2Et).CO.CH(CSNHC_6H_4Me).CO$, yellow, m. 182–4° (decompn.); NH_4OH gives an *NII₄ salt;* H_2S is evolved on long heating with AcOH. The cold coned. H_2SO_4 soln. develops a blue fluorescence on warming. Heating V with EtOH-KOH for 1 hr. gives *1-p-tolyl-2,4-dioxo-6-thiopiperidine-3-thioformo-p-toluidide*, pale yellow, m. 205–8° (decompn.). Refluxing V with MeI in MeOH gives the *6-methylmercapto deriv.* (VI), bright yellow, m. 151–2°; it is pptd. from Na_2CO_3 soln. by AcOH or HCl but does not evolve H_2S on heating with AcOH. Refluxing VI with coned. EtOH-KOH for 1 hr gives *1-p-tolyl-2,4-dioxo-3-carboxy-6-methylmercaptopiperidine-3-thioformo-p-toluidide*, yellow, m. 232–3° (decompn.). The Na deriv. of V (prepd. with dil. NaOH and the salt crystd. from H_2O) and MeI, heated at 100° for 2 hrs., give *1-p-tolyl-2-oxo-4-methoxy-6-methylmercaptopiperidine-3-thioformo-p-toluidide*, m. 153°. V and Me_2SO_4 in warm dil. NaOH give *1-p-tolyl-2-oxo-4-methoxy-6-methylmercaptopiperidine-3,5-dicarboxylate*, m. 177–8°; *p*-MeC_6H_4NHMe is also formed. Reaction of V with Br in warm AcOH proceeds with evolution of HBr and formation of *1-(1-p-tolyl-2,4-dioxo-5-carbethoxy-6-thiopiperidyl)-5-methylbenzothiazole* (VII)

m. above 300°; it is sol. in NH_4OH or coned. H_2SO_4, in the latter with a bluish fluorescence; heating with AcOH and $PhNHNH_2$ liberates H_2S. Soln. of VII in cold NH_4OH and pptn. with HCl gives the free *acid*, m. 260–1° (de-

compn.). With MeI in EtOH-NH_4OH VII gives the *6-methylmercapto deriv.*, pale yellow, m. 282–3° (decompn.); this does not react with Br or $PhNHNH_2$. C. J. West

Alkaloids of Datura alba Nees. Cheoa Sakul Pradisth and Alfredo C. Santos. *Univ. Philippines Nat. and Applied Sci. Bull.* **7**, 1-4(1939); cf. *C. A.* **33**, 5593⁸.—The seeds of *D. alba*, grown in the Philippines, contain chiefly hyoscine and very little hyoscyamine, whereas the pericarps, leaves and stems yield only the former. The plant is more similar to the *D. alba* cultivated in Germany than to that grown in Japan. C. R. Addinall

The bases of Stemona tuberosa Loureiro. VII, VIII. Tuberostemonine of the root of Stemona tuberosa Loureiro. 2. Heisaburo Kondo, Kohei Suzuki and Masakiti Satomi. *J. Pharm. Soc. Japan* **59**, 443-50(in German, 177-84)(1939); cf. *C. A.* **31**, 106².—Tuberostemonine perchlorate, $C_{22}H_{33}O_4N.HClO_4$, in 5% aq. NH_3 when shaken with ether gave tuberostemonine (I), $C_{22}H_{33}O_4N$, with 1 mol MeOH, $C_{22}H_{33}O_4N.MeOH$, m. 86–8°. The formula, $C_{19}H_{29}O_4N$, as given in the previous paper is now corrected as above. I contains 1 lactone linkage and is inactive toward $HONH_2$ and *p*-nitrophenylhydrazine. I does not contain MeO, NMe or methylenedioxy radicals. Of the 4 O atoms, 2 form a lactone linkage, but the nature of the other 2 is not known. I does not contain OH groups as reported in the previous paper. I and MeI gives a methiodide, $C_{23}H_{33}O_4N.MeI.H_2O$, m. 236–8°. The nature of N linkage is tertiary instead of secondary as reported previously. In general I resembles a compd., $C_{22}H_{33}O_4N$, obtained from *Stemona sessilifolia* by Schild (*C. A.* **30**, 2973⁵). He reported, however, the existence of a double linkage detected by hydrogenation, but the authors failed to show the existence of an unsatd. linkage. **Stemonidine. 4 (Supplement).** K. Suzuki. *Ibid.* 450–7(in German, 184–6).—The proposed structure of stemonidine (II) is as follows: $C_{19}H_{31}O_5N = C_{17}H_{28}O_2(:N)(OMe)(-CO.O-)$. II and alc. MeI gave a methiodide, decompg. 263°, while II and MeI gave a compd., $C_{19}H_{31}O_5N.MeI$, decompg. 248°. Oxidation of II with alk. $KMnO_4$, followed by treatment with MeI, gave a methiodide, $C_{19}H_{29}O_5N.MeI$, decompg. 235°. Oxidation of stemonidine-MeOH (prepd. from the above methiodide) with alk. $KMnO_4$ gave a compd. as the chloroaurate, $C_{19}H_{29}O_5NMeAuCl_4$, m. 158°. Oxidation of II with $KMnO_4$ in H_2SO_4 gave a compd., $C_{16}H_{24}O_5N$ (III), m. 208°, sol. in benzene, and $C_{11}H_{17}O_4N$ (IV), m. 202°, insol. in benzene. III does not contain a =CO radical. IV contains 1 MeO radical and forms a semicarbazone, m. 258°, but it cannot be acetylated. Dehydrogenation of II with Pd and asbestos gave a dehydro base, $C_{17}H_{23}O_4N$, contg. 1 each =N, lactone, —OMe, and perhaps =CO group. F. I. N.

Ether extract of the bark of Cajuput tree. Minoru Ishi and Yasuyosi Osima. *J. Agr. Chem. Soc. Japan* **15**, 841-2(1939).—The bark of *Melaleuca leucadendron* Linn. was extd. with ether. The yield of the ext. was 20%. When the unsaponifiable matter was extd. with petr. ether, cryst. scales, m. 79°, were isolated. The formula $C_{30}H_{50}O$ is given. The petr. ether-insol. part was again extd. with ether. Long needles, m. 215°, were obtained from the ext. From the residue a large amt. of needles, m. 304°, crystd. out after a day. They were insol. in petr. ether, difficultly sol. in alc. or ether, and sol. in hot alc. and showed the Liebermann reaction strikingly. They are given the formula $C_{28}H_{15}O_3$(?) and the name *melaleucin*. Mono-Ac deriv., m. 280°. Melaleucin is a new resinol. Y. Kihara

Chemical studies on the roots of Platycodon grandiflorum. VIII. Isolation, purification and properties of platycodigenin, a sapogenin. Magosaburo Tuzimoto and Ryoiti Senzyu. *J. Agr. Chem. Soc. Japan* **15**, 857-61 (1939); cf. *C. A.* **33**, 6448¹·³; **34**, 137⁵.—Platycodin, a saponin, (10 g.) in 500 cc. of abs. alc. was hydrolyzed by heating with 188 cc. of 20% HCl for 20 hrs., neutralized with NaOH, decolorized and evapd. Platycodigenin (I) sepd. as a yellowish brown mass. When it was dissolved in a little abs. alc. and 50% KOH was added, K platycodigenin crystd. out as colorless plates. I was isolated in a pure state from the K salt. It was also purified by the chromotographic method. It formed colorless needles or prisms, m. 242–3°, sol. in MeOH, EtOH, AcOH, Ac_2O and acetone, difficultly sol. in $CHCl_3$, insol. in H_2O, ether, C_6H_6 and petr. ether, $[\alpha]_D^{17}$ 59.45°. It is an unsatd. monobasic acid giving Liebermann's sterol reaction. It did not reduce Fehling soln. No MeO group in the mol. was proved. **IX. Determination of the molecular weight of platycodigenin.** *Ibid.* 862–4.—The mol. wt. of platycodigenin was detd. by the titration method, Barger's method and the elementary analysis of the K salt. The mean value was 527. The formula $C_{30}H_{48}O_7$ is given for platycodigenin. Also in *Bull. Agr. Chem. Soc. Japan* **15**, 132–3(1939)(in English). Y. K.

Chlorophyll. LXXXIX. Vinyl-, hydroxyethyl- and oxophylloporphyrins. Hans Fischer and Stewart Ferguson MacDonald. *Ann.* **540**, 211–23(1939); cf. *C. A.* **33**, 6336⁹.—Chlorine e_6 (I) (4 g.) in 25 cc. quinoline, heated 5 min. in a N atm. and poured into Et_2O, gives after extn. with 2–6% HCl, 600–700 mg. of phyllochlorine (II), extd. by 8% HCl; the Me ester m. 181°; the 2% HCl soln. contains 160 mg. of vinylphylloporphyrin (III), m. 238°, and the 0.5% HCl soln. from III contains phylloporphyrin (IV), whose ester m. 226°. I (1 g.) heated with 10% HCO_2H gives 30–40 mg. of III, whose ester m. 137°. Decarboxylation of 1 g. of I with Ph_2 (5 min.) gives about 0.5 g. of II and 100 mg. of III. Catalytic reduction of 50 mg. of III gives 7 mg. of IV; HI reduction gives a very poor yield of IV. The ester of II (2 g.) in 2 l. AcOH, treated with 25 cc. HI (d. 2; it is not necessary to decolorize the HI) and with a stream of air for 2–3 weeks, gives after methylation 370 mg. of the *Me ester* of *oxophylloporphyrin* (V), $C_{33}H_{36}N_4O_5$, m. 257°, acid no. 1.8; *Cu complex*, m. 278° (cor.); *oxime*, m. 290° (decompn., cor.). Hydrolysis of 165 mg. of V with 13.5 g. KOH in 22.5 cc. abs. EtOH (refluxing 5 hrs.) gives after methylation the *Me ester* of *2-desethyl-2-(α-hydroxyethyl)phylloporphyrin* (VI), m. 209–10°, acid no. 0.3; the Ac group is thus reduced to CH(OH)Me; VI also results in 18-mg. yield from 65 mg. of the ester of III in 7 cc. AcOH and HBr on standing 1 week; with HI in AcOH (3 weeks) III gives V; VI with HI in AcOH gives V in 1 week and in 24 hrs. with $KMnO_4$ in C_5H_5N. VI in $AcOH_{\text{v}}$ evapd. to dryness and heated on the water bath for 12 hrs., gives III; heating crystals of VI or smears from $CHCl_3$, Et_2O, Me_2CO or C_5H_5N causes no change. **XC. 2-α-Hydroxymesoisochlorine e_4 dimethyl ester and vinylisochloroporphyrin e_4.** Hans Fischer and Juan M. Ortiz-Velez. *Ibid.* 224–32.—The *hemin*, $C_{35}H_{38}N_4O_4FeCl$, from the di-Me ester (I) of isochlorine e_4 and $Fe(OAc)_2$ and NaCl in AcOH, does not yield satisfactory anal. results. The *hemin*, $C_{35}H_{40}N_4O_4FeCl$, from the di-Me ester (II) of mesoisochlorine e_4, m. 223°; the anal. results are satisfactory. II with $Cu(OAc)_2$ in $CHCl_3$-MeOH, heated 1 hr., gives the *Cu salt*, $C_{35}H_{40}N_4O_4Cu$, m. 125°. I (1 g.), shaken 1.5 hrs. with 50 g. HBr-AcOH, the AcOH removed at 45° and the residue hydrolyzed with 350 cc. 15% HCl at room temp. for 48 hrs., gives 790 mg. of the *di-Me ester* of *2-α-hydroxymesoisochlorine e_4* (III), brown, m. 170°; heating for 10 min. at 180° in a high vacuum gives I. Shaking 0.5 g. III in 40 cc. C_5H_5N with 2 g. $KMnO_4$ for 48 hrs. and esterification gives the *di-Me ester* of *2-acetylisochlorine e_4*, $C_{35}H_{40}N_4O_5$, orange, m. 243°. Isochlorine e_4 (200 mg.), 2 g. P_2O_5 and 10 g. sand, heated on the water bath, give pyropheophorbide a. II (200 mg.) in 50 cc. $CHCl_3$ and 10 cc. Br-AcOH, allowed to stand 24 hrs. and the perbromide decompd. with Me_2CO, gives the *di-Br deriv.*, m. 171° (*Cu complex*, green, m. 133°). I (100 mg.) in 20 cc. 80% HCO_2H, heated nearly to boiling, powd. Fe added and the mixt. warmed 2 min. on the water bath, gives 35 mg. of the *di-Me ester* of *vinylisochloroporphyrin e_4*, m. 224°; *Cu complex*, m. 221°; the *hemin*, orange, m. 278°. **XCI. Isopurpurins and neopurpurins.** Hans Fischer and Martin Strell. *Ibid.* 232–49.—The di-Me ether of neopurpurin 4 (I) gives a *Cu complex*, $C_{35}H_{34}O_4N_4Cu$, m. 245°. Dihydroxychlorine e_6 in C_5H_5N, refluxed 6 hrs. while O is passed through, gives after methylation the *di-Me ester* of dihydroxypurpurin 5 (II), removed by 13% HCl, which could not be crystd.; 14% HCl exts. dihy-

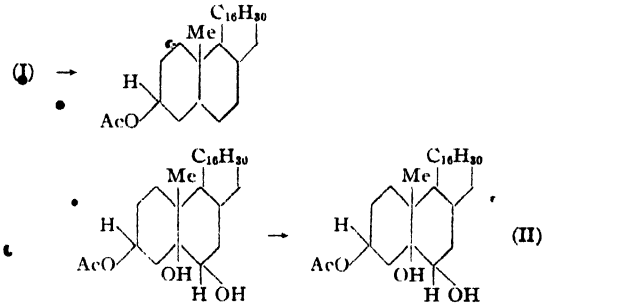
droxy-γ-hydroxymethylrhodochlorine lactone, m. 180°. II yields an oxime, which was not isolated. II in Et_2O contg. a little C_5H_5N, shaken 5 min. with 20% KOH-PrOH and esterified, gives the *Me ester* of *dihydroxyneopurpurin 4*, $C_{35}H_{36}O_6N_4$, m. 191°. Catalytic reduction of I in dioxane with Pd gives *mesoneopurpurin 4* (III), m. 200°. Shaking the di-Me ester of mesopurpurin 5 in EtOH contg. a little C_5H_5N with 25% KOH-PrOH for 5 min. also gives III. The di-Me ester of purpurin 5 (IV) in C_5H_5N, shaken with satd. MeOH-$Ba(OH)_2$, gives *"unstable" chlorine 5* (V), $C_{33}H_{34}O_6N_4$, m. above 300°; CH_2N_2 gives IV; V does not give the neopurpurin reaction; HI in AcOH gives chloroporphyrin e_5 lactone (VI). Shaking 600 mg. of IV in a little C_5H_5N with 300 cc. 5% MeOH-KOH for 1 min. gives 550 mg. of the *di-Me ester* of *isopurpurin 5* (VII), m. 210°; heating above the m. p. causes some decompn. but no other change; further action of 5% MeOH-KOH gives I and V; VII is unchanged by passing O through a boiling C_5H_5N soln. for 12 hrs.; with HI in AcOH VII yields VI. VII (50 mg.) in a little C_5H_5N, heated with 10 cc. 20% MeOH-KOH for 1–2 min. at 100°, gives the *mono-Me ester* of *2-vinylchloroporphyrin* e_5, m. above 300°; HI in HOH gives 2-ethylchloroporphyrin e_5. Catalytic reduction of VII in dioxane gives the *di-Me ester* of *mesoisopurpurin 5*, m. 183°. Hydrolysis of the ester gives *dihydroxypurpurin 5*, m. 175°. The tri-Me ester of purpurin 7 (200 mg.) with 4% MeOH-KOH (shaken 2 min.) gives 140 mg. of the *tri-Me ester* of *isopurpurin 7*, m. 270°; HI in AcOH gives pheoporphyrin a_7 di-Me ester. 10-Acetoxymethylpheophorbide a with CH_2N_2-MeOH gives a mixt. contg. chlorine e_7 lactone; MeOH-Na_2CO_3 (refluxed 2 hrs.) gives the ester of rhodochlorine, m. 208°.

XCII. Synthesis of rhodoporphyrin-γ-carboxylic anhydride and synthetic rhodines and verdins. Hans Fischer and Carl Gottfried Schröder. *Ibid.* **541**, 196–202.— Mesoverdin II ester in Me_2CO and powd. $KMnO_4$, shaken 1 hr. at 0°, give rhodoporphyrin-γ-carboxylic anhydride, m. 250°. Mesoporphyrin XIII (1,4-diethyl-2,3,5,8-tetramethylporphine-6,7-dipropionic acid) in the rhodine reaction gives *mesorhodine XIII*, $C_{36}H_{38}N_4O_3$, m. 275°; $H_2NNHCONH_2$.HCl gives *mesoverdin XIII*, $C_{35}H_{36}N_4O_3$, m. 241°. Mesoporphyrin II (di-Me 1,3,5,7-tetramethyl-4,8-diethylporphine-2,6-dipropionate) gives *mesorhodine II ester*, m. 240°, and *mesoverdin II ester*, m. 222–3°. Synthetic mesoporphyrin IX gives a mesorhodine and a mesoverdin identical with those previously prepd.; thus this compd. as isolated from the blood pigments must be considered homogeneous. C. J. West

The isolation and chemical constitution of bonelline, the green pigment of Bonellia viridis. Edgar Lederer. *Compt. rend.* **209**, 528–30(1939).—Pure bonelline (I) was obtained from cold alc. exts. of the gephyrean worm *Bonellia viridis* as follows. I was extd. with Et_2O from the residue after evapn. and extn. with petr. ether. From the Et_2O ext. I was extd. with 1% NH_4OH and then re-extd. with Et_2O after neutralization of the green alk. soln. I was then extd. with 6% HCl in which it gave a blue soln. After neutralization and reëxtn. by Et_2O the Et_2O soln. was passed through a column of $CaCO_3$, giving a wide green zone with some weak blue zones. I was eluted from the principal zone by soln. in dil. HCl and extd. with Et_2O. On evapn. a dark-green cryst. residue was left. I crystd. from Et_2O or toluene in fine needles which did not m. below 300° nor show fluorescence. Concd. solns. showed an intense red-green dichroism. I reacted with CH_2N_2 to form an ether salt which no longer had any acid characteristics. It formed complex salts with Cu, Fe and Zn. Only the Zn salt showed red fluorescence. The absorption and fluorescence spectra of I were strikingly similar to those of mesopyrrochlorine. The elementary analysis of I, C 69.76%, H 6.92% and N 10.4%, corresponded to the formula $C_{34}H_{36}N_4O_4 = H_2$. Rachel Brown

Constitution of the purine nucleosides. VIII. Uric acid riboside. Roderick Falconer and J. Masson Gulland. *J. Chem. Soc.* **1939**, 1369–71; cf. *C. A.* **32**, 5792[5].—Uric acid 9-*d*-riboside (I), isolated from red corpuscles of beef blood by Newton, *et al.* (*C. A.* **17**, 811), is also found in liver. Liver at pH 5 is allowed to autolyze for 4 hrs., coagulated by rapidly heating to 85° and filtered; the filtrate is concd. to 0.1 its vol. under reduced pressure at 50°, cooled, satd. with $(NH_4)_2SO_4$ and the resulting ppt. discarded; on standing for several days crude I seps., which is again purified from H_2O; the aq. soln. at pH 5 is then pptd. with $Hg(OAc)_2$ and the filtrate treated with AcONa (to make a 10% soln.); Hg is removed from the ppt. and the soln. concd. at 50° until crystn. begins. I seps. as needles or squares or rectangular plates, $[\alpha]_D^{20}$ −40.8° (0.1 *N* NaOH, *c* 1.25) for the I from blood or −40.6° (*c* 1.13) for the I from liver. The ultraviolet absorption spectra of I in H_2O, acid and alkali very closely resemble those of 9-methyluric acid and are quite unlike those of 1-, 3- and 7-methyluric acids in the same solvents, thus establishing the position of the ribose group. The sugar occupies the same position as in other purine nucleosides.

C. J. West



Synthesis of substances related to the sterols. XXVII. The synthesis of x-norestrone. Robert Robinson and H. N. Rydon. *J. Chem. Soc.* **1939**, 1394–405; cf. *C. A.* **33**, 7746[8].—Details are given of the prepn. of 6,2-$MeOC_{10}H_6$-Ac (I) in 120-g. yield from 192 g. 2-$C_{10}H_7OMe$. The *oxime* (II) of I m. 169–70°. Rearrangement of II with PCl_5 in Et_2O gives *6-acetamido-2-methoxynaphthalene*, m. 162–3°. Hydrolysis with HCl, transformation of the NH_2 group into the HO group and methylation with Me_2SO_4 give 2,6-$C_{10}H_6(OMe)_2$, thus establishing the structure of I. 3-(6′-Methoxy-β-naphthyl)-Δ^2-cyclopentenone-2-acetic acid and AcOH, refluxed 30 min., give 74% of 4-acetoxy-7-methoxy-3′-keto-1,2-cyclopentenophenanthrene (*C. A.* **33**, 1744[7]) (III), m. 241–2° (sufficiently pure for preparative purposes); the 4-HO deriv. (IV) gives an *oxime*, m. 268°; hydrolysis of III and methylation without isolation of IV give the 4,7-di-MeO deriv. (V). IV and V were not suitable for hydrogenation but 6.4 g. III in AcOH, reduced with Adams catalyst at 70° for 26 hrs. (4 moles H_2) and the product crystd. from AcOH and then AcOEt, gives 0.2 g. *4,3′-dihydroxy-7-methoxy-1,2-cyclopentenophenanthrene* (VI), m. 139–40°; in another expt. the product was triturated with petr. ether and crystd. from MeOH, giving the *4-Ac deriv.* of VI, m. 145°. In a 3rd expt. the product was hydrolyzed with KOH in MeOH-H_2O (5 hrs.) and distd., giving 2 fractions, $b_{0.2}$ 175–95° and $b_{0.3}$ 200–20°. The latter fraction was pptd. with digitonin, giving *4-hydroxy-7-methoxy-1,2,3,4-tetrahydro-1,2-cyclopentenophenanthrene*, m. 141–2° (*p-nitrobenzoate*, m. 214–16°); it is very resistant to oxidation. The 1st fraction on redistn. and dehydrogenation gives a mixt. of 80% of 1,2-cyclopentenophenanthrene and a MeO deriv., the latter being sepd. as the 1,3,5-$C_6H_3(NO_2)_3$ complex and the former as the picrate. These results may be regarded as exptl. evidence for preferential deoxygenation at the 4-position in the hydrogenation of 4,7-dihydroxyphenanthrene derivs. This work also indicated that in order to obtain the desired 3′-keto complex it would be necessary to open the 5-membered ring before proceeding with the hydrogenation. V (2.9 g.) and iso-$AmNO_2$ with *tert*-BuOK give 3 g. of the *2′-isonitroso deriv.*, m. 248–9° (decompn.); concd. H_2SO_4 gives a brilliant indigo-blue color; it was intended to convert this into an acid but the work was discontinued in light of the shorter route given below. V in C_5H_5N, treated successively with HCO_2Et and EtONa, gives 97% (crude yield) of the *2′-formyl deriv.* (VII), pale yellow, decomps. 195°; it gives a deep olive-green color with EtOH-$FeCl_3$; attempted condensation of V with HCO_2Et or iso-AmO_2CH in C_6H_6, Et_2O or dioxane with Na or in Et_2O with EtONa were fruitless; iso-AmO_2CH and *tert*-BuOK in a N atm. give a *condensation product*, $C_{39}H_{30}O_6$, orange, m. 301–2°; concd. H_2SO_4 gives a purple color; AcOH contg. a little HCl gives a plum color with a bright-red fluorescence. VII and NH_2OH.HCl in AcOH give a cyano ketone which is hydrolyzed by KOH in dil. EtOH (3 days on steam bath) to *4,7-dimethoxyphenanthrene-1-β-propionic-2-carboxylic acid* (VIIA), m. 285° (decompn.); *di-Me ester* (VIII), m. 115°. Reduction of VIII in AcOH with the Adams catalyst (10% by wt.) at 70° is complete in 12–48 hrs., according to the activity of the catalyst. Hydrolysis with KOH in dil.

MeOH and fractionation from C_6H_6 and then from dil. AcOH gives 3 acids: *4,7-dimethoxy-9,10-dihydrophenanthrene-1-β-propionic-2-carboxylic acid* (**IX**), m. 208–9° (10%), sparingly sol. in C_6H_6; *4,7-dimethoxy-1,2,3,4-tetrahydrophenanthrene-1-β-propionic-2-carboxylic acid* (**X**), m. 138–40°, which is more sol. in C_6H_6 than **IX**; *7-methoxy-1,2,3,4,9,10,11,12-octahydrophenanthrene-1-β-propionic-2-carboxylic acid* (**XI**), m. 233°, 25% yield; these structures are not definitely proven and the analogies on which they are based are given. Pyrolysis of the Pb salt of **XI** over a free flame at 0.25 mm. gives *7-methoxy-3'-keto-1,2,3,4,9,10,11,12-octahydro-1,2-cyclopentenophenanthrene* (*x-norestrone Me ether*), m. 142–3°; concd. H_2SO_4 gives a yellow color, becoming orange on warming; HI in AcOH gives *x-norestrone*, m. 222°, which gives a yellow color with H_2SO_4 unchanged on heating; *acetate*, m. 145–6°. Pyrolysis of the Pb salt of **IX** gives *4,7-dimethoxy-3'-keto-9,10-dihydro-1,2-cyclopentenophenanthrene*, concd. H_2SO_4 gives a bright-yellow color, with a brilliant-green fluorescence on warming; *2,4-dinitrophenylhydrazone*, deep red, m. 242 3°. The reaction failed with **X**, probably owing to partial elimination of MeOH during the pyrolysis. **IV** and Et_2SO_4 with NaOH in EtOH give 100% of the *4-EtO deriv.* (**XII**), m. 191°; the formyl deriv. from 5.2 g. of **XII** yields a cyano ketone which is hydrolyzed to 3.2 g. of the *7-methoxy-4-ethoxy analog* of **VIIA**, m. 268 9°; *di-Me ester* (**XIII**), m. 118°; this is best purified by percolation through Al_2O_3. Reduction of **XIII** gives as the only isolatable product the *7-methoxy-4-ethoxy analog* of **X**, m. 160°; **XI** or any other deoxygenated product could not be found. 7-(β-6'-Methoxynaphthyl)-4,7-diketoheptoic acid with concd. HCl-AcOH (refluxing 3 hrs.) gives 84% of *7-(β-6'-hydroxynaphthyl)-4,7-diketoheptanoic acid*, m. 171–2°; heating with dil. KOH on the water bath for 1 hr. gives 100% of *3-(6'-hydroxy-β-naphthyl)-Δ²-cyclopentenone-2-acetic* acid, yellow, m. 221 2°, which is converted by refluxing with Ac_2O for 30 min. into 64% of *4,7-diacetoxy-3'-keto-1,2-cyclopentenophenanthrene* (**XIV**), m. 196 7°; NaOH gives the *4,7-di-HO deriv.* (**XV**), m. 338° (decompn.). Expts. on the hydrogenation of **XIV** gave no useful results. Methylation of **XV** yields *V*. γ-*m*-Methoxyphenylpropyl iodide (from the chloride and NaI in 91% yield), b_{11} 155 60°, n_D^{25} 1.5773; refluxing with Et cyclopentanone-2-carboxylate and K in C_6H_6 gives 57% of *Et 2-(γ-m-methoxyphenylpropyl)cyclopentanone-2-carboxylate*, $b_{0.5}$ 187 90°, n_D^{25} 1.5167; *semicarbazone*, with 2 moles EtOH; hydrolysis and distn. with Ac_2O yield *2-(γ-m-methoxyphenylpropyl)cyclopentanone*, $b_{0.5}$ 173 7°, n_D^{25} 1.5280; *semicarbazone*, with 1 mole EtOH, m. 180°; *2,4-dinitrophenylhydrazone*, orange, m. 103–4°. The prefix "x" is used above to indicate indeterminate stereochem. configuration. C. J. West

Steroids. II. The isolation of a new androstan-3(β)-olone and of allopregnan-3(β)-ol-20-one from the urine of pregnant mares. R. D. H. Heard and A. F. McKay. *J. Biol. Chem.* **131**, 371–9(1939); cf. *C. A.* **32**, 2537⁷.—A new satd. HO ketone, $C_{19}H_{30}O_2$, has been isolated from the neutral ext. of the urine of pregnant mares remaining after the removal of the phenolic estrogens. The compd. is an androstan-3(β)-olone, $C_{19}H_{30}O_2$, and evidence is adduced that the CO group is most probably located at C_6, C_7 or C_{12}. It m. 187–187.5°, $[\alpha]_D^{24}$ −160°; *oxime*, m. 194 5°; *benzoate*, m. 206–8°. It yields on oxidation by CrO_3 in the cold a diketone, m. 157–8°, which is not identical with androstane-3,17-dione. The presence of allopregnan-3(β)-ol-20-one was confirmed. A. P. Lothrop

A 5,16-pregnadiene-3,20-diol. Adolf Butenandt and Josef Schmidt-Thomé. *Ber.* **72B**, 1960 (1939).—From 400 mg. 5-pregnene-3,17,20-triol 3,20-diacetate (*C. A.* **33**, 5862⁸), boiled 4 hrs. in 20 cc. pyridine and 1 cc. $POCl_3$, is obtained 160 mg. of *5,16-pregnadiene-3,20-diol diacetate*, m. 121°, 150 mg. of which, boiled 0.5 hr. in 10 cc. MeOH with 0.1 g. NaOH in 1 cc. water, gives 84 mg. of the *diol* (**I**), m. 168–70°, and regenerating the diacetate with Ac_2O in pyridine at room temp. I (86 mg.) with prehydrogenated Pt oxide in AcOH takes up 2 mols. H to give 45 mg. allopregnane-3(β),20(β)-diol, m. 193° (diacetate, m. 138°), which is oxidized by CrO_3-AcOH to allopregnane-3,20-dione, m. 196°. **I** shows no androgenic activity even when applied directly, in oil, to the cock's comb in 5 × 100 γ dose. C. A. R.

The chemical constitution of cholesterol. XVI. Oxidation with peracetic acid. Francesco Pirrone and Rosilde Vannucchi. *Gazz. chim. ital.* **69**, 470–8(1939); cf. *C. A.* **34**, 444⁹.—Since Pickard and Yates (*C. A.* **3**, 2679) obtained a cholestanetriol from cholesterol (**I**) in AcOH, Minovici and Vladhutza (*C. A.* **6**, 2743) a triolcarboxylic acid from **I** in AcOH-H_2SO_4 with excess perhydrol and M. and V. (*Biochem. Z.* **38**, 46(1912)) a compd., $C_{27}H_{47}OCl$, from **I** in HCl-AcOH with perhydrol, it was of interest to ascertain the effect of dil. H_2O_2 on **I** in AcOH. The oxidation was carried out in AcOH: (1) at room temp. in sunlight; (2) on a boiling water bath, and (3) at the b. p. of the reaction mixt. **I** (4 g.) and 3.6% aq. H_2O_2 (200 cc.), allowed to stand for 3 months in sunlight, water (1000 cc.) added, and the ppt. purified by EtOH, yield 0.90 g. of *diacetylcholestanetriol* (**II**), lustrous, m. 164–5°, gives the same colors in the Rosenheim, Salkowski and Liebermann-Burchard reactions as does **I**, gives a red-yellow color in concd. H_2SO_4, is insol. in aq. alkalies and acids, gives no color in hot EtOH with iodized starch, does not decolorize 10% Br in AcOH or 0.01 *N* $KMnO_4$, cannot be acetylated, and does not give an oxime. In hot alc. KOH, **II** forms the free *cholestanetriol*, $C_{27}H_{48}O_3$ (**III**), lustrous, m. 217–18°; when cold it gives no color in the Rosenheim test but when hot it gives a violet-red color, which turns red, with strong green fluorescence. In the Salkowski test, an orange-yellow color, with green fluorescence, appears slowly. In the Liebermann test an immediate violet-brown color appears, but changes to grass-green, then to brown. A $CHCl_3$ soln. of **III** does not turn the plane of polarized light. It is insol. in aq. alkalies and in dil. mineral acids; it gives no color in hot EtOH with iodized starch; it does not decolorize 0.01 *N* $KMnO_4$ nor a 10% soln. of Br in AcOH. **III** and Ac_2O, refluxed for 2 hrs. and poured into water, yield **II**. **III** and Ac_2O contg. H_2SO_4, refluxed for 1 hr. and poured into water, yield a *compd.*, $C_{31}H_{50}O_4$, m. 124–5°. The reactions indicate that perhaps 2 O atoms are present as secondary alc. OH groups and therefore that a hydroxycholestanediol is involved. To establish the character of the 3rd O atom, the work of Dunn, *et al.* (*C. A.* **29**, 807⁴) on cholestenetriol was repeated; by boiling with Ac_2O and concd. H_2SO_4 the product is a diacetylcholestenediol, m. 123 6°, obtained by Dunn (*loc. cit.*) and Westphalen (*C. A.* **9**, 2535). Accordingly the formation of **II** from **I** by AcO_2H (**IV**) in light involves simultaneous oxidation and esterification, probably as follows:

When 50 cc. 3.6% H_2O_2 is added during 3 hrs. to 3.86 g. **I** in 100 cc. glacial AcOH on a boiling water bath, the mixt. heated 3 hrs. longer, and the cold soln. filtered, there is obtained a small residue of a *compd.*, m. 63–5°; the filtrate, neutralized with NH_4OH and dild., ppts. a *compd.* $C_{24}H_{40}O_4$ (**IV**), m. 121–2°. Neither was identified. **IV** is insol. in dil. acids and alkalies, does not color hot alc. iodized starch, does not decolorize 0.01 *N* $KMnO_4$ nor 10% Br in AcOH; when cold, the Rosenheim test gives no color, but when hot an intense color with green fluorescence. The Salkowski test gives a red-yellow with green

fluorescence. The Liebermann reaction is first violet, then grass-green and finally brown. It is possible that oxidation of I takes place first at the secondary alc. groups, with formation of a ketone, and then on the lateral chain; in this case IV might be a ketonetriol. I (4 g.), 100 cc. glacial AcOH and 50 cc. 3.6% H_2O_2, refluxed for 3 hrs., filtered hot, and cooled, ppt. 300 mg. of a substance which, purified many times by EtOH-AcOH, gives III. The mother liquor from the sepn. of III, neutralized with NH_4OH and dild., yields IV. The expts. leave no doubt that under the conditions employed, oxidation of I gives a triol having 2 secondary and 1 tertiary alc. groups. The difference between the m. p. of III and that of the cholestanetriol prepd. by Mauthner and Suida (*Monatsh.* **19**, 579(1896)), Pickard (*C. A.* **3**, 2679), Westphalen (*loc. cit.*) and Windhaus (*C. A.* **1**, 1001) is not surprising, since theoretically various stereoisomers of 3,5,6-trihydroxycholesterol can exist. C.C. Davis

Experimental correlation of the plant cardiac poisons with the estrone group. Adolf Butenandt and Thomas F. Gallagher. *Ber.* **72B**, 1866–9(1939).—The widely distributed strophanthidin (I) has an aldehyde group in the place of the angular 10-Me group characteristic of most of the steroids and therefore seemed a promising material for the exptl. correlation of a cardiac poison with the follicle hormones of the estrone group, which are partially aromatized derivs. of steroids which no longer have a substituent on C atom 10. From I there has been obtained a monounsatd. ketocarboxylic acid, $C_{19}H_{26}O_5$ (II), considered to be *3-oxo-4-estrene-17-carboxylic acid*. Its prepn. is described in the present paper. I in acetone at 0–5° is oxidized with powd. $KMnO_4$ to strophanthidinic acid, m. 276°, which, allowed to stand 1 hr. at 25° in 10 vols. of 4% aq. NaOH, then dild. with water to 100 vols. and oxidized with 5% $KMnO_4$ soln., gives the ketolactonecarboxylic acid, $C_{21}H_{28}O_7$ (III), m. 260° (Elderfield, *C. A.* **30**, 4173[6]); free *trans*-ketodicarboxylic acid, from III boiled with 2% NaOH, m. 178°. III oxidized with H_2O_2 according to Elderfield gives the trihydroxydicarboxylic acid, $C_{20}H_{30}O_7$ (IV), m. 285° (di-Me ester, m. 203°). When 1.28 g. IV was dissolved in 120 cc. of 0.1 *N* alc. HCl, concd. under atm. pressure to about 10 cc., dild. with a little water and gently warmed under a current of N to incipient crystn., there was obtained 59% of the $\Delta^{14,15}$-unsatd. *anhydrodicarboxylic acid*, $C_{20}H_{28}O_6$ (V), leaflets from dil. MeOH, sinters 250°, becoming brown, and decomps. 260° (the m. p. depends on the rate of heating), $[\alpha]_D^{25}$ 122° (abs. alc.); *di-Me ester*, m. 150°, obtained from V and CH_2N_2 or by dehydration of the di-Me ester of IV. In alc. or AcOH with the Adams-Shriner Pt oxide catalyst, V is hydrogenated to the satd. *acid*, decomps. 255–6°, $[\alpha]_D^{16}$ 35° (abs. alc.) (*di-Me ester*, m. 104–5° (foaming)). 230 mg. of which, treated in 10 cc. AcOH with 66 mg. CrO_3 in 6 cc. AcOH and allowed to stand 15 hrs. at 4°, gives in varying yields (av., 32 mg.) the *hydroxyketocarboxylic acid*, $C_{21}H_{28}O_6$, m. 193–4° (foaming). This acid (68 mg.) refluxed 12 min. in 3 cc. MeOH and 0.1 cc. of 0.1 *N* alc. HCl gives II, m. 186°, sublimes without decompn., even in the presence of Cu bronze, at 110–30° under 0.001 mm., $[\alpha]_D^{25}$ 83° (abs. alc.), absorption max. 240 mμ (ε 17,200 in alc.). It shows no estrogenic activity in the castrated mouse in 4 × 750 γ doses. C. A. R.

Biochemical dehydrogenations in the cr
L.
Te
pure bacterial strain which dehydrogenates secondary steroid alcs. to the corresponding ketones. All the properties of this strain correspond to those described in the literature for *Corynebacterium helvolum* (Lehmann and Neumann) but as no culture of the latter was available

helvolum. As a member of the cortin group to be tested for its behavior toward the bacterium they selected 21-acetoxy-5-pregnen-3-ol-20-one (I), a by-product in the synthesis of desoxycorticosterone (II) (Steiger and Reichstein, *C. A.* **32**, 581[3]). I undergoes the expected dehydrogenation of the secondary alc. grouping on C atom 3, with shifting of the double bond to position 4, but at the same time the 21-AcO group is sapond. and there is obtained after shaking 6 days under O at 36–7° 34% free II, m. 139–40°; 25% of the I is recovered unchanged. The alc. group formed by sapon. of the 21-AcO group is apparently not attacked by the pure bacterium; this is confirmed by the fact that Serini and Logemann's 4-pregnene-17,20,21-triol-3-one (*C. A.* **32**, 7475[8]) remains unchanged under the same conditions. C. A. R.

Preparation of substituted cyclopentanones. Hans A. Weidlich and Margot Meyer-Delius. *Ber.* **72B**, 1941–9 (1939); cf. *C. A.* **33**, 8576[8].—Equilenin, having a naphthalene ring system in the 1st two rings of the sterol skeleton and only 2 asym. C atoms between the 3rd and 4th rings, is the simplest natural steroid and hence numerous attempts to effect its total synthesis have been made. The authors have undertaken to synthesize it by the following series of reactions, the first 5 of which they describe in this paper: Conversion of Me nerolyl ketone, 6,2-MeO-$C_{10}H_6Ac$ (I), into *5-bromo-6-methoxy-2-bromoacetylnaphthalene* (II), condensation of II with $EtCOCHNaCO_2Et$ to the diketo ester, $Br(MeO)C_{10}H_5COCH_2CH(CO_2Et)$-COEt (III), treatment of III with hot alkali to give *1-methyl-2-(5-bromo-6-methoxy-2-naphthyl)cyclopenten-5-one* (IV), and hydrogenation, with simultaneous debromination, of IV to the stereoisomeric *1-methyl-2-(6-methoxy-2-naphthyl)-5-cyclopentanones* (V). The further steps in the proposed synthesis are bromination of V to 5,6,2-Br-(MeO)$C_{10}H_5CH.CMeBr.CO.CH_2.CH_2$, condensation of this with $CHNa(CO_2Et)_2$, sapon. and decarboxylation of the product, cyclization of the resulting monocarboxylic acid to the diketone and partial hydrogenation, debromination and hydrolysis of the latter to equilenin or its stereoisomers. I (20 g.) in 500 cc. CCl_4 in ice-salt treated in the course of 1 hr., with thorough stirring, with 40 g. Br (somewhat more than 2 mols.) in 50 cc. CCl_4 gave quantitatively an orange addn. product which, on decompn. with 20 g. $NaHCO_3$, filtration from the inorg. salts, evapn. of the $CHCl_3$ and crystn. from $CHCl_3$-petr. ether, yielded II, m. 132–5° (*pyridinium compd.*, Br-(MeO)$C_{10}H_5COCH_2N(C_5H_5)Br$, faintly yellowish, decomps. 243°). Attempts to prep. $MeOC_{10}H_6COCH_2Br$ by using only 1 mol. Br resulted in the formation of mixts. from which the desired product could not be obtained. Treatment with 2 mols. Br also at first gave only mixts. In the different runs were isolated the following products, which give an insight into the course of the bromination. The 1st product was *5-bromo-6-methoxy-2-acetylnaphthalene*, m. 126–7°, mol. wt. in camphor 287; further bromination gave II and the isomeric *5,7-di-Br deriv.* of I, m. 143–6° (which was unchanged by pyridine in alc. or by long heating in pyridine alone); and finally there was obtained *5-bromo-6-methoxy-2-dibromoacetylnaphthalene*, pale greenish, m. 164–5°, which was unchanged by pyridine in boiling alc. but on long heating in pyridine gave the methylene-bis (pyridinium bromide), m. 255–8°. *Et α-propionyl-β-(5-bromo-6-methoxy-2-naphthoyl)propionate* (III), m. 100–1°; in 1 expt. was obtained a product which, when crystd. from $CHCl_3$-petr. ether, m. 187–8° and had the compn. of *Et α-propionyl-β,β'-bis(5-bromo-6-methoxy-2-naphthoyl)-isobutyrate*, mol. wt. in camphor 696. In working up III there was always obtained a very small amt. of a *compd.* $C_{36}H_{39}O_9Br_3$ or $C_{45}H_{37}O_9Br_3$, insol. in ether and acetone, m. 208–10°, mol. wt. in camphor 1051. IV, from 10 g. III in 1 l. of 2% aq. NaOH in a long-necked flask heated 2 hrs. on the water bath and finally 1 hr. to boiling over a free flame, yellowish, m. 175–7°; in 1 case was isolated a small amt. of the *carbinol*, Br(MeO)$C_{10}H_5C(OH).CH_2.CH_2.CO.CHMe$, m. 150–1°. When the cyclization product still contains unchanged III, it forms on distn. the *Et furancarboxylate*, $Br(MeO)C_{10}H_5C:CH.C(CO_2Et):CEt.O$, m. 108–10° (*free acid*, m. 249°). On hydrogenation of 2

g. IV in 200 cc. alc. with PdO-$CaCO_3$ and 0.5 g. KOH 1 mol. H was taken up in a few min. with formation of *1-methyl-2-(6-methoxy-2-naphthyl)cyclopenten-5-one* (VI), m. 113–16°; the *semicarbazone*, m. 269° (decompn.), became intensely yellow in the light and was so difficultly sol. that it could not be recrystd. When more than 1 mol. H was taken up, there was formed, in addn. to VI, the *trans-form* of V, m. 81–3°; *semicarbazone*, m. 236–7° (decompn.). With PdO in 200 cc. alc. and 70 cc. AcOEt, 2 g. IV, after absorbing 2 mols. H, gave about $^2/_3$ *cis*-V, m. 119–21° (*semicarbazone*, m. 239–40° (decompn.)), and $^1/_3$ of the corresponding *cyclopentane* (VII), m. 70° (*picrate*, red, m. 89°). VI (2 g.) in 100 cc. alc. with PdO took up 1 mol. H in 1.5 hrs. and yielded about equal parts of *cis*- and *trans*-V; in the presence of 0.2 g. KOH the hydrogenation stopped after 5 hrs. with absorption of 1 mol. H and quant. formation of *trans*-V, which, on Clemmensen reduction, gave *trans*-VII, m. 52–4° (*picrate*, red, m. 112°). C. A. R.

Study of break-down products of lignin (Bobrov, Kolotova) **23**. Hardening of phenol-CH_2O resins (Hanus, *et al.*) **13**. Dipole moment of the aminobenzoic acids in dioxane (Van Blaricom, Gilbert) **2**. Lignin (Richtzenhain, v. Hofe) **23**. Electrolysis of mixts. of pivalic acid salts with nitrates (Fichter, Gunst) **4**. Nitrates and chlorinated org. compds. (U. S. pat. 2,174,574) **18**.

Fractionating mixtures of gaseous hydrocarbons such as propane mixtures. Paul D. Barton (to Sun Oil Co.). U. S. 2,175,590, Oct. 10. An arrangement of app. is described, and a process for sepg. normally gaseous hydrocarbon mixts. which comprises subjecting the mixt. to reflux fractionation, subjecting the sepd. overhead gaseous light fractional product of the fractionation to cooling and partial condensation under a substantial super-atm. pressure, sepg. the condensate from the uncondensed gas, releasing the pressure on such uncondensed gas further to cool it, utilizing such cooled uncondensed gas as a cooling medium in the specified cooling and partial condensing step, and utilizing the sepd. condensate as reflux in the fractionation operation.

Olefins from saturated hydrocarbons. Hans Klein, Ferdinand Haubach and Wilhelm Hofeditz (to I. G. Farbenind. A.-G.). U. S. 2,174,288, Sept. 26. App. is described, and a process for the production of olefins from gaseous satd. hydrocarbons other than CH_4 which involves preheating the hydrocarbons, such as C_2H_6 or C_3H_8, to about 700° and supplying O to them while diluting it at once so as to prevent formation of strata and streaks of gas when it meets the preheated hydrocarbons, thereby producing a reaction temp. above 700° but below about 1000°, the temp. at which substantial amounts of acetylene are formed under the conditions obtaining while avoiding the formation of a flame or local overheating. Cf. *C. A.* **33**, 2903[5].

Esterification of olefins. Wilbur A. Lazier (to E. I. du Pont de Nemours & Co.). U. S. 2,174,985, Oct. 3. For producing an ester such as EtOAc, an olefin such as C_2H_4 and a satd. aliphatic monocarboxylic acid such as HOAc in the vapor phase are brought into contact with a heteropoly acid catalyst such as phosphotungstic acid on silica gel at a temp. of 150–350° and under a pressure of 10–500 atm.

Alkyl and aralkyl cyanoacetic esters. Arthur C. Cope, Walter H. Hartung and Frank S. Crossley (to Sharp & Dohme, Inc. (1929)). U. S. 2,176,018, Oct. 10. In producing isopropyl cyanoacetate or other monoalkyl or aralkyl cyanoacetic ester, isopropylidene cyanoacetic ester or other alkylidene or aralkylidene cyanoacetic ester is subjected to the action of H in the presence of an active catalyst such as Pt or Pd.

Purification of ethers. Norman D. Scott (to E. I. du Pont de Nemours & Co.). U. S. 2,174,293, Sept. 26. A nuclear addn. compd. of a polycyclic aromatic compd. and an alkali metal such as one of naphthalene and Na is used as a purification agent for ethers such as diethyl ether.

Hydroxyalkylamine ethers. Ernst M. Schwarz. Friedrich O. Zschimmer, Gotthold E. Zschimmer, Georg M. W. Schwarz and Friedrich W. R. Schwarz (trading as Zschimmer & Schwarz Chemische Fabrik Dolau). Brit. 508,525, July 3, 1939. The etherification of hydroxyalkylamines is effected in 2 or more stages, each stage comprising treatment with alkali metal and then with alkyl halide in less than the theoretical quantities required. In examples, (1) Na is added in small portions to triethanolamine (I) at 105° under reflux, the product is cooled to 75° and BuCl is added with heating to 105°, then more Na is added, followed by BuCl as before, and (2) the cetyl ether of I is prepd. similarly.

Alkyl derivatives of isobutane. Vladimir N. Ipatieff and Herman Pines (to Universal Oil Products Co.). U. S. 2,174,883, Oct. 3. Isobutane is alkylated with C_2H_4 at an alkylating temp. below 40° and in the presence of $AlCl_3$ and HCl, maintaining present during the reaction a mol. excess of isobutane over C_2H_4 and activating the reaction by the presence of a relatively small amt. of an olefin of greater reactivity than C_2H_4, such as C_4H_8.

$\Delta^{4,5}$-Unsaturated steroid ketones. Soc. pour l'ind. chim. à Bâle. Brit. 508,452, June 30, 1939. These are prepd. by subjecting to thermal decompn. a condensation product of an org. base with a steroid 2-halo-3-ketone contg. no halogen in rings A and B other than that in 2-position. In examples, (1) monobromocholestanone and pyridine are refluxed to give a cryst. condensation product, which decomp. when heated to about 300° in a vacuum; the distillate is extd. with H_2O and from the insol. portion $\Delta^{4,5}$-3-cholestenone is formed, and (2) bromoandrostan 3,17-dione is converted into its pyridine addn. compd. as in (1) and this is then decompd. under reduced pressure to give $\Delta^{4,5}$-androstene-3,17-dione.

Aliphatic-araliphatic amines. Theodor H. Temmler (trading as Temmler-Werke Vereinigte Chemische Fabriken Hermann Temmler). Brit. 508,756, July 5, 1939. Amines are prepd. by reducing aliphatic-araliphatic ketones with activated Al and H_2O in the presence of NH_3 or a primary or secondary amine. The reaction may be effected in an atm. of H under pressure. Examples are given in which (1) phenylacetone (I) and NH_2Me yield β-phenyl-*N*-methylisopropylamine, (2) I and allylamine yield β-phenyl-*N*-allylisopropylamine, and (3) I and benzylamine yield β-phenyl-*N*-benzylisopropylamine.

Hexahydro-*p*-phenylenediamine. Caryl Sly (to E. I. du Pont de Nemours & Co.). U. S. 2,175,003, Oct. 3. *p*-Phenylenediamine is catalytically hydrogenated in the liquid phase, at a temp. of 120–200° and under a pressure of 5–300 atm. in the presence of a Ni or Co catalyst.

Ketenes. Donald J. Loder (to E. I. du Pont de Nemours & Co.). U. S. 2,175,811, Oct. 10. A process for the prepn. of a ketene such as methyl ketene involves thermally decompg., in the vapor phase, a lower alkyl ester of a lower aliphatic monocarboxylic acid such as methyl propionate at a temp. between about 500° and about 1000° (suitably with use of silica gel as a catalyst.).

Production and recovery of organic oxy compounds such as amyl acetate. Theodore Evans (to Shell Development Co.). U. S. 2,175,080, Oct. 3. An arrangement of app. is described, and a process for the production of an oxy compd. such as AmOAc as by the reaction of C_5H_{10} with HOAc in which the reacted mixt. comprises a substantially water-immiscible phase and an aq. inorg. acid phase with a water-sol. org. oxy compd. distributed between the 2 phases, involving the method of removing the water-sol. org. oxy compd. from the water-immiscible phase by sepg. the 2 phases and extg. the water-sol. org. oxy-compd. from the water-immiscible phase by intimately bringing this phase into contact with a minor part of the sepd. aq. catalyst phase at a temp. substantially below that at which the initial phase sepn. was effected.

Hydrogenation of nitroparaffins. Kenneth Johnson (to Purdue Research Foundation). U. S. 2,174,498, Sept. 26. In a catalytic process for the direct hydrogenation of satd. nonbenzenoid nitrohydrocarbons such as nitrobutane or nitropropane for producing the corresponding amines, H and the liquid nitrohydrocarbon are brought

into contact with a catalyst such as a Ni catalyst at a temp. below 165° (suitably 15–150° under pressure).

Hydrogenating unsaturated materials such as rosin, abietyl alcohol, and methyl abietate. Rollin J. Byrkit, Jr. (to Hercules Powder Co.). U. S. 2,174,651, Oct. 3. An arrangement of app. is described, and a method for the continuous hydrogenation of an unsatd. material which contains the hydrocarbon nucleus of a rosin acid, that includes continuously flowing the unsatd. material in contact with H successively through a plurality of stationary hydrogenation catalyst beds while under superatm. pressure in excess of about 100 lb. per sq. in. and at a temp. within the range of about 70° to about 300° until the activity of the catalyst in the beds has dropped materially, replacing the first of the catalyst beds with a fresh catalyst bed and continuously flowing the unsatd. material in contact with H through the plurality of catalyst beds in such order that the fresh catalyst bed is the last through which the unsatd. material flows. Cf. *C. A.* **33**, 5414[1].

Catalytic dehydration of compounds such as diacetone alcohol for the production of mesityl oxide. Sumner H. McAllister and Edwin F. Bullard (to Shell Development Co.). U. S. 2,174,830, Oct. 3. A distn. process for the catalytic dehydration of a carbinol-contg. carbonylic compd to an unsatd. carbonylic compd., which forms an azeotrope with water, which contains a higher ratio of water to unsatd. carbonylic compd. than the stoichiometric ratio, involves distg. a reaction mixt. contg. a preponderance of the carbinol-contg. carbonylic compd. in the presence of a dehydrating catalyst, passing the distillate into a column and adding sufficient water to the distillate in the column to make the compn. of the top product substantially correspond with that of the azeotrope.

Reducing nitroaryl compounds. Harold G. Bowlus and Walter V. Wirth (to E. I. du Pont de Nemours & Co.). U. S. 2,175,244, Oct. 10. In effecting reactions such as the production of hydrazobenzene from $PhNO_2$, the reaction mass, formed with use of comminuted Fe and aq. alkali, is subjected to continuous attrition in a ball mill during the reaction.

Compounds of the cyclopentanopolyhydrophenanthrene series. Schering A.-G. Brit. 508,576, June 29, 1939; Fr. 838,704, Mar. 14, 1939. Such compds. contg. an aromatic ring A are prepd. from compds. of the said series in which ring A is not aromatic but which contain 1 or more double bonds in ring A and a keto or an alc. OH group or a functional deriv. of the OH group in 3-position, or derivs. thereof that contain on the C atoms 1, 2, 4 and (or) 5 a group capable of being split off with the formation of a double bond, by a thermal and (or) a mineral-acid treatment. The treatment effects the removal of the 10-methyl group or its displacement to a C atom not at a point of junction of the rings and then follows the aromatization of ring A. The starting materials may be (1) 3-ketones of steroids doubly satd. in ring A, or their enol derivs., (2) 3-ketones of steroids singly unsatd. in ring A, or their enol derivs., that in addn. possess in ring A a group capable of being split off with formation of a further double bond, (3) 3-ketones of steroids singly unsatd. in ring A between C atoms 1 and 2, and their enol derivs., (4) 3-hydroxy compds. of steroids doubly unsatd. in ring A and their derivs., (5) 3-hydroxy compds. of steroids singly unsatd. in ring A, or their derivs., that in addn. possess in ring A a group capable of being split off with formation of a further double bond, (6) 2,3- or 3,4-diketones of steroids or their enol derivs., (7) satd. 3-ketones of steroids that possess on the 2-C atom a group capable of being split off with the formation of a double bond. The term enol derivs. denotes enol esters or ethers. Instead of the free ketones, their reaction products with the customary ketone reagents, e. g., semicarbazide, phenylhydrazine, may be used. Among examples, (1) the isovalerate of hydroxycholesten-3-one obtained according to Brit. 500,353 (*C. A.* **33**, 5872[9]) is heated in a stream of CO_2 for 1 hr. at 330–340°, the product is taken up with Et_2O, washed with alkali and distd. under reduced pressure to give a light oil that is an aromatic product, (2) the 4-benzoate of $\Delta^{1,3}$-cholesten-3-one-4-ol is heated in a stream of CO_2 to 310–320° and worked up as in example (1) to give an aromatic product, and (3) 2-bromocholestan-3-one is treated with BzOK in toluene-BuOH soln., the benzoate of 2-hydroxycholestan-3-one thus obtained is purified by crystn. and sapond. and the free hydroxy compd. thus obtained is treated according to Brit. 486,596 (*C. A.* **33**, 8706[3]) by heating with agents that split off H_2O, e. g., H_3PO_4, P_2O_5, $KHSO_4$, $ZnCl_2$, to give an unsatd. compd. by the splitting off of the secondary OH group; this material is rendered aromatic and the product worked up as described in example (2).

Alkyl halides. Ober C. Slotterbeck and Raphael Rosen (to Standard Oil Development Co.). U. S. 2,174,278, Sept. 26. For producing an alkyl halide such as EtCl, an olefin such as C_2H_4 and a H halide such as HCl are passed over a catalyst contg. a halide of a metal of the 5th group, such as Bi chloride while maintaining between 2.5% and 20% of moisture in the feed gases.

Alkanesulfonyl chlorides. Cortes F. Reed (to Charles L. Horn). U. S. 2,174,492, Sept. 26. For the production of a product such as ethanesulfonyl chloride, a normally gaseous alkane such as C_2H_6 is treated with a gaseous mixt. of SO_2 and Cl. Several examples are given.

Sulfonyl halides. Treat B. Johnson (to Röhm & Haas Co.). U. S. 2,174,856, Oct. 3. A sulfonyl halide such as methane sulfonyl chloride is produced by subjecting an org. thiocyanate in which the nucleus of a C compd. is linked through a C atom to the S of the thiocyanate radical, such as methyl thiocyanate, to the action of a halogen such as Cl in the presence of water (suitably at a temp. of 5° or lower). Numerous examples are given.

Alkyl phosphites. Thomas H. Rogers, Clarence M. Loane and Bernard H. Shoemaker (to Standard Oil Co. of Ind.). U. S. 2,175,509, Oct. 10. An arrangement of app. is described, and a method of prepg. alkyl phosphites involving mixing a satd. aliphatic alc. such as BuOH with a tertiary amine such as dimethylaniline, adding a liquefied volatile hydrocarbon solvent such as butane to the mixt. and effecting reaction with PCl_3 at a temp. not higher than 10°.

Carbon sulfoselenide. Winfield Scott (to Wingfoot Corp.). U. S. 2,175,816, Oct. 10. Reaction is effected between H_2Se and phenyl isothiocyanate or other aryl isothiocyanate or aryl thiourea (suitably at room temp.) and the C sulfoselenide is recovered (suitably by distn.).

Stabilizing organic nitriles. Ralph A. Jacobson (to E. I. du Pont de Nemours & Co.). U. S. 2,175,805, Oct. 10. Distn. of glycolonitrile is effected from an aq. medium at a pH of less than 7 (suitably contg. H_3PO_4 to give a pH of less than 6).

Unsaturated nitriles. Donald J. Loder (to E. I. du Pont de Nemours & Co.). U. S. 2,175,810, Oct. 10. A process for the prepn. of unsatd. derivs. of isobutyronitrile such as methacrylonitrile involves dehydrohalogenating an α-halogenated isobutyronitrile such as α-chloroisobutyronitrile with use of $FeCl_3$ as a catalyst (suitably with refluxing)

Unsaturated aliphatic or cycloaliphatic carboxylic acid nitriles. Kurt Pieroh (to I. G. Farbenind. A.-G.). U. S. 2,174,756, Oct. 3. A process for the production of a nitrile such as methacrylonitrile comprises heating a halogen-contg. satd. aliphatic carboxylic acid nitrile such as isobutyronitrile at a temp. above 250° (suitably 400–550°) in the presence of a substance such as TiO_2 which is capable of splitting off H halide.

Concentrating aqueous solutions of acetic acid. Charles J. L. Coutor (to Établissements Lambiotte frères). U. S. 2,175,879, Oct. 10. An arrangement of app. is described, and a process which involves distg. one portion of the acid soln. azeotropically with an entraining liquid such as BuOAc to dehydrate the soln., subjecting another portion of the acid soln. to an extn. treatment in the liquid phase with a solvent for HOAc such as EtOAc to remove the acid from the soln., and evapg. the extn. solvent from the extd. acid at least partially by the heat evolved in the condensation of the vapor of the azeotropic distn., the

extn. solvent used having a b. p. low enough that it can be vaporized by such heat and also forming an azeotropic mixt. with water.

Maleic anhydride. Harold B. Foster and Joyce H. Crowell (to National Aniline & Chemical Co., Inc.). Brit. 508,489, June 30, 1939. Solid maleic acid, or a soln. thereof (preferably of 25-75% concn.), is brought into contact with a surface heated to about 160-400° so as to vaporize the acid quickly and produce a vapor of about 150° or more. The pressure may be 100-250 mm. or an inert gas may be used to assist rapid evapn. The reaction vapors may be treated with an inert org. liquid to absorb the anhydride or may be cooled fractionally to sep. first a small quantity of fumaric acid and then the maleic anhydride, H_2O being left in the vapor state.

1,1,3-Trichloroethane. Gerald H. Coleman and Garnett V. Moore (to Dow Chemical Co.). U. S. 2,174,737, Oct. 3. A method of prepg. 1,1,2-trichloroethane comprises simultaneously passing ethylene chloride and gaseous Cl, in the ratio of between about 0.2 and about 1.0 mol of Cl per mol of ethylene chloride, into a liquid reaction bath contg. above 50% of ethylene chloride, and 1,1,2-trichloroethane, while maintaining the bath at a temp. above 50°, in the presence of actinic light.

2-Ethylcrotonaldehyde. Henry L. Cox (to Carbide & Carbon Chemicals Corp.). U. S. 2,175,556, Oct. 10. A process for making 2-ethylcrotonaldehyde for subsequent hydrogenation to 2-ethylbutyraldehyde involves condensing a mixt. of butyraldehyde and acetaldehyde in molar proportions, resp., of at least 1:2 in the presence of a weak alk. soln., and dehydrating the aldol mixt. so formed by gradual addn. to a boiling soln. of not higher than 5% H_2SO_4.

Furfurylamines. Homer Adkins and Charles F. Winans. U. S. 2,175,585, Oct. 10. A process for prepg. furfuryl secondary and tertiary amines such as *N*-furfurylbutylamine involves hydrogenating under superatm. pressure, at a superatm. temp. not above about 110°, in the liquid phase and in the presence of a base metal catalyst such as a Ni catalyst, a reaction product of furfural and an amine such as butylamine which contains the group RN(R')H in which at least one of the R groups is a hydrocarbon radical. *N*-Furfuryl-*N*-(*p*-hydroxyphenyl)amine, etc., may be similarly produced.

Optically active phenylisopropylamines. Theodor H. Temmler (trading as Temmler-Werke Vereinigte Chemische Fabriken Hermann Temmler). Brit. 508,757, July 5, 1939. Racemic β-phenylisopropylamine or a *N*-homolog thereof is resolved into its optical components by means of an optically active acid. In an example, the *d*-tartrate of racemic *N*-methyl-β-phenylisopropylamine is produced and extd. with hot EtOH, in which the *d*-tartrate of *d*-*N*-methylphenylisopropylamine is readily sol. while the *d*-tartrate of the *l*-amine is sparingly sol.

Tetrahydrofurans. I. G. Farbenindustrie A.-G. Brit. 508,548, July 30, 1939. These are prepd. by heating 1,4-butylene glycol or its *C*-alkyl, -aralkyl, -cycloalkyl or -aryl substitution products in the liquid state with 1 or more solid dehydration catalysts, i. e., oxides of Al, Zr or Th, sulfates of Al and Cu, K Al sulfate, K pyrosulfate, phosphates of Al, Fe, Ce and Ag having a neutral reaction, chlorides of Mg, Ca, Zn and Al, silica gel, bleaching earths, org. acids, e. g., $(COOH)_2$, *p*-toluenesulfonic acid, acid anhydrides. The products may be obtained by fractional distn. with or without previous drying. Cf. *C. A.* **33**, 9328[2,3].

α-Picoline from divinylacetylene and ammonia. Albert S. Carter (to E. I. du Pont de Nemours & Co.). U. S. 2,175,339, Oct. 10. By a process involving passing divinylacetylene vapor and NH_3 over a catalyst which may comprise freshly reduced Pb and Cd on a carrier of alumina, etc., α-picoline is obtained with a relatively small admixt. of other products. Various related reactions and details of operation are described.

Androstenedione. Walter Schoeller, Arthur Serini and Willy Logemann (to Schering A.-G.). U. S. 2,175,220, Oct. 10. A method for producing an androstenedione of the general formula $C_{19}H_{26}O_2$ involves oxidizing an androstenolone of the general formula $C_{19}H_{28}O_2$ with an agent, such as chromic acid anhydride in coned. HOAc soln., capable of converting a secondary alc. group into a keto group. Br may be used to form a dibromide as an intermediate. Various examples with details are given.

Styrene. Consortium für elektrochemische Industrie G. m. b. H. Brit. 508,666, July 4, 1939. Styrene is prepd. by heating a mixt. of C_6H_6 vapor and C_2H_4 under reduced pressure, e. g., at about 800-1000°.

Butadiene. Victor E. Wellman (to B. F. Goodrich Co.). U. S. 2,174,280, Sept. 26. A process for producing butadiene comprises catalytically dehydrating 1,3-butanediol, sepg. the dehydration products into a low boiling fraction consisting principally of butadiene and a high-boiling fraction contg. substantially all the remaining products of the dehydration, subjecting the high-boiling fraction to fractional distn. and thereby sepg. a const.-boiling mixt. of water and 1-buten-4-ol distg. at 90-92°, chiefly at 91°, at atm. pressure, admixing a quantity of the const.-b. mixt. with 1,3-butanediol and subjecting the resulting soln. to catalytic dehydration.

Butadiene. I. G. Farbenindustrie A.-G. Brit. 508,764, July 5, 1939. Butadiene (I) is prepd. by catalytic dehydrogenation of butane to butylene (II), isolation of this from the reaction mixt. and further dehydrogenation to I. Conversion of C_4H_{10} to II may be effected at 500-600° with Al_2O_3 activated by oxides of Cr, V, W or Mo so that only up to about 35% conversion is obtained. The II is washed out with solns. or suspensions of salts that absorb olefins, e. g., $AgNO_3$, $Cu(NO_3)_2$ or $HgNO_3$ solns., and is recovered by heating or evacuating. Unconverted C_4H_{10} is recycled, and the II, after further purification if necessary, is dehydrogenated in the presence or absence of catalysts, preferably only up to about 30% conversion to I, which is removed by solns. of salts of the heavy metals of groups 1 or 2, e. g., CuCl contg. NH_4Cl or alkali chloride.

11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

ARTHUR W. DOX

The darkening of pigments by ultraviolet light of long wave lengths. G. Miescher and H. Minder. *Strahlentherapie* **66**, 6-23(1939).—The 3 pigment phenomena, direct tanning of pigmented skin in living persons by ultraviolet rays of long wave lengths, darkening of pigmented portions of skin by irradiation with a quartz lamp (Lignac's phenomenon, *C. A.* **17**, 1662), and darkening of pigmented portions of skin by warming to 56° (Meirowsky's phenomenon, *Frankf. Z. Path.* **2**, 438-48(1909); *C. A.* **3**, 2313) depend upon the darkening of the pigment through uptake of O. Melanin exists in an O-poorer form, which reduces Ag, and an O-richer form, which does not. Under the exptl. conditions, and probably also in nature, the reversibility of the 2 forms is not complete, since melanin tends to be stabilized in an O-richer form. The reduction potential of the cells effects a gradual conversion of the melanin, formed through the action of the dopa oxidase, into an O-poorer form. The darkening phenomenon depends upon the conversion of the light, O-poorer form into the dark, O-richer form through O uptake. Ruth Berggren

The prevention of Röntgen-ray leucopenia. C. Carrié and O. Schnettler. *Strahlentherapie* **66**, 149-54(1939).—Large doses of vitamin C produced a leucocytosis in rabbits. The administration of vitamin C immediately before irradiation has the most favorable effect on x-ray leucopenia. Ruth Berggren

A direct oxidase present in Pyrethrum cinerariaefolium. Mario Covello. *Ann. chim. applicata* **29**, 333–9(1939).—An active oxidase consisting of the enzymic system: peroxidase + peroxide was extd. from pyrethrum by means of 30% EtOH. Its activity is greatest at pH 4.33–4.93 at 35°. It becomes inactive on heating above 75°. A. W. Contieri

The effect of sodium oleate on liver, pancreas and serum lipase. T. I. Meerzon and T. Ya. Volpyans'ka. *Med. exptl* (Ukraine) **1938**, No. 1, 37–46.—Pancreatic lipase was activated by the addn. of Na oleate, but an increase in the ratio of the latter to the lipase (above a certain optimum) inhibited the activity of the latter. Na oleate always inhibited the activity of the liver and serum lipase irrespective of the ratio between it and the enzyme, human serum lipase being somewhat less sensitive to Na oleate than rabbit serum lipase. Addn. of inactivated exts. of the liver to pancreas lipase and *vice versa* had no effect on the Na oleate-lipase interaction. S. A. Corson

Structure of protein films. E. G. Cockbain and J. H. Schulman. *Trans. Faraday Soc.* **35**, 1266–76(1939).—The force *vs.* area and surface potential *vs.* area characteristics of pure gliadin films have been studied on buffered solns. from pH 2 to 10 at temps. from 17 to 22°. It is suggested from stereochemical considerations that a sepn. of polar from nonpolar chains of a protein at an air/water interface takes place by means of a looping of the polypeptide chains. Fully extended polypeptide chains of the β-keratin type or of any such regular pattern are not possible. The interaction between gliadin films and tannic acid is strongly dependent on pH, the nature and concn. of the anions in the underlying soln. and on the surface pressure of the film. Victor R. Deitz

Two degradation products of hemocyanin. Marcel Florkin and Charles Toussaint. *Compt. rend. soc. biol.* **132**, 15–7(1939).—The supposed prosthetic group of hemocyanin as prepd. by the method of Conant, *et al.* (*C. A.* **29**, 2189[6]) gives a green color with the orcinol-in-HCl reagent used as a test for pentoses; the compd. of Schmitz (*C. A.* **25**, 1847) does not. L. E. Gilson

Phenolase activity of different vertebrate tissues and the mechanism of the formation of adrenoxine. Ghislaine Duchateau Bosson and Marcel Florkin. *Compt. rend. soc. biol.* **132**, 47–50(1939).—Expts. by the authors indicate that the supposed phenolase activity of vertebrate tissues is not due to true phenolases but to other oxidizing systems. L. E. Gilson

A polarographic study of insulin. Oscar Kanner and G. J. Reed. *Proc. Soc. Exptl. Biol. Med.* **42**, 387–91(1939).—The height of polarographic steps of an insulin soln. is a function of the concn. of –SS– or –SH groups and independent of the intrinsic physiol. activity. Polarographic analysis permits the detn. of the concn. of insulin solns., for any given brand, after proper calibration. L. E. Gilson

Cholinesterase and esters of thiamine. David Glick and Wm. Antopol. *Proc. Soc. Exptl. Biol. Med.* **42**, 396–9(1939); cf. *C. A.* **33**, 4608[6].—Thiamine chloride acetic ester (I) was a poorer inhibitor of cholinesterase than free thiamine, and the pyrophosphoric ester (II) had even less inhibitory action. The affinity of I for the enzyme was calcd. to be 5.3, and that of II, 1.7, times that of acetylcholine. I was hydrolyzed slowly by horse serum, the magnitude of the enzymic splitting being approx. equal to the OH^- scission at the same pH (7.4). L. E. Gilson

Macromolecular [protein] components of untreated and of formolized normal chick embryo tissue. D. G. Sharp, A. R. Taylor, Harold Finkelstein and J. W. Beard. *Proc. Soc. Exptl. Biol. Med.* **42**, 459–61(1939).—Preliminary. L. E. Gilson

Lysozymes. Z. V. Ermol'eva. *Uspekhi Sovremennoĭ Biol* **9**, No. 4, 68–80(1938); *Khim. Referat. Zhur.* **2**, No. 3, 61(1939).—The utilization of the bacteriol. lysozyme, contained in tissues and secretions, in industry (conservation of caviar) and in medicine is described. Data on the sensitivity of lysozyme to bases, acids, temp., adsorption tendency, inactivation by salts of the heavy metals, are presented and its fermenting properties are noted. Lysozyme is detd. as a polypeptide contg. N 15.0, O 48.65, H 6.4, P 0.25 and S 0.64%. W. R. Henn

Effect of fluorides on salivary amylase. F. J. McClure. *U. S. Pub. Health Repts.* **54**, 2165–71(1939).—NaF, KF, NH_4F and Na_2SiF_6 have no effect on the activity of salivary amylase in concns. varying from 1.7 to 8550 p. p. m. of F present in 1 to 10 dilns. of salivas which stood for 1 hr. in the cold prior to testing amylolytic property. The same fluorides, when present in the enzyme-substrate mixt. during the digestion period, in concns. varying from 0.76 to 760 p. p. m. of F in the substrate, had no final effect on enzyme activity. The salivas of school children whose drinking water contained an av. of 1.8 p. p. m. of F showed no differences in amylolytic action from a similar group of salivas obtained under similar conditions from school children whose drinking water was free from fluoride. Eighteen references. J. A. Kennedy

Emulsin. XXXIX. The hydrolysis of methyl glycosides of some synthetic sugars by sweet almond emulsin. H. Helferich, W. W. Pigman and H. S. Isbell. *Z. physiol. Chem.* **261**, 55–60(1939); cf. *C. A.* **33**, 7826[8].—The emulsin of sweet almonds does not measurably hydrolyze the α- or β-methyl glycosides of the following synthetic sugars: *d*-lyxose, *d*-gulose, *d*-α-glucoheptose and *d*-α-galaheptose. (Nomenclature according to Isbell and Pigman, [*C. A.* **31**, 3012[4]].) **XLI. The hydrolyzability of lactobionic acid by sweet almond emulsin.** *Ibid.* 189–92; cf. *C. A.* **34**, 721[9].—A standard sweet almond emulsin prepn. hydrolyzes lactose at 30 times the rate of hydrolysis of lactobionic acid. The latter is hydrolyzed somewhat more slowly than its lactone. Milton Levy

Hydrolysis of polysaccharides with phosphorylation in muscle and sarcoma. Hans v. Euler and Erwin Bauer. *Z. physiol. Chem.* **261**, 125–36(1939); cf. *C. A.* **33**, 2106[6].—The enzyme which phosphorylates starch is adsorbed from muscle exts. by alumina Cγ (I) and to a lesser extent by kaolin but not by animal charcoal (II) or Al_2O_3. Adsorption by I is most complete at pH 5 and at 8.5 and minimal at pH 7. The enzyme is elutable with phosphate buffers at pH 7. Adenylic acid, Mn^{++} and Mg^{++} are necessary for the enzyme. Amylopectin is more readily phosphorylated than amyloamylase. Amylopectin was sepd. into 2 fractions by bringing its soln. in H_2O to 44% EtOH by vol. Both the sol. and insol. fractions were then further fractionated by $Ba(OH)_2$, each yielding 2 fractions. The rates at which the fractions are phosphorylated are not related to the P contents of the fractions. Dialyzed Jensen sarcoma exts. also contain the enzyme. M. L.

Arginase action. S. Utzino and M. Kaiju. *Z. physiol. Chem.* **261**, 137–40(1939).—A series of Ac derivs. of arginine peptides was subjected to the action of an arginase prepn. from cattle liver which had been freed from acylase and peptidase. Only slight hydrolysis occurred even with addn. of Mn^{++} and even after long times. Pancreas maceration juice hydrolyzes acetyl-*l*-leucyl-*d*-arginine and diacetyl-*l*-tyrosyl-*d*-arginine. Milton Levy

Preparation and purification of "old" yellow enzyme from yeast and a new method for reversible splitting. Friedrich Weygand and Leonhard Birkofer. *Z. physiol. Chem.* **261**, 172–82(1939); cf. *C. A.* **31**, 6264[2].—To prep. "old" yellow enzyme, yeast is air dried, macerated and the ext. treated with 3/8 vol. of Me_2CO at 0°. The filtrate is carried through the following steps 5 times: (1) adsorption on $Al(OH)_3$ at pH 5.2, (2) elution with $(NH_4)_2SO_4$ soln at pH 8.2, (3) pptn. from the eluate at pH 6 by 70% satn. with $(NH_4)_2SO_4$ and (4) soln. in H_2O. The final soln. is dialyzed. The yield is 0.4 g. per kg. of yeast. The mol. wt. from flavine estn. is 68,500–74,000. Chromatographic adsorption can be used especially on frankonite. The prosthetic group and carrier can be sepd. from yellow enzyme by adsorption from acid soln. by suitable adsorbents. Examples of the process are given. M. L.

The question of the presence of methionine in insulin. Vincent du Vigneaud, Gail L. Miller and Clement J. Rodden. *J. Biol. Chem.* **131**, 631–40(1939); cf. *C. A.* **31**, 3948[1].—When digested with HI according to the Baernstein procedure, cryst. insulin was found to liberate 0.6–0.7% volatile iodide calcd. as methionine, thus con-

firming the data of Kassell and Brand (*Proc. Soc. Exptl. Biol. Med.* **35**, 444–5(1936)) with respect to the volatile iodide. The HI digests, however, gave practically neg. tests for homocysteine thiolactone, indicating that the volatile iodide did not represent methionine but originated from some other source in the insulin mol. Preliminary hydrolysis of insulin with HCl brought about a ⅔ decrease in the volatile iodide liberated by the insulin on digestion with HI. Since there is no analogy for a decompn. of methionine with HCl under such conditions, this result is interpreted as further evidence that the volatile iodide does not have its origin in methionine. Finally it was shown that only a small portion, if any, of the volatile iodide liberated is MeI. Conclusion: methionine is absent in cryst. insulin. A. F. Lothrop

The activity of maltase from wheat and rye flour. Alfred Rotsch. *Biochem. Z.* **301**, 418–28(1939).—In an aq. suspension of wheat or rye flour there is a synthesis of glucose by maltase in addn. to the diastatic hydrolysis of the starch. The flour suspensions were made very thick (3 parts flour to 5 parts H_2O) to demonstrate this synthesis. In suspensions of rye flour a considerably higher glucose concn. was found. S. Morgulis

The use of radioactive forms of the common elements in physiology. A. Barnett. *Phys. Rev.* **56**, 963(1939).—Artificially radioactive elements are used as "tracers" in physiol. expts.: conclusions are usually drawn on the assumption that the ordinary and the radioactive element behave alike. The charge on the cell membrane and the polar properties of the lipoid mols. in this membrane would be modified by the radiations. Proteins near the cell wall might be denatured, grossly modifying surface conditions. The validity of conclusions drawn from such exptl. work is questioned. G. M. Petty

Specific magnetization of methemoglobin. Paulette Berthier. *Compt. rend.* **209**, 774–6(1939); cf. *C. A.* **33**, 4607⁴.—The coeff. of sp. magnetization of methemoglobin was detd. at 10.5° in soln. with suitable addns. of HCl or NaOH. Immediately on prepn. of the soln. k_0 for pH 1.1, 3.2, 7.2, 8.2 and 14.0 was +0.46, +0.04, +0.15, −0.18 and −0.21, resp. With time k increases in acid sols, and decreases (in neg. value, ultimately becoming pos.) in alk. sols; in H_2O it remains const. But the sols show signs of gradual decompn. C. A. Silberrad

Constitution of the purine nucleosides (Falconer, Gulland) **10**. Emulsin (Helferich, *et al.*) **10**. Biochem. dehydrogenations in the cortin group (Mamoli) **10**.

Enzymic manufacture of nucleotides. Pawel Ostern (to Dr. Georg Henning, chemische pharmazeutische Werk G. m. b. H.). U. S. 2,174,475, Sept. 26. Adenosine-5-monophosphoric acid is obtained by a process which involves adjusting a phosphate buffer soln. to a pH of 6.0–7.5, introducing adenosine into the soln., adding beer yeast to the soln. and agitating the resulting mixt. at a temp. of 10–50°. Various details of procedure are described.

B—METHODS AND APPARATUS

GLENN E. CULLEN

The estimation of aneurin by thiochrome reaction with Pulfrich photometer. A. Mukherji. *J. Indian Chem. Soc.* **16**, 273–80(1939); cf. *C. A.* **31**, 1443⁶.—Jansen's method (cf. *C. A.* **33**, 3834³,⁴) for the estn. of aneurin was modified by (1) carrying out the oxidation of aneurin in the presence of CO_2, (2) estg. the thiochrome formed by comparison of the ultraviolet fluorescence (a Pulfrich photometer is used instead of a Cohen fluorometer) and (3) decreasing the quantity of isobutanol used from 13 cc. to 3–4 cc., thus increasing the fluorescence of the test soln. Results from the use of the modified method on urine, polished rice, carrot, bread and com. vitamin B complex are included. George Ayers

A standardized Wohlgemuth procedure for α-amylase activity. R. M. Sandstedt, Eric Kneen and M. J. Blish. *Cereal Chem.* **16**, 712–23(1939).—Wohlgemuth values are commonly indicative of combined activity of α- and β-amylase. Increasing the ratio of β-amylase to α-amylase in the starch-enzyme mixt. increased the rate of dextrinization up to a point beyond which further increments of β-amylase have essentially no effect. The quant. measurement of α-amylase, therefore, involves the addn. of sufficient supplementary β-amylase to eliminate the variable effect of β-amylase already present in the malt ext. The prepn. and use of an easily reproducible red-brown dextrin-I soln. as a standard end point are described. The linear relationship between α-amylase content and dextrinization time permits calcn. of α-amylase units as the no. of g. of sol. starch which, under the influence of an excess of β-amylase, are dextrinized by one g. of malt in 1 hr. at 30°. The application of the method to barley malts and the lack of parallelism between α-amylase activity and either saccharogenic or dextrinogenic activity of malts is discussed. L. H. Bailey

A modification of the Wohlgemuth method for the determination of alpha-amylase and a comparison of this method with r viscosity method. Lawrence E. Ehrnst, Geo. J. Yakish and Wm. Olson. *Cereal Chem.* **16**, 724–9 (1939).—Full details of method are given. L. H. B.

Investigations on the separation of some enzymes of emulsin by means of chromatography. Géza Tóth. *Magyar Chem. Folyóirat* **45**, 103–8(1939).—A 4% aq. soln. of emulsin (Merck) was led through a 5-cm. layer of bauxite. This layer retained 79% of β-glucosidase. The filtrate contained 3% of β-glucosidase, 70% of α-galactosidase and 90% of chitinase. A second, 3.5-cm. layer of bauxite was used for chromatography to retain 75% of α-galactosidase. The filtrate contained practically no β-glucosidase nor β-galactosidase and consisted chiefly of chitinase. The adsorbed enzymes could always be easily dissolved by dild. ammonia. The bauxite used was commercial ore finely powd. and mixed with 30% quartz sand to increase its permeability. S. S. de Finály

Determination of pregnandiolglucuronic acid in urine. Roger Crismer. *Compt. rend. soc. biol.* **132**, 50–2(1939).—An improved method of defecating the urine and extg. with BuOH is described. L. E. Gilson

A crystal form which precedes the formation of Teichmann crystals in the test for hemoglobin. M. Goulliart. *Compt. rend. soc. biol.* **132**, 108–11(1939).—The dried blood or hemoglobin is mixed on a slide with glacial AcOH or a 1% soln. of HCl in AcOH. Rusty-appearing shuttle-shaped crystals slowly form. If glacial AcOH contg. a little KI is used as the reagent all hemoglobins and chlorocruorins form, in about 30 min., dichroic boat-shaped crystals of protoiodoheme which change gradually into square tabular Teichmann crystals. The reaction is hastened by warming. L. E. Gilson

The precipitation reaction of erythrocytes in test tubes. V. A. Shangin. *Lab. Prakt.* (U. S. S. R.) **1939**, No. 7, 30.—It is recommended to replace the watch glass with short test tubes (1.5–2 cm. diam., 2–2.5 cm. long) when the velocity of the pptn. of erythrocytes is detd. Advantages are easier mixing and complete removal of the liquid. W. R. Henn

The determination of iodine in thyroid glands. F. Reimers. *Dansk Tids. Farm.* **13**, 237–51(1939) (German summary).—Hunter's method (*J. Biol. Chem.* **7**, 321 (1909)), U. S. P. XI, was modified by the addn. of 10 ml. of 30% NaOH before titration. This gave a pH of 2.2. In the acetic acid method the only change was the use of H_2SO_4, evapn. to 175 ml., neutralization by NaOH and the addn. of glacial acetic acid before titration. Citric acid, giving a pH of 2.2, was also used in place of the glacial acetic acid. When these modifications were used the results of the methods were in better agreement than with the methods given in the U. S. P. Otto Johnson

The determination of thiocyanate in serum after the administration of its salts. Emanuel Ginsburg and Norbert Benotti. *J. Biol. Chem.* **131**, 503–17(1939).—The detn. of thiocyanate is carried out directly upon serum by addn. of acid $FeCl_3$ without preliminary pptn. of protein, thus shortening and greatly simplifying the procedure. The color is read in a microphotoelec. colorimeter. Recovery from normal serum is within ±2% and from serum with a concn. of bilirubin as high as 7.4 mg. %, 96–99%

recovery is possible. The method affords a working limit of 7.5 mg. % in which range the Lambert-Beer law holds accurately. By diln. of the original serum, the upper limit may be extended to 15 mg.% with negligible error. A. P. Lothrop

A combination simple manometer and constant-volume differential manometer for studies in metabolism. Wm. H. Summerson. *J. Biol. Chem.* **131**, 579–95(1939).—The app. described is a combination manometer offering in a single app. the possibilities of either direct or differential manometric measurements. For direct measurements it is the equiv. of 2 single manometers of the conventional Barcroft-Warburg type in which one limb is open to atm. pressure. As a differential manometer it operates at const. vol. with the attendant simplification of differential measurements made possible by use of const.-vol. vessel consts. The differential readings are equally significant at high or low vessel pressures and a sensitive manometer fluid may be used since only pressure differences are allowed to influence the manometer. It is adaptable for use with a variety of vessel types and has proved equally suitable for the study of metabolism in Ringer-phosphate soln. or in those solns. which must be maintained under physiol. conditions of gas tension such as Ringer-bicarbonate soln., blood serum and other physiol. fluids. The application of the app. to the differential measurement of the O_2 consumption, respiratory CO_2 output and aerobic glycolysis of tissues is illustrated. A. P. Lothrop

Note on hemoglobin estimation. John McGrath. *Irish J. Med. Sci.* [6], No. **166**, 740–2(1939).—A short review. G. H. W. Lucas

C—MICROBIOLOGY

LAWRENCE H. JAMES

Influence of purification of brewers' yeast by the pharmacopeial method upon its biological value. Z. Markuze and St. Biniecki. *Arch. Chem. Farm.* **4**, 37–40 (in English, 40)(1939).—The effect of the purification of brewers' yeast according to the method specified in the Polish Pharm. (2nd edition) was studied with regard to the N, P and vitamin B contents of the product. It was found that the total N and P content of the purified yeast is slightly lower, and that of purine N is slightly higher than in the initial product. Lipides, glycogen and other carbohydrates are unaffected. Purified yeast contains slightly more vitamin B_1 (50 I. U. per g., as compared with 45 I. U. for the unwashed yeast); the content of vitamin B_2 is 10 and 5–10 Akroyd-Roscoe units, resp. So the pharmacopeial method of washing yeast does not involve removal of active constituents of yeast, and it even slightly raises its vitamin B content. E. A. Ackermann

Denitrification and hydrogen-ion concentration. Astrid Karlsen. *Bergens Museums Årbok* **1938**, No. 2, 38 pp.—Expts. on the influence of the H-ion concn. on denitrification in a strain of *Pseudomonas aeruginosa* (Schroet.) Migula are described. In nutrient solns., contg. KNO_3, the min. lies at about pH 5.8 to 6.0, the max. at about 9.0 to 9.2. The optimum varies with the nitrate concn. In NO_3 nutrient solns. both the min. and the optimum varies with the NO_2 concn. At all concns. the max. point lies at about 9.2 to 9.4. It is suggested that the explanation of the varying places of the optimum point in the expts. with 27.4 mg. nitrate N may be the varying NO_2 accumulation, which interferes more or less with the denitrification process in the crit. range near the point of neutrality. Fe in measurable quantities is necessary for the denitrification process. With $FeCl_3$ 0.07 to 0.1 mg. Fe per 100 ml. soln. seems to be the optimal concn.; 0.2 mg. Fe has a deleterious effect. Fe citrate furthers the denitrification process in concns. of 0.1 and 0.2 mg. Fe per 100 ml., and 0.2 mg. Fe has a greater effect than 0.1 mg. Fe citrate in a concn. of 0.2 mg. Fe per 100 ml. accelerates the nitrate decompn. both in the min. range pH 5.5 to 7.0 and in the max. range 8.6 to 9.2. The addn. of Fe, especially citrate Fe, favors particularly the NO_2 decompn., not the reduction of nitrate to NO_2. Low temps., 1.5° to 5.0° have no influence on the course of the pH curve of denitrification. The expts. described were made with growing bacteria. The denitrification, considered as a purely enzymic process, may have other cardinal pH points than those found in the expts. V. Aschehoug

Thiamine and symbiosis. Wm. J. Robbins. *Bull. Torrey Botan. Club* **66**, 569–72(1939); cf. *C. A.* **33**, 5890².—Symbiosis may occur between fungi that are heterotropic and those that are autotropic for thiamine. Thus *Penicillium* may supply thiamine to *Phycomyces*. R. C. Burrell

Preparation of antigens Vi and O [of typhoid bacillus]; their serological reactions. Ivan Malek. *Compt. rend. soc. biol.* **132**, 15–18(1939).—Discussion. **Antigenic properties of antigens Vi and O.** *Ibid.* 18–20.—The two protein-free antigens are almost identical in their antigenic properties. **Influence of the glucide-lipide antigens on cultures of Eberthella typhi.** *Ibid.* 24–5.—Addn. of either antigen to a broth culture stabilizes the organisms against flocculation by Na salts or acids. L. E. Gilson

Metabolism of the tubercle bacillus in Long's synthetic medium. Theodore E. Friedemann and Florence B. Seibert. *Proc. Soc. Exptl. Biol. Med.* **42**, 41–3(1939).—In Long's medium (*C. A.* **20**, 2535) growth was rapid and was directly related to the consumption of glycerol and other org. components of the medium. Rapid autolysis occurred after exhaustion of the nutrients. No lactic acid was formed. L. E. Gilson

Effect of chlorophyll derivatives and related compounds on the growth of Mycobacterium tuberculosis. Sylvester Daly, Geo. Heller and Erich Schneider. *Proc. Soc. Exptl. Biol. Med.* **42**, 74–8(1939).—Chlorin-e and chlorophyllin in concns. of 0.025 and 0.05% in glycerol broth and in Sauton's medium inhibited the growth of H37 and avian tubercle bacilli. In similar concns. Cu chlorin-e, deuteroporphyrin, Cu deuteroporphyrin and the Na salt of pyrroporphyrinsulfonic acid did not retard growth. The pellicles were colored by the compd. used. The absorption spectra indicate that Cu chlorin-e unites chemically with the bacillary protein to form a complex. L. E. Gilson

Toxicity of "Q" substance from Eberthella typhosa. E. W. Dennis. *Proc. Soc. Exptl. Biol. Med.* **42**, 89–92 (1939).—The "Q" substance (cf. White, *C. A.* **26**, 2238; **29**, 488⁹) prepd. from typhoid bacilli is lethal to mice and rabbits when given in sufficient doses. Its toxicity is attributed to its necrotizing action, which appears to be due to a toxic compd. formed from the "Q" substance and serum protein. L. E. Gilson

Anticatalase activity of sulfanilamide and related compounds. IV. Peroxide accumulation and growth inhibition in pneumococcus. Edna R. Main, Lawrance E. Shinn and R. R. Mellon. *Proc. Soc. Exptl. Biol. Med.* **42**, 115–18(1939); cf. *C. A.* **33**, 8231⁷, 8296⁸.—The effect of sulfanilamide, and 11 related complex compds. capable of inhibiting catalase, upon growth and accumulation of H_2O_2 in broth cultures of pneumococcus was detd. The concn. of H_2O_2 per unit of growth was 2–10 times greater in the presence of compds. which caused bacteriostasis than in control cultures. *p*-Aminobenzamide, the carboxylic acid deriv. corresponding to sulfanilamide, showed no bacteriostatic activity. *p*-Nitrobenzamide was markedly bacteriostatic. L. E. Gilson

Fluorescence and absorption spectra of a flavin isolated from a toxic culture filtrate of Corynebacterium diphtheriae. M. O'L. Crowe. *Proc. Soc. Exptl. Biol. Med.* **42**, 212–15(1939).—Preliminary report. L. E. Gilson

Bacteriostatic effect of sulfapyridine, sulfanilamide and prontosil rubrum in vitro on mycobacteria. Konrad E. Birkhaug. *Proc. Soc. Exptl. Biol. Med.* **42**, 275–7(1939). —Human, bovine and avian tubercle bacilli were used, also *Myc. johnei*, *Myc. piscium* and *Myc. paratuberculum*. Both sulfapyridine and prontosil rubrum produced significant inhibition of growth of the cultures in 10 mg.% concn. and sometimes complete inhibition in 50–90 mg.% concn. Sulfanilamide in 50 and 90 mg.% concn. was less effective than sulfapyridine in 10 mg. % concn. L. E. Gilson

Filterability of bacteria. S. P. Kramer. *Proc. Soc.*

Exptl. Biol. Med. **42**, 448–51(1939).—If one filters a 1: 30,000 soln. of night blue, a colloidal basic dye, through a siliceous filter, Berkefeld N, the filtrate is colorless. If a wetting agent (blood serum, bile, Na taurocholate, glycocolic acid, Turkey-red oil, common soap, castor-oil soap, lecithin, Na lauryl sulfate, etc.) is added to the dye soln. the dye passes through the filter. In like manner the addn. of one of the above wetting agents to the culture suspension enables *B. subtilis*, *Streptococcus hemolyticus* and typhoid and other bacilli to pass through the Berkefeld N filter. In some cases the meat broth used as a culture medium may contain enough soap or other active substance to produce the effect. L. E. Gilson

Substance "B" in lactic fermentation according to the scheme of Van Laer. Hervasio Guimarães de Carvalho. *Rev. brasil. chim.* **8**, 122–7(1939).—Discussion. L. E. Gilson

The bacteriostatic and antitoxic actions of sulfanilamide. Joseph T. King, Austin F. Henschel and Beryl S. Green. *J. Am. Med. Assoc.* **113**, 1704–9(1939).—Tissue-culture studies of the bacteriostatic properties of sulfanilamide indicate that it is effective against β-streptococci. Reduction in hemolysis accompanied bacteriostasis. The drug modifies the normal mode of division and reduces the ability of the organism to invade the clot. F. P. G.

Forssman antigen in tubercle bacilli. Cesare Perondi. *Boll. soc. ital. biol. sper.* **14**, 500–2(1939).— No Forssman antigen was found. Helen Lee Gruehl

Forssman antigen in ox organs. V. Cavina. *Boll. soc. ital. biol. sper.* **14**, 503–6(1939).—No Forssman antigen was demonstrable in ox liver, spleen, kidney, lungs, blood or brain. Helen Lee Gruehl

Action of methyl *p*-hydroxybenzoate on tubercle bacilli. M. Adorni Braccesi. *Boll. soc. ital. biol. sper.* **14**, 508–10 (1939).—Concns. of 0.05% to 0.15% proved effective in inhibiting the growth of various strains. H. L. Gruehl

Bacterial symbiosis with legumes and nonlegumes. H. Schanderl. *Gartenbauwiss.* **13**, 406–40(1939).—*B. radicicola* was detected in plants of the Papilionacea and isolated under aseptic conditions not only from root nodules but from the roots, sprouts, leaves and seeds as well. Bacteria, apparently of the same type, were also isolated under similar conditions from various organs of nonleguminous plants, including those belonging to the Compositae, Cruciferae, Graminae and Caryophyllaceae. Bean ext. media proved more successful than agar media for the isolation of the bacteria. Symbiosis between *Diplotaxis tenuifolia* and N-fixing bacteria was demonstrated in a pot expt. on kaolin sand (contg. 0.007% N) with N-free nutrient soln. This plant and several others were found growing on a kaolin sand hill from a kaolin mine. The lack of energy material in this substrate indicated the improbability of the presence of nonsymbiotic N-fixing bacteria. The evidence for the source of the symbiotic N-fixation residing solely in the root nodules is discussed. Conclusion: The evidence is more favorable for the hypothesis that N assimilation takes place in the leaf or other aerial portion of the plant. 35 references. C. K. Horner

The occurrence of Colletotrichum lindemuthianum (Sacc. & Magn.) Bri. & Cav. in broad bean seeds. T. F. Yu. *Bull. Chinese Botan. Soc.* **3**, No. 1, 1–19(1937).— In an aq. medium contg. 1% dextrose and 1% peptone and at a temp. of 28°, no growth of the fungus occurred at pH 3.1 and only slight growth at pH 4.4. Max. growth was made at pH 7.3–8.4 and some growth took place at pH 11.6. Two strains of the fungus showed practically identical behavior with respect to pH. In a soln. composed of $MgSO_4$ 0.8, KCl 1.0 and $NaNO_3$ 2.0%, the *Vicia* and *Phaseolus* strains showed little difference in the amt. of growth in the presence of a no. of carbohydrates, but in raffinose soln. the mycelial growth of the latter was 3 times that of the first. K. D. Jacob

The effect of chaulmoogra oil and related substances upon the growth of Mycobacterium avium in vitro. Robert Graham, L. E. Boley and Norman D. Levine. *Cornell Vet.* **29**, 357–9(1939).—Chaulmoogra oil in a concn. of 1:100 apparently inhibited the growth of but did not kill *M. avium*. Concns. lower than 1:500 had no effect. The Na salts of the total acids of *Hydnocarpus wightiana* in concns. of 1:100–1000 also inhibited growth but were not toxic. Na diheptyl acetate gave similar results. K. D. Jacob

The mold Byssochlamys fulva. II. T. G. Gillespy. *Univ. Bristol, Fruit Vegetable Preservation Research Sta., Campden, Ann. Rept.* 1938, 68–78; cf. *C. A.* **33**, 2605⁸.— The asci of *B. fulva* are most resistant to heat at pH 5.0 and the resistance at a given temp. and pH increases with the concn. of sucrose in the medium. All ascospores were destroyed when the medium was subjected to initial and final heatings for 10 min. each at 77° with an intermediate heating for 30 min. at 46°. A 38% survival of the ascospores occurred when the medium was heated continuously for 20 min. at 77°. K. D. Jacob

Biochemistry of Endoconidiophora fimbriata (E. et H.) Dav. I. Kenzi Miyazi. *J. Agr. Chem. Soc. Japan* **15**, 831–5(1939).—The sweet potato or the potato ext. contg. 3% of sucrose was most suitable for the culture soln. of *Endoconidiophora fimbriata*. The black pigment was produced in the soln. It showed the properties of caramelan. It may come from the sugars but not from the starch. Alc., fusel oil, aldehyde, acetone, AcOH, fumaric acid, malic acid, kojic acid and glycerol were detected as the fermentation products. Y. Kihara

Study of a new acetone-resistant stock of acetone-ethyl alcohol bacteria with special reference to the possibility of increasing the concentration of industrial mashes. M. D. Chumak. *Bull. acad. sci. U. R. S. S., Sér. biol.* 1939, 145–54.—An acetone-resistant strain of *B. acetoethylicum*, grown on sterile potato cultures, was found to be suitable for the fermentation of concd. (25–60%) potato mashes. For concns. exceeding 60% fermentation was limited only by the viscosity of the mash. For 5–10% corn mashes fermentation by *B. acetoethylicum* was very slow owing to a lack of N in suitable form. Addn. to such mashes of inorg. N ($(NH_4)_2SO_4$) or of the aq. ext. from potatoes accelerated fermentation. John Livak

Biochemical reactions of Leishmania tropica. H. A. Senekji. *Am. J. Trop. Med.* **19**, 601–4(1939).—Seven locally isolated strains of *Leishmania tropica* were uniform in biochem. reaction in that they produced no indole or liquefaction of gelatin and no acid or gas from carbohydrates. The methyl red reaction and the Voges-Prauskauer reaction were neg. They produced rapid peptonization of milk and were bile sol. G. H. W. Lucas

The effect of various substances used as energy supply of microbe growth when introduced separately in culture media. Auguste Sartory, Jacques Meyer and André Netter. *Bull. acad. méd.* **121**, 815–19(1939).—The substances studied were Bios II prepd. from egg yolk by Kögl's method (cf. *C. A.* **29**, 2563¹), vitamin B_1, thiazole, pyrimidine, nicotinic acid, inositol and heteroauxin, tested on staphylococcus. Bios represents the only true energetic factor in these expts. The other substances, as far as necessary for growth, give no further benefit once the min. requirement has been supplied. A. E. Meyer

The mechanism of the pathogenic action of anthrax bacilli. H. Peter. *Zentr. Bakt., Parasitenk.*, I Abt., Orig. **144**, 463–71(1939).—Prior treatment with monohalogen acids, especially monochloroacetic, lengthens the life of a mouse injected with anthrax. This is probably due to inhibition of proteolytic enzymes. 13 references. John T. Myers

A rapid simple and reproducible method for the determination of bacterial sugar fermentations. J. G. Davis. *Zentr. Bakt., Parasitenk.*, II Abt. **101**, 97–101(1939).—A freshly grown mass culture on agar or in a suitable liquid medium is washed with tap water, taken up with about 30 cc. of tap water, 6 cc. of phosphate buffer pH 6.8 (equal vols. of 0.1 *M* Na_2HPO_4 and 0.1 *M* KH_2PO_4), 3 cc. of 0.01% bromocresol purple and 21 cc. of tap water. Approx. 5-cc. amts. are distributed in clean but not sterile test tubes. To each tube is added 10–20 mg. of the test sugar with a sterile Pt spatula. The tubes are closed with rubber stoppers, incubated at 37° and examd. after 3, 16

and 24 hrs. A clear yellow indicates a pos. result. Controls of each constituent should be run. J. T. Myers

An experimental study of the relation between concentration of disinfectants and time required for disinfection. F. W. Tilley. *J. Bact.* **38**, 499–510(1939).—The bactericidal efficiencies of phenol, *o*-cresol, *p*-cresol, *p*-butylphenol, resorcinol, propylresorcinol, EtOH and BuOH against *Staphylococcus aureus* and *E. typhosa* were detd. by a modified Rideal-Walker technique. From the resulting data values for the concn. exponent, n, were calcd. by the formula: $n = (\log t_2 - \log t_1)/(\log C_1 - \log C_2)$. The value of n thus obtained was then substituted in the formula $n \log C + \log t = \log A$ (A const.). Values of n and $\log A$ thus derived could be employed in this same equation to calc. either time or concn. when only one of these factors was known. The values of n seem to be characteristic for each disinfectant with each organism. John T. Myers

Studies on the hemolytic streptococcus. III. Polysaccharide and protein fractions encountered in the precipitation of erythrogenic toxin from culture filtrates. Aaron H. Stock. *J. Bact.* **38**, 511–24(1939).—The following extraneous products were encountered in preliminary expts. aimed at isolation of erythrogenic toxin from streptococcic culture filtrates: a peptone polysaccharide, a uronic acid polysaccharide, a yellow "oil," sirupy protein products from medium and an acid-precipitable protein. The polysaccharide from peptone can support streptococcic growth but it is not an essential growth factor. The uronic acid polysaccharide differed from the above by giving a strong uronic acid test (naphthoresorcinol), a neg. direct Morgan and Elson test for *N*-acetylglucosamine and a pos. test for hexosamine after acid hydrolysis. The oil gave a pos. Molisch and a pos. biuret. One cc. of oil in 9 cc. of water rotated polarized light +0.05°. Toxin was isolated from the filtrates only when some of these substances were present to act as adsorbent agents during pptn. with alc. 22 references. John T. Myers

Studies with the agar cup-plate method. I. A standardized agar cup-plate technique. S. Brandt Rose and Ruth E. Miller. *J. Bact.* **38**, 525–37(1939).—The following technique is suggested for testing antiseptics by this method. Use a standard organism; if it is *Staphylococcus aureus* use the F. D. A. strain or one of equal resistance to phenol. Grow the organisms in broth for 18 to 24 hrs. and standardize the suspension to 1 billion per cc. Ext. agar, pH 6.8, may be used. If necessary for some organisms use infusion agar, pH 7.4. Always designate the medium. The final agar concn. should be 1.5%. A 3% agar can be dild. with saline, protein (serum, blood) or protein saline mixts. Seed the medium with 0.1 cc. of standard suspension per 30 cc. Place 30 cc. of seeded medium in a Petri dish. Remove a disk of agar 1.5 cm. in diam. Use 0.2 cc. of a given dilu. of the antiseptic in each cup. The plates should be ready for incubation within 1 hr. after seeding. Incubate the plates for 24 hrs. at 37° and measure the zone of inhibition. This technique yields consistent results with phenol, $HgCl_2$ and crystal violet.

III. The influence of agar on mercury antiseptics. Ruth E. Miller and S. Brandt Rose. *Ibid.* 539–47.—Metaphen, merthiolate, $HgCl_2$ and mercurochrome were tested at various dilns. in broth and agar in the presence of varying amts. of blood. The test organism was *Staph. aureus* of standard resistance (F. D. A.). Agar exerts little or no effect on the antiseptic properties of Hg compds. The effectiveness of Hg compds. varies with the dilu. of the antiseptic and the blood content of the medium according to the general formula $y = Kx^n$, where y is antiseptic dilu., x is the blood concn. at which dilu. y is bactericidal, K and n are consts. for each organism. At certain crit. blood and antiseptic levels the compds. studied have no antiseptic properties. The antiseptic potency is not directly related to the Hg content of the compd. J. T. Myers

Studies on immunizing substances in pneumococci. X. The relationship between the acetyl group and Type I pneumococcus polysaccharide antigenicity. Lloyd D. Felton and Benjamin Prescott. *J. Bact.* **38**, 579–93 (1939); cf. *C. A.* **33**, 7873[7].—A study of the effect on antigenicity for white mice of both alk. and acid treatments of the polysaccharide of Type I pneumococcus prepd. by both Heidelberger (cf. *C. A.* **30**, 8296[9]) and Ca phosphate methods yielded the following results: NH_4OH (sp. gr. 0.89) at room temp. caused little alteration in N content, glucose no., precipitin titer, immune precipitible N, or optical rotation. Acid hydrolysis reduced the distillable acid, but the distillate did not give a test for HOAc. Antigenicity remained unchanged no matter by which method the polysaccharide was prepd. Treatment at room temp. with $N/1$ NaOH produced no change in the immunizing power of either sample, but the Heidelberger sample no longer gave a pos. test for HOAc in the vacuum distillate. Acid hydrolysis at 100° with either 5% phosphoric or *p*-toluenesulfonic acid destroyed the acetyl groups present in the Heidelberger sample yet produced no change in antigenicity. Also this treatment did not change the antigenicity of the Ca phosphate sample. Hence the presence of the acetyl group has no relationship to antigenicity. 19 references. John T. Myers

Evaluation of the tubercle bacillus concentration methods of Petroff, Pottenger and chemical flocculation. A. H. Nagy. *J. Lab. Clin. Med.* **25**, 67–71(1939).—Pottenger's (*Am. Rev. Tuberc.* **24**, 583(1931)) diln.-flotation method gives an av. of 33 times as many bacilli as can be obtained in direct smears of choice particles in routine work. The efficiency of this method is twice that of chem. flocculation and 4 times that of Petroff's (*Tuberculosis, Bacteriology, Pathology, and Lab. Diagnosis* 1927) NaOH method. Howard W. Robinson

Observations on MacConkey's and desoxycholate-citrate agars for the isolation of dysentery bacilli. J. V. Irons, S. W. Bohls, Thelma DeShazo and L. L. Hewlett. *J. Lab. Clin. Med.* **25**, 81–5(1939).—Desoxycholate-citrate medium is superior to MacConkey's agar for the isolation of Flexner dysentery bacilli. The former medium should be used along with a less restrictive medium in the bacteriol. investigation of acute diarrheal disorders. Where typhoid and paratyphoid bacilli are sought a medium more suitable for the purpose should be used. Howard W. Robinson

Anaerobic degradation of cysteine by B. coli. III. Optical specificity of cysteinase. Pierre Desnuelle. *Enzymologia* **6**, 387–91(1939)(in French); cf. *C. A.* **33**, 8677[8].—Under the action of *B. coli* cells which have been adapted to synthesize cysteinase, a given amt. of *l*-cysteine gives rise to twice as much H_2S as can be obtained from the same amt. of *dl*-cystine. The amts. of H_2S obtained from *l*-, *dl*- and *meso*cystine in the presence of glucose correspond exactly to the amts. of *l*-cysteine capable of being formed during the course of reduction by the bacteria of the different optical isomers. If *dl*-cystine is submitted to the action of *B. coli* in the presence of glucose it is possible, when all the *l*-cystine has disappeared, to isolate pure *d*(+) cystine $[\alpha]_D^{25}$ 211°. Felix Saunders

Sugar assimilation by living yeast. Changes taking place in the first few minutes. A. Mirski and E. Wertheimer. *Enzymologia* **7**, 58–71(1939)(in German).—Immediately after the addn. of glucose to living yeast cells at 30° there is a decrease in the amt. of acid-sol. phosphate in the cell. After a few min. a decrease of 40–50% is observed. The phosphate decrease persists throughout the entire period of sugar breakdown. After the period of glucose utilization, the phosphate curve gradually returns to normal. Addn. of phosphate to the fermentation mixt. has no effect on the phosphate curve. Interruption of the sugar breakdown by washing out the sugar present, or addn. of iodoacetate at the lowest point of the phosphate decrease lead to an immediate increase in the acid-sol. phosphate. Fluoride prevents this increase, and even makes the phosphate decrease still greater. If the acid-sol. phosphorylated product formed during the first 15–30 sec. of fermentation is heated 3 hrs. with N HCl it is completely hydrolyzed. If the incubation period is increased beyond 15–30 sec. the acid-sol. product is not completely hydrolyzed by heating 3 hrs. The longer period of incubation also leads to the formation of an acid-insol. compd. Corresponding with the decrease in acid-sol. phosphate

there is a decrease in pH. By working at low temps. (5–8°) it can be shown that the decrease in acid-sol. phosphate precedes the breakdown of the sugar. No glycogen formation can be demonstrated. A brief cooling of resting cells decreases the amt. of acid-sol. phosphate but in the presence of KCN or an atm. of N this decrease does not take place. At const. temp. KCN or N increases the acid-sol. phosphate. Felix Saunders

Total luminescence of bacterial suspensions in relation to the reactions concerned in luminescence. Frank H. Johnson. *Enzymologia* 7, 72–81(1939)(in English).—Detns. of luminescence intensity confirm the observations that the decrease in luminescence with time, when washed cells of luminous bacteria are aerated in phosphate buffer plus glucose, results neither from an exhaustion of the glucose nor from a possible accumulation of toxic metabolites. When glucose is added to portions of a washed cell suspension after successively longer periods of aeration, the resulting increase in luminescence takes place more slowly and the max. intensity attained is less. The total luminescence over a period of some hrs., however, is approx. the same. The characteristics of the time decrease in luminescence intensity are influenced by relatively small amts. of K and Cl. With Cl and no K, luminescence intensity is highest, after glucose addn., and decreases logarithmically with time. The data are discussed in relation to the hypothesis that an irreversible luminescent oxidation of luciferin by luciferase in bacteria follows a reduction of an oxidized form of luciferin (different from that resulting from luminescent oxidation) by dehydrogenase activity. The general form of all the curves for luminescence intensity in relation to time after adding glucose may be described by differential equations on the basis of these 2 reactions. Felix Saunders

Vitamin B_1 and acetate oxidation by bacteria. J. H. Quastel and D. M. Webley. *Nature* 144, 633–4(1939).—The oxidation of AcOH by suspensions of propionic acid bacteria grown on a vitamin B_1-deficient medium is greatly accelerated by the addn. of small amts. of the vitamin. Expts. indicate that the catalytic agent is cocarboxylase (vitamin B_1 pyrophosphate) rather than vitamin B_1 itself. E. D. Walter

Conversion of starch to crystalline dextrins by the action of a new type of amylase separated from cultures of Aerobacillus macerans. E. B. Tilden and C. S. Hudson. *J. Am. Chem. Soc.* 61, 2900–2(1939).—When *Aerobacillus macerans* is grown for several weeks upon a potato medium and the culture fluid is filtered through a Berkefeld N filter to remove the microörganisms, the filtrate contains an enzyme which converts gelatinized starch to a high rotating ($[\alpha]_D$ 203°) mixt. of nonreducing dextrins, of which the cryst. α- and β-dextrins of Schardinger are components, without the production of maltose, glucose or other reducing sugars. The culture filtrate (0.5 ml.) will convert 30 mg. of starch in a total vol. of 1.5 ml. in 30 min. at 40°; at 30° the time is twice this period and at 20° 4 times; at 50°, however, the time is more than half that required at 40°, indicating that some inactivation occurs at the higher temp. The enzyme is active over a pH range of 5.6–6.4. It is pptd. by 37.5% Me_2CO in the cold and can be extd. from this ppt. with 0.1 the original vol. of H_2O. The activity of the enzyme is unimpaired in this purification. From the above results it is inferred that the α- and β-dextrins are not products of the synthetic metabolism of the organism but are either the true components of starch or are closely related to such true components.
C. J. West

The antigenic structure of hemolytic streptococci of Lancefield group A. IV. Nucleoprotein components: Some chemical and serological properties, and changes in both caused by certain enzymes. Charles A. Zittle. *J. Immunol.* 37, 1–16(1939).—The type-specific *M* substance extd. from undried whole streptococci with 0.05 *N* HCl at 56° and isolated by pptn. at pH 3.5 was characterized as a nucleoprotein on the basis of P and purine-N content and chem. behavior; the protein was deficient in tyrosine and tryptophan on the basis of neg. Millon and Hopkins-Cole reactions. The nucleic acid, on the basis of color tests and the action of ribonuclease, was of the ribose-type. Ribonuclease caused detectable chem., but not serological, changes in prepns. of *M*. *M* was serologically inactivated by trypsin in less than 5 min. after which *M* could not be pptd. with acid. Protein fragments and nucleic acid were recovered from the tryptic digest of *M*. *M* was also inactivated by Cl-H_2O which formed a ppt. in acidic solns. The nucleoprotein *NPA*, obtained after sonic disintegration of the organisms, differed from *M* in giving pos. Millon and Hopkins-Cole reactions and contained both ribose- and desoxyribose-type nucleic acids. V. **The lack of interference of blood-group A substance in culture media with chemical and serological studied on streptococcus hemolyticus.** Werner Henle and Gertrude Henle. *Ibid.* 149–57.—Serological tests show that the presence of blood-group *A* substance in culture media contributed by the peptone usually does not interfere with the chem. fractionation of organisms from such media. The small amts. present with the organisms can be removed by careful washing 3 times. An interference in serological work seems to be excluded also. Charles A. Zittle

The isolation and properties of the specific polysaccharide of type B Hemophilus influenzae. John H. Dingle and Leroy D. Fothergill. *J. Immunol.* 37, 53–63(1939).—A simplified, peptone-free, liquid medium was used for the growth of *H. influenzae*. After the removal of the organisms the medium was concd. to 0.1 vol., pptd. with 1.5 vol. of EtOH. The ppt. was purified by repeated soln., in the presence of Na acetate made acid to litmus with glacial AcOH, and pptn. with EtOH and subsequent treatment with chloroform and BuOH. The yield from 10 l. of culture media was 0.228 g. The product was characterized by pos. Molisch test, pos. naphthoresorcinol test for glucuronic acid, neg. biuret test. Analytical data: N 0.3, C 30.7, H 5.4, ash 27.4, P 8.54 and reducing sugar (as glucose) 27%. Less than 1% of the total P was in the form of inorg. phosphate; after 5 hrs.' hydrolysis 92% was detd. as inorg. phosphate. Specific pptn. occurred in a diln. of 1:35,000,000 with immune horse serums and 1:12,000,000 with immune rabbit serums. Pptn. with various rabbit serums was specific but certain horse serums exhibited cross reactions which immunologically did not appear to be due to contamination. C. A. Z.

The disintegration of bacteria by mechanical means. I. Description and capabilities of a new type of ball mill. Paul H. Langner, Jr., and James S. Forrester. *J. Immunol.* 37, 133–6(1939).—A ball mill is described which in grinding dry hemolytic streptococci at low temp. (CO_2 ice) in 2 hrs. rendered 40% of the total bacterial N sol., in 3 hrs. 55%. Similar results were obtained with other organisms. Grinding at room temp. compared favorably with grinding at low temp. Also grinding a packed, wet mass of whole organism at room temp. was successful. II. **Comparative efficiency of the low temperature ball mill and the sonic oscillator.** *Ibid.* 136–40.—A comparison is made of the new type of ball mill with the sonic oscillator (Chambers and Flosdorf, *C. A.* 30, 6408[7]) and another type of ball mill (Mudd, *et al.*, *C. A.* 31, 6271[8]).
Charles A. Zittle

A new Schick toxin. E. M. Taylor and P. J. Moloney. *J. Immunol.* 37, 223–32(1939).—A historical review of the development of the Schick test is presented dealing chiefly with efforts to stabilize and standardize the toxin. On the basis of their work the authors conclude it is advantageous to have Schick toxin of higher toxicity than the present standard of the League of Nations and it is preferable to use for its prepn. "fresh" rather than "matured" toxin. A comparison of such a Schick toxin with the present standard is given; out of 205 tests 178 interpretable readings were obtained for the former, 166 for the latter. The conditions for maintaining the stability of the new toxin are described. 18 references. Charles A. Zittle

Pneumococcal capsular polysaccharide in urine; detection by precipitation and centrifugation. Paul F. De Gara, Samuel C. Bukantz and Jesse G. M. Bullowa. *J. Immunol.* 37, 305–20(1939).—**The minimal amt. of spe-**

cific polysaccharide detectable after its addn. to normal urine and the optimal amt. of rabbit antibody required for detection was investigated for various types of pneumococci. The minimal concn. detectable for types 1, 3, 4 and 14 was 1:200,000 and for 2, 5, 7 and 8, 1:400,000. Pooled rabbit serums were successfully used to facilitate the testing. Concn. of urine contg. polysaccharide yielded roughly equal increases in the concn. of polysaccharide found. Centrifugation at 2000 r. p. m. for 30 min., immediately after mixing of urine and antiserum, gave reactions more evident than the usual procedure of incubation at 37° for 2 hrs. and refrigeration overnight. The reaction has been used to identify the infecting type of pneumococcus in patients whose sputums yielded several types. Charles A. Zittle

The effect of temperature upon combination and aggregation and upon equilibrium in the reaction between antigen and antibody. Edna M. Follensby and Sanford B. Hooker. *J. Immunol.* 37, 367–82(1939).—A decrease in temp. from 40° to 5° has little influence upon the speed of combination between diphtheria toxin and antitoxin, but has a marked influence upon the flocculation time; the equil. attained in optimal mixts. of diphtheric toxin and antitoxin was independent of temp. Diphtheric toxin and antitoxin will combine in the presence of an amt. of salt insufficient for flocculation. Pptd. antiovalbumin will combine with ovalbumin, and temp. has little if any effect upon the equil. attained in the mixt. Charles A. Zittle

Chemical and immunological studies of the pneumococcus. V. The soluble specific substances of types 1–32. Rachel Brown. *J. Immunol.* 37, 445–55(1939); cf. *C. A.* 27, 3748; 31, 7923[9].—By the use of ultrafiltration and repeated fractional alc. pptns. in the cold in the presence of Na acetate, highly purified prepns. of the type-specific substances were obtained from broth-culture filtrates of pneumococci of types 1 through 32. The method appears to be simpler and possibly less drastic than those previously used; comparative data are given for types 1, 2, 3, 4, 8 and 14. Data in tabular form, for the 32 types, are given for Kjeldahl N, amino N, P, Ac group, ash, specific rotation, relative viscosity and precipitin titer. In some cases data are given for different prepns. of the same strain and type and also for different strains of the same type. Ten types probably represent N-free carbohydrates; 5 others (types 1, 4, 5, 12 and 25) contained a max. of 4–5% of N; the remainder contained $^1/_4$–$^3/_4$ of this amt. The type-1 substance contained 2% amino N; the others contained none or very small amts. (the detn. was made only if the total N was above 3%). The P content of 9 of the types was less than 0.5%; in 13 it was 3% or higher; type 32 contained 6.38%. Evidence is given that this is neither inorg. phosphate nor due to contaminating "C" substance. The percentage of acetyl ranged from 0.32 for type 3 to 16.33 for type 11; the high values cannot be due to the presence of Na acetate as there is no correlation between the amt. of ash and of acetyl groups. All of the prepns. showed optical activity except type 23; 2 prepns. of this type showed $[\alpha]_D$ of −0.8 and −0.4°. Type 1 was the most active with $[\alpha]_D$ of +253.2 and +255.6° for 2 prepns. Twenty-five of the prepns. were *d*-rotatory; 7 were *l*-rotatory. The relative viscosities of 0.1% solns., in 0.9% NaCl at 20°, ranged from 1.06 for type 5 to 2.79 for type 3. Qual. chem. tests of 1% solns. gave neg. biuret and ninhydrin, neg. I test for glycogen; picric and trichloroacetic acid tests were neg. The Molisch test was pos. in all cases. Before hydrolysis only types 5, 21 and 32 reduced Fehling soln.; after hydrolysis reduction was marked in every case. The naphthoresorcinol test for uronic acids was pos. in 9 cases (types 1, 2, 3, 8, 9, 12, 22, 25, and 27). The dimethylaminobenzaldehyde test for amino sugars was neg. before hydrolysis; after acid hydrolysis the test was strongly pos. in 17 types, weakly so in 3. The pptg. action of 11 acids and salts, with 1% solns. of the type substances, were investigated; of these $(NH_4)_2SO_4$ and basic lead acetate gave the most general pptn. All of the prepns. pptd. homologous immune serums in dilns. as high as 1:4,000,000 or 1:8,000,000.
Charles A. Zittle

THOMAS G. PHILLIPS

Chemical composition of diploid and tetraploid Lolium perenne L. J. T. Sullivan and W. M. Myers. *J. Am. Soc. Agron.* 31, 869–71(1939).—Percentages of dry matter, total alc.-sol. matter, crude fiber, sugars, insol. N, alc.-sol. N and total N in diploid and tetraploid plants of *Lolium perenne* are tabulated. The tetraploid plants are higher than the diploid in reducing sugars, sucrose, total sugars and in the proportion of dry matter that is sol. in 80% alc. J. R. Adams

Studies in tropical fruits. VI. A preliminary consideration of the solubility of gases in relation to respiration. E. R. Leonard. *Ann. Botany* [N. S.], 3, 825–43(1939); cf. *C. A.* 33, 4289[9].—The vols. of the gases chiefly involved in respiration, and dissolving in H_2O at the partial pressures, total pressures and temps. most frequently encountered under biol. conditions, are given in the form of tables and graphs. Data are also given of the soly. of other gases in H_2O, of N_2, O_2 and CO_2 in solvents other than H_2O and of the effect of solutes on the soly. of these gases. Tables and graphs are provided showing the percentage of the total vol. of gas in soln. occupied by each constituent gas and the vols. of these gases liberated from such solns. with rise in temp. An example is given of the application of these tables based on values of gas concns. observed in respiration studies of the papaw. **VII. Notes on banana fruits in relation to studies in metabolism.** C. W. Wardlaw, E. R. Leonard and H. R. Barnell. *Ibid.* 845–60.—For the Gros Michel banana data are given of wts. of individual "fingers" and of the proportion of pulp to skin during development up to the final senescence and collapse of the individual plant. R. C. Burrell

Further studies on transport in the cotton plant. VII. Simultaneous changes in the production and distribution of dry matter under varying potassium supply. E. Phillis and T. G. Mason. *Ann. Botany* [N. S.], 3, 889–99 (1939); cf. *C. A.* 31, 732[4].—It was found that dry wt. and its distribution (rest of plant: leaf lamina) are highly correlated under varying K supply. This correlation holds both under conditions of low as well as high K supply. No such correlation was observed for N, while the results for P were inconclusive. It is suggested that K controls the rate of photosynthesis by altering the rate at which CO_2 diffuses to the chloroplasts and that it controls equally the rate of sugar export from the chloroplast to the phloem of the leaf by altering the rate at which sugar diffuses through the protoplasm of the parenchyma. R. C. B.

Excretion of nitrogenous substances from root nodules: observations on various leguminous plants. G. Bond and J. Boyes. *Ann. Botany* [N. S.], 3, 901–14(1939).—Consistently neg. results were obtained from sand culture expts., confirming that excretion is not a const. factor of the healthy growth of leguminous plants. These results are at variance with those of Virtanen (*C. A.* 32, 5140[2]). It is just possible that differences in illumination (Glasgow and Helsinki) might have been responsible for the different results. R. C. Burrell

Light, transpiration, salt absorption and leaf structure. A contribution to the problem of sun and shade leaves. R. Bötticher and L. Behling. *Flora* 34, 1–44(1939).—The most important and characteristic part of the structure of sun leaves is conditioned by an increased salt intake which is controlled by the transpiration and the light. K seems to be more firmly bound in strongly lighted plants than in controls kept in the dark. The latter may lose K to the medium through their roots and absorb it again when placed in light, even when the transpiration rate is unchanged. R. C. Burrell

Effect of type and period of storage on cottonseed after treatment with organic mercury dusts. L. E. Miles. *Phytopathology* 29, 986–91(1939).—There was a beneficial effect not only on control of seed-borne diseases but also on germination. Seed could be safely treated any time between harvest and subsequent planting date. Under the conditions of the test the types of storage had no significant effect on results. R. C. Burrell

Role of auxin in the growth and growth movements of the higher plants. P. Boysen-Jensen. *Scientia* **66**, 233–40 (1939).—General discussion. L. E. Gilson

The influence of size on the dry matter, mineral and nitrogen content of hyacinth bulbs. J. Hargrave and F. C. Thompson. *J. Pomology Hort. Sci.* **17**, 185–94(1939). —Dry matter, sol. ash, K_2O, P_2O_5, CaO and N contents were compared on 6 different sizes of hyacinth bulbs, namely, 6, 8, 10, 12, 14 and 16 cm. in circumference. The 6-, 8- and 10-cm. sizes were all significantly higher in dry matter than the larger bulbs. The K_2O, P_2O_5 and N contents decreased between 6 and 8 cm. (not significant for N) and then increased with increasing size to a max. in the 16-cm. bulbs. This increase of all 3 constituents may be connected with the increased capacity of the bulb for flower formation, root development and foliage production. CaO content decreased with increasing size up to 10 cm. and suddenly rose in the 12-cm. size with a decline thereafter. Sol. ash content reflected the rise and fall in the P_2O_5 and K_2O contents. The size of bulbs seemed to have a definite influence on the chem. compn. Thirteen references. John O. Hardesty

Seasonal variations of starch content in the genus Rosa, and their relation to propagation by stem cuttings. Dorothy Brandon. *J. Pomology Hort. Sci.* **17**, 233–53 (1939).—A series of expts. was carried out to ascertain the rooting capacities of various species and varieties of the genus *Rosa*, with variations in the time of insertion and in treatment prior to insertion. Hardwood cuttings were taken at intervals throughout the winter. The highest rooting percentage was obtained during the period Oct.–Dec. With softwood cuttings inserted in the summer, June was the best time for rooting. After prepn., the cuttings were subjected to various chem. treatments. Ethylene chlorohydrin, thiourea, $NaNO_3$, glucose and β-indoleacetic acid were used in suitable concns. β-indoleacetic acid (1:10,000 to 1:50,000) and glucose (1%) increased the rooting percentage while ethylene chlorohydrin and thiourea depressed it slightly. No treatment gave pronounced increase or acceleration in rooting. pH of the solns. had very little effect on the subsequent rooting. Different species and varieties of the genus *Rosa* may be divided into groups comprising those in which the starch remains throughout the winter, and those in which it disappears. Botanically related species and varieties fall in the same groups, indicating that starch variation is a genetically related phenomenon among species of the genus *Rosa*. Starch accumulation in the spring was delayed by pruning. Starch content of the cuttings had no relation to facility of rooting. Eighteen references.

John O. Hardesty

Biochemistry of lucerne (Medicago sativa L). R. B. Gelchinskaya. *Biokhim. Kul'turnykh Rastenii* **2**, 236–59(1938); *Khim. Referat. Zhur.* **2**, No. 2, 59(1939).—A monograph devoted to the chem. compn. of lucerne and to the influence of external conditions on its growth and its properties. The biochem. utilization of lucerne and the dynamics of substances in the process of the development of the plant are given special attention. W. R. H.

The biochemistry of the cacao bean; present state of knowledge. H. F. Birch and E. C. Humphries. *Ann. Rept. Cacao Research* **8**, 40–2(1938)(Pub. 1939).—A review, with 37 references. K. D. Jacob

The effect of sex- and posterior pituitary hormones on plant growth. Tadahumi Mabuti. *J. Oriental Med.* **31**, 211–28(German abstr. 21)(1939).—Ova hormone 500–2000 international units) accelerates the growth of the seedling of "hakusai" (a sort of cabbage), but when heated shows no action. Praehormone (anterior pituitary prepn. 300–600 rat units) inhibits the growth, while the heated prepn. does not. Neogeburtin (posterior pituitary prepn. 30–60 international units) accelerates the growth, and when heated still retains this power. S. T.

"Gormands" (abnormal suckers) in the sugar cane. F. Martin. *Bull. assoc. chim.* **56**, 619–24(1939).—Certain cane varieties, especially P. O. J. 2878, have a tendency to produce abnormal suckers during dry weather in fertile soils; these are low in sucrose and salts, and high in reducing sugars. Their formation can be avoided by irrigation during the dry season. F. W. Zerban

Vegetable growing in nutrient salt solutions. Alexis Michailoff. *Bull. assoc. chim.* **56**, 625–30(1939).—The significance of this new method is discussed. It may be applicable to the growing of sugar beets. Bibliography of 43 titles. F. W. Zerban

Yellow pigment of *Papaver nudicaule* (Price, *et al.*) **10**. Report of the agricultural chemist [on seasonal fluctuations of HCN in several varieties of Queensland plants] (Gurney) **15**.

New information on the relation between liver function and vitamin B_1. Yosiho Hirata. *Oriental J. Diseases Infants* **23**, 23–31(1938)(in German).—Vitamin B_1 produced a marked increase in the liver glycogen of healthy rabbits. In rabbits with liver dysfunction caused by injections of $CHCl_3$ the administration of vitamin B_1 completely removed the pronounced decrease in liver glycogen as well as the pathol. disturbance, revealed by the sugar-tolerance test, and produced a distinct improvement in the degeneration of the liver. Vitamin B_1 restores liver function, especially the detoxicating action of the liver.

Ruth Berggren

Biological activity of synthetic *dl*-α-tocopherol (vitamin E) on male rats. Preliminary note. H. W. Julius and Chr. Engel. *Acta Brevia Neerland. Physiol., Pharmacol., Microbiol.* **9**, 196(1939).—Doses of 2–8 mg. of synthetic *dl*-α-tocopherol and of wheat-germ oil were not able to restore the fertility of male rats in a curative test. Tocopherol and wheat-germ oil + 5–40 units of gestyl or pregnyl or both were also ineffective. In the prophylactic test on male rats tocopherol and wheat-germ oil were equally effective. E. Curzon

Interdependence of vitamin B_1 and manganese. II. Manganese, copper and iron metabolism in B_1-deficient rats. Marta Sandberg, David Perla and Olive M. Holly. *Proc. Soc. Exptl. Biol. Med.* **42**, 368–71(1939); cf. *C. A.* **33**, 8712[3].—The depletion period of rats on a vitamin B_1-deficient diet was shortened 7–10 days if the rats received 1 mg. Mn daily. The rise in blood pyruvic acid from the initial value of 3.74 mg. % to a peak of 7.28 occurred a week earlier in rats receiving Mn than in rats on a Mn-free diet, both groups being deprived of vitamin B_1. Rats deprived of B_1 stored more Mn than those given B_1. Changes in Cu and Mn metabolism in the absence of vitamin B_1 were not significant. **III. Manganese, copper and iron metabolism in normal rats.** David Perla, Marta Sandberg and Olive M. Holly. *Ibid.* 371–4.—When rats were given a normal diet supplying about 100 γ Mn daily they stored no Mn. When the Mn intake was increased some Mn was stored, and the amt. stored was markedly increased when an addnl. 400 γ vitamin B_1 was given daily. Some dietary Cu was retained at all times, the amt. decreasing when the Mn was increased but increasing again when Mn and B_1 were given together. Vitamin B_1 did not influence Cu metabolism when the Mn intake was only 100 γ per day. Changes in Fe metabolism were not significant. L. E. Gilson

Effect of a high-fat diet on carbon dioxide-combining power of blood plasma. Helen L. Wikoff and Joseph F. Vincent. *Proc. Soc. Exptl. Biol. Med.* **42**, 382–6(1939).—A high-fat diet had no characteristic effect on the CO_2-combining power of human blood plasma. When on identical diets the CO_2-combining power of the plasma was slightly greater in men than in women. L. E. Gilson

Factors in the recurrence of renal calculi. Charles C. Higgins. *J. Am. Med. Assoc.* **113**, 1460–5(1939).—Review with clinical observations. Proper control of the pH of the urine by diet is important in preventing recurrent formation of calculi. F. P. Griffiths

Riboflavin requirements of ducklings. James C. Fritz, Wallace Archer and Donald Barker. *Poultry Sci.* **18**, 449–54(1939).—The riboflavin requirement for optimum growth of White Pekin ducklings, at least during the 1st

few weeks, is about the same as that for chicks and is not less than 800 γ per 100 g. feed. Results obtained with purified diets indicated that ducklings require a factor or factors not needed by chicks. A leg deformity that occurred when the birds were raised on semipurified diets contg. more than 60 p. p. m. of Mn, the lack of which is responsible for perosis in chicks, seemed to be of nutritional origin. K. D. Jacob

The effect of different cereals on the composition of the edible portions of cockerels. H. M. Harshaw. *Poultry Sci.* **18**, 486–91(1939).—Corn-fed birds were the highest in the fat content of the edible portions, followed in order by those reared on wheat, control, barley and oat diets. The percentage of protein, ash and water in the edible portions of the birds reared on the 5 diets varied inversely with the fat content, but the edible portions of the wheat-fed birds were consistently lower in protein than were the same portions of the birds of the other groups. The cereals used showed no tendency to cause any difference in the distribution of fat between the edible portions. K. D. Jacob

The photographing of the line test in vitamin D determinations. P. Fønss Bech. *Dansk Tids. Farm.* **13**, 253–7(1939).—An improved technique for obtaining photographs of the line is described. Otto Johnson

Studies on some possible causative factors of the spontaneous adenomatous lesion of the stomach in mice of strain I. H. B. Andervont. *U. S. Pub. Health Repts.* **54**, 2085–93(1939).—The stomach lesion is not communicable and is not, apparently, caused by an infectious agent. The lesion is not the result of *vitamin A* deficiency. It is suggested that the phys. state of the diet may exert some influence upon the development of the lesion. It is also suggested that mice may be of some use in the study of vitamins. Six references. J. A. Kennedy

Riboflavin deficiency in man (ariboflavinosis). W. H. Sebrell and R. E. Butler. *U. S. Pub. Health Repts.* **54**, 2121–31(1939); cf. *C. A.* **33**, 2187⁶.—Lesions on the lips and seborrheic accumulations on the face similar in appearance to the condition formerly described as pellagra occurred in women on a diet low in riboflavin and were alleviated and prevented by the administration of synthetic riboflavin but were not benefited by nicotinic acid. These lesions are a manifestation of riboflavin deficiency. Sixteen references. J. A. Kennedy

Growth of young rats and the formation of vital-staining erythrocytes. Hans v. Euler and Maj Malmberg. *Z. physiol. Chem.* **261**, 103–9(1939).—The reticulocyte count falls in rats on diets deficient in vitamin A. It is restored to normal when the deficiency is repaired. Similar relations hold when the diet is deficient in the whole vitamin B complex. Nicotinic acid amide in such rats does not restore the reticulocytes but dried brewers' yeast does. Milton Levy

Filtrate growth factor, B_w. Hans Kringstad and Gulbrand Lunde. *Z. physiol. Chem.* **261**, 110–24(1939); cf. *C. A.* **32**, 7084⁶.—Cane sugar is a better constituent for basal diets in the study of the vitamin B complex than is starch which contains some of the factors. For a B_6-free diet the protein source should be casein which has been purified by soln. and repptn. several times. Fish proteins contain B_6 and can be used to study the other factors. Fuller's earth adsorptions are not suitable for complete sepn. of the B factors in yeast, B_6 always remaining in the filtrate at pH 5–6. At pH 1, other B factors are adsorbed. At strongly acid reactions, substances can be adsorbed which are toxic to the avitaminotic rats. Phosphotungstic acid quantitatively ppts. B_6. Mercuric acetate ppts. neither B_6 nor B_w (filtrate factor necessary for rat growth). Factor B_w is not extd. by ether from acid soln. It is therefore not identical with the chick antidermatitis factor (Jukes, *C. A.* **33**, 3849⁵). Estns. of the amt. of B_w in various marine products are given based on a rat unit which is the amt. necessary to bring about a wt. increase of 7 g. per week during 4 weeks when added to a diet contg. 18% fish meal, 68% sucrose, 8% peanut oil, 2% cod liver oil, 4% salt mixt., 10 mg. vitamin B_1 and 20 mg. vitamin B_2 per 100 g. Milton Levy

The protective action of vitamin C on visceral lesions produced by chronic intoxication with phenylquinoline-carboxylic acid. Pietro Tagariello. *Sperimentale* **93**, 429–54(1939).—Daily injections of 200 mg. vitamin C for 3 days effected in the dog a certain degree of protection against parenchymal lesions by cinchophen. The formation of gastric ulcers was not prevented. A. E. Meyer

Studies in experimental dehydration. Dorothy W. Asher and Horace L. Hodes. *Am. J. Med. Tech.* **5**, 216–34(1939).—Albino rats at weaning were put on either a basal or a high-protein diet for 3 weeks, and then dehydrated by either diminishing the water intake or by withdrawing water entirely. In both treatments, those animals on the basal diet survived longer than those on the high-protein diet. When water was withdrawn completely, the serum proteins showed a definite rise. Rats were killed at various intervals on diminishing water intake, and their bodies analyzed for water, fat, ash, N, Cl, Na, K and P. The percentage of these elements in the whole body remained the same in the exptl. animals as in the controls. These results indicate that loss of body water is accompanied by a parallel loss of salts and N when dehydration is complicated by starvation. D. A. M.

Vitamins in theory and practice. Howard B. Lewis. *Ann. Internal Med.* **13**, 749–54(1939).—A review. John T. Myers

Occurrence of vitamin B_2 (lactoflavin). IV. The absorption of lactoflavin by proteins. Josef Schormüller. *Z. Untersuch. Lebensm.* **78**, 124–38(1939); cf. *C. A.* **33**, 7356⁸.—In the preceding report of this series, it was revealed that proteins absorb vitamin B_2. This has now been confirmed with horse and goose muscle. It appears also that in addn. to an absorption a solution process plays a role. The processes are reversible because the flavin can be eluted from the flavin-satd. muscle fibers. Considerable amts. of flavin appear in the ppt. when proteins are flocculated with tungstates, zinc sulfate or trichloroacetic acid. The importance of this unspecific binding phenomenon to transport and exchange of lactoflavin in organisms, to vitamin B_2 content of foods and vitamin-free diets, to reliability of biol. action of proteins and to analytical investigations for flavin are discussed. M. M. Piskur

Effect of vitamin C and related substances upon glycogen metabolism. Kiyosi Terada. *Tohoku J. Exptl. Med.* **36**, 180–210(1939).—*l*-Ascorbic acid, *d*-araboascorbic acid, and plant materials such as lemons, mandarins, apples, green tea, strawberries, tomatoes, watermelon, acted directly to increase the glycogen production in the liver of rabbits. Most of the plants contained substances (flavones) which further stimulated ascorbic acid to produce glycogen. This is considered an indirect effect and is named factor II. Some plants such as bitter oranges and green tea exerted a neg. action on factor II. The pos. action of plants does not depend on their vitamin C content alone. This was demonstrated by expts. in which 1 cc. of lemon juice (which contains only about 5 mg. vitamin C) added to sugar infusions produced more liver glycogen than was produced by 50 mg. *l*-ascorbic acid. T. gives the name vitamin C_2 to this glycogenic substance which is regarded as including 2 factors, one acting directly, the other indirectly on the glycogen depot of the liver. Twenty-six references. Maurice M. Rath

Application of the quantitative indicator method to the determination of the time of passage of food through the intestinal canal. Lauri Paloheimo, Milka Pirilä, A. Koskinen and T. Puokka. *Biedermanns Zentr. B. Tierernähr.* **11**, 370–88(1939).—Cr_2O_3 was used as an indicator to det. the distribution of food in the intestinal canal of rats and cattle at definite periods after eating. Felix Saunders

The importance of vitamin B_6 and factor W in the nutrition of dogs. J. M. McKibbin, R. J. Madden, Simon Black and C. A. Elvehjem. *Am. J. Physiol.* **128**, 102–10 (1939); cf. *C. A.* **33**, 981⁶.—Dogs may be raised successfully on a highly purified or synthetic vitamin B complex free ration when properly supplemented. In addn. to thiamin, riboflavin and nicotinic acid the dog also requires

vitamin B_6 and a filtrate factor which may be identical with factor W. Preliminary evidence indicates that the chick antidermatitis factor may also be needed by the dog. E. D. Walter

Antisterility factors (vitamin E) (John, Emte) 10. Isolation of vitamin K_2 (McKee, *et al.*) 10. Constitution and synthesis of vitamin K_1 (MacCorquodale, *et al.*) 10.

HOMER W. SMITH

Effect of female sex hormones on the guinea-pig nipple. (a) Quantitative evaluation of the local nipple test. F. Fierz. *Helv. Chim. Acta* 22, 989–98(1939).—A detailed procedure for carrying out measurements of the linear growth of the nipple of the male guinea pig by optical measurement of shadow photographs is given and the results, causes of error and advantages of the technique are discussed. The expts. recorded show that the method is suitable for the estn. of compds. contg. estrone. **(b) Hyperpigmentation after local application of female sex hormones.** *Ibid.* 999–1004.—Dropwise treatment of the nipple of male guinea pig with solns. contg. 1 γ of estrone or stilbestrol per cc. causes strong pigmentation of the nipple and the areola. The untreated nipple is not pigmented. This finding is of interest since nowadays the female sex hormones are often applied to the skin and it shows that the pigmentation may result directly without the intermediary action of the pituitary, symphysis or adrenals. It was not previously apparent that substances with female sex hormone action, unrelated chemically to estrone, could cause hyperpigmentation of the nipple and arecla. Histological examn. of nipple treated with estrone percutaneously shows, besides increase of the epithelial cells, a pronounced thickening of the epidermis with formation of numerous pigment-forming cells. C. R. Addinall

Circulation—review. R. Schoen. *Jahreskurse ärtzl. Fortbild.* 29, No. 2, 14–28(1938).—A review of recent work including the part played by sympathol, veritol, suprifen, ephetonine, benzedrine(elastonon), adrenaline, histamine, acetylcholine, insulin and various other hormones, and the adenylic acid group and some unknown substances in the circulation, as well as the behavior of the circulation and O utilization at high altitudes, and the effect of industrial poisons, as CO, benzine and benzene, of chronic Pb poisoning, and of other poisons, as alc., caffeine and nicotine, on the circulation. Ruth Berggren

The biological reaction of milk. I. The biological reaction of the milk of mothers of healthy children. Mataiti Yamamoto. *Oriental J. Diseases Infants* 23, 7(1938)(in English).—The following anaphylactic reactions occur in the isolated organs of guinea pigs which have been sensitized with 1.0 cc. milk from mothers of healthy children (MM-HC). A strip of the uterus suspended in Locke's soln. contracts when MM-HC is added to the soln. (Schultz-Dale reaction). If the heart is irrigated with Locke's soln. contg. 1% MM-HC, temporary acceleration, followed by retardation, takes place; vascular contraction appears in the coronal vascular system. If an isolated vascular prepn. of the sensitized guinea pig (Friedberger and Seidenberg, *Z. Immunitätsforsch.* 51, 276–348(1927)) is irrigated with Locke's soln. contg. 1% MM-HC, the dropping no. decreases, i. e., vascular contraction occurs. **II. The biological reaction of the milk of mothers of children with exudative diathesis.** *Ibid.* 8–9.—The anaphylactic reactions described above were more intense if carried out with the milk of mothers whose children had an exudative diathesis (MM-CED). Such differences between MM-HC and MM-CED may be important in the development of allergic manifestations in infants fed with MM-CED. **III. The biological reaction of each fraction of milk protein.** *Ibid.* 10.—Guinea pigs were sensitized with 0.02 g. casein, albumin or globulin, which had been sepd. from MM-HC and MM-CED and dried. The Schultz-Dale reaction in a strip of the isolated uterus was estd. after the incubation period. The biol. reactions of the caseins from MM-HC and MM-CED were identical. The differences in the biol. reactions of the albumins from the 2 types of milk were hardly perceptible. The globulins, especially that of MM-CED, caused the most intense reactions of the proteins studied. The difference in biol. reaction between MM-HC and MM-CED is due to differences in the globulin fraction. **IV. The qualitative and quantitative relations of globulin in the biological reaction of milk.** *Ibid.* 24, 1–2.—Guinea pigs were sensitized with 4.0 cc. of whey from various kinds of milk. The anaphylactic reaction in the isolated intestinal strip was tested 2 weeks after sensitization. The whey of MM-CED produced a weaker anaphylactic reaction than the wheys of goat mik or human colostrum but a stronger reaction than those of cow milk or MM-HC. The biol. reaction was also tested with mixts. of 1.0 cc. whey and 0.01 g. casein as the antigen; the mixt., MM-CED whey + MM-HC casein, produced a stronger anaphylactic reaction than the mixt., MM-HC whey + MM-CED casein. The differences in the biol. reaction of MM-HC and MM-CED are due to quant. and qual. differences in the globulin fraction. Ruth Berggren

Homoplastic transplantation of endocrine glands. I. Transplantation of preserved adrenal and testis. M. G. Rudits'kiĭ. *Méd. exptl.* (Ukraine) 1938, No. 1, 21–30.—Description of morphological changes following subcutaneous transplantation into patients of glands removed from fresh cadavers. S. A. Corson

The iron content of normal and trained muscles of the rabbit, chicken and the pigeon. V. G. Klimenko and P. M. Zubenko. *Méd. exptl.* (Ukraine) 1938, No. 1, 31–6.—The pectoral muscle of the chicken and pigeon and the vastus lateralis muscle of the rabbit were stimulated by Faradic shocks on one side of the animal, the muscles of the other side serving as controls. Bivalent, trivalent and org. Fe were detd. according to the Pincussen-Roman method (cf. *C. A.* 25, 2751). Normal pectoral muscles of the pigeon contained 4.3 mg. % of total Fe, those of the chicken contained 0.1 mg. %, while the m. vastus lateralis contained 1.8 mg. %. Training in the rabbit and chicken led to an increase in all the Fe fractions, while in the pigeon training increased only the org. Fe. S. A. Corson

Changes in cholesterol content and phosphate fractions of blood serum of growing rabbits. V. S. Sidorenko. *Méd. exptl.* (Ukraine) 1938, No. 1, 47–54.—Cholesterol content and the phosphate fractions (total, lipoidal and inorg.) decreased progressively during growth, the cholesterol decrease being especially marked. These changes were noted particularly during the first 2 months of postembryonic life. S. A. Corson

Muscle hemoglobin. G. A. Millikan. *Physiol. Rev.* 19, 503–23(1939).—A review article concluding that muscle hemoglobin is found in those muscles requiring vigorous repetitive activity. Its concn. increases with age. It can be crystd., is a true hemoglobin, but differs slightly from blood hemoglobin. There is no evidence for catalytic action, but it does act as a short-time O store. H. R. Getz

Fat transport in the animal body. W. R. Bloor. *Physiol. Rev.* 19, 557–77(1939).—A review article on the transport of fat from the food into the body. The transfer across placental and egg membranes is included. 104 references. H. R. Getz

Androgenic action of progesterone. L. Desclin. *Compt. rend. soc. biol.* 132, 43–5(1939).—D. was unable to detect any androgenic effects after repeated injections of progesterone in castrated male rats of various ages. L. E. Gilson

Action of sex hormones on the parathyroids of the female rat. P. Bastenie and S. Zylberszac. *Compt. rend. soc. biol.* 132, 93–4(1939); cf. *C. A.* 32, 4639[2].—Injection of folliculin caused a decrease and ovariectomy an increase in the no. of cell mitoses in the parathyroids. The successive administration of folliculin and progesterol caused a marked stimulation of the parathyroids in castrated but not in normal females. **Influence of irradiated tachysterol on the parathyroids of the female rat.** *Ibid.* 95–6.—No stimulation was detected. L. E. Gilson

Action of thyrotropic hormone on the basal metabolism of normal rabbits and rabbits which had previously ex-

hibited a period of inversion of the action of the hormone. Jacques Mahaux. *Compt. rend. soc. biol.* **132**, 97–9 (1939); cf. *C. A.* **34**, 489[7].—Thyrotropic hormone produced the same increase in metabolism in normal rabbits and the group (cf. *C. A.* **33**, 705[8]) which had shown an inverted response 4–6 months previously. **Action of serum, from rabbits with metabolism decreased by prolonged treatment with thyrotropic hormone, on the basal metabolism of normal rabbits.** *Ibid.* 99–102.—In some cases there was no apparent action; in others metabolism was slightly decreased suggesting the presence of an antibody.
L. E. Gilson

Extreme limits of the gonadotropic hormone content of human serum during normal and pathological pregnancy. Louis Gernez. *Compt. rend. soc. biol.* **132**, 111–12(1939).—In general the findings of G. confirm those of Brindeau and Hinglais (cf. *C. A.* **33**, 7808[8]). L. E. Gilson

Iron contents of various organs of dogs after intravenous injections of hemoglobin. E. Aubertin, A. Lacoste and R. Castagnou. *Compt. rend. soc. biol.* **132**, 139–41(1939).—The Fe of the liver, spleen, lungs, kidneys and pancreas increased appreciably. Little or no increase occurred in the skeletal muscles, heart, brain, stomach or intestine. L. E. Gilson

Comparative study of blood gases in dogs made acutely anemic by bleeding and subsequently treated or not by intrainjection of dog blood, solutions of dog or horse hemoglobin, or saline solution. E. Aubertin, A. Lacoste and R. Castagnou. *Compt. rend. soc. biol.* **132**, 141–4 (1939).—When hemoglobin is injected in the anemic dog it transports O satisfactorily for the first few hrs., although a considerable part of it remains in the reduced form and some is converted to methemoglobin. During the next few days it gradually disappears from the plasma.
L. E. Gilson

Dehydration and basal insulin requirement. D. B. Tyler, P. O. Greeley and D. R. Drury. *Proc. Soc. Exptl. Biol. Med.* **42**, 393–6(1939).—Depancreatized dogs on a standard diet were dehydrated by producing glucosuria along with restricted water intake. In this state the basal insulin requirement increased to more than double that of the same animals without dehydration. When they were given enough water to prevent dehydration from the glucosuria no increase in basal insulin requirement resulted.
L. E. Gilson

Effect of certain endocrines on the excretion of an antidiuretic substance. Stevens J. Martin and Herman C. Herrlich. *Proc. Soc. Exptl. Biol. Med.* **42**, 451–4(1939); cf. *C. A.* **33**, 7873[8].—Prolonged injections of large doses of theelin, progesterone, testosterone propionate and antuitrin S do not alter the ability of dehydrated rats to excrete an antidiuretic substance. L. E. Gilson

Effects of a digested hypophysis extract on reproductive tract of hypophysectomized adult male rats. R. O. Greep. *Proc. Soc. Exptl. Biol. Med.* **42**, 454–7(1939).—Tryptic digestion of anterior hypophysis ext. under suitable conditions destroys interstitial cell-stimulating activity, leaving a pure gametogenic effect in adult hypophysectomized male rats. It appears that interstitial cell stimulation and luteinization (cf. *C. A.* **33**, 7862[7]) are caused by the same substance, which is largely destroyed by such digestion.
L. E. Gilson

Mechanism of pituitary gonadotropic antagonism. Sibylle Tolksdorf and H. Jensen. *Proc. Soc. Exptl. Biol. Med.* **42**, 466–9(1939); cf. *C. A.* **33**, 6931[9], 9411[1]. The thyroid secretion exerts an antagonistic effect on the ovarian response to the pituitary interstitial cell-stimulating (luteinizing) hormone and follicle-stimulating hormone in young rats. Further expts. indicate that the pituitary thyrotropic hormone may be identical with the interstitial cell-stimulating hormone. L. E. G.

Gonadotropic activity of anterior pituitary of the finback whale. H. Jensen, E. M. K. Geiling and Sibylle Tolksdorf. *Proc. Soc. Exptl. Biol. Med.* **42**, 470–2(1939).—Three samples of Me_2CO dried whale anterior pituitary and 40% EtOH exts. thereof were assayed in normal and hypophysectomized female rats. Only follicle-stimulating hormone (FSH) was found in sample I. Samples II and III contained FSH and interstitial cell-stimulating hormone (ICSH), concurrently with luteinizing (LH), antagonistic and thyrotropic activity. Sample II had adrenotropic activity; the others were not tested for this. The alc. exts. of II and III had about the same gonadotropic activity as similar prepns. from sheep and pig pituitaries. The ICSH, LH and thyrotropic principles are believed to be identical.
L. E. Gilson

Effect of season (temperature) on blood lipides. O. B. Houchin and C. W. Turner. *Proc. Soc. Exptl. Biol. Med.* **42**, 477–9(1939).—Rabbits were kept outdoors in unprotected cages. In very hot summer weather the blood lipides ranged from 200 to 800 mg. %. In winter weather, below freezing, the range was 22–70 mg. %. Indoors in a room kept at 75–80°F. the range was 190–285 mg. %. Animals to be used for assay of the fat metabolism hormone should be kept in a temp.-regulated room.
L. E. Gilson

Lactogen content of pituitary of [illegible] and lactating rabbits and guinea pigs. Skat Holst and C. W. Turner. *Proc. Soc. Exptl. Biol. Med.* **42**, 479–82(1939); cf. *C. A.* **32**, 1310[1]; **33**, 8259[7].—In rabbits and guinea pigs the lactogen content of the anterior pituitary does not increase during early pregnancy and increases very little in the late stages of pregnancy. A distinct increase occurs after parturition. Nursing decreases and absence of nursing increases the lactogen content in both species.
L. E. Gilson

Effect of testosterone propionate on genital tract of adrenalectomized and ovariectomized immature female rats. Ira T. Nathanson and Rulon W. Rawson. *Proc. Soc. Exptl. Biol. Med.* **42**, 482–4(1939); cf. *C. A.* **33**, 8255[5].—Testosterone acts directly on the uterus and vagina and indirectly, by way of the hypophysis, on the ovaries in operatively adrenal-insufficient immature female rats. L. E. Gilson

Relation of the thyroid to creatine and creatinine excretion in the rat. J. B. Allison, C. Glaser and S. L. Leonard. *Proc. Soc. Exptl. Biol. Med.* **42**, 491–3(1939).—Thyroidectomy decreases creatine excretion and usually increases creatinine excretion; injection of thyroxine into the thyroidectomized rat has the opposite effect.
L. E. Gilson

The digestion and resorption of carbohydrates in the colon of the ruminant. A. Trautmann and Th. Asher. *Z. Tierernähr. Futtermittelk.* **3**, 45–52(1939).—In expts. with goats it was shown that starch and cellulose, brought into the cecum by means of an inserted canal, passed through the colon tract without essential change. One g. dextrose was not completely resorbed when a soln. of the sugar was introduced in the same manner. Likewise, sucrose, maltose and lactose were detected in the feces 1 hr. after introduction into the cecum. Large quantities of these sugars caused diarrhea. Liquids did not immediately pass through the colon. Introduction of large amts. of H_2O caused hematuria. High intravenous injections of dextrose led to excretion of reduced sugar through the colon. The functional peculiarity of the digestion tract of ruminants does not necessarily apply to other herbivorous species, e. g., the horse. J. O. H.

The role of cell membranes in the process of digestion of plant food products. E. L. Rozenfel'd. *J. Physiol.* (U. S. S. R.) **25**, 550–5(1938); *Khim. Referat. Zhur* **2**, No. 2, 58(1939).—The action of the amylase of saliva and of a prepn. of trypsin on ground and on whole boiled string beans was investigated. Microscopic investigation showed that the boiling process did not destroy, but only sepd. the cells and caused no pasting of starch. Approx. half of the cells were destroyed by grinding. The cell membranes were permeable to enzymes and did not suppress, but only slowed down the velocity of their activity.
W. R. Henn

The role of unilateral permeability in the intestinal absorption. D. L. Rubinshtein and V. V. L'vova. *J. Physiol.* (U. S. S. R.) **24**, 957–63(1938); *Khim. Referat. Zhur.* **2**, No. 2, 56(1939).—The intestinal tract and its blood vessels were washed simultaneously according to the method of Mond. Diffusing substances were added

to the different liquids used. The expts. proved a unilateral movement through the intestinal wall (the same for the acid as for the basic dyes) from the blood vessels into the intestinal tract, but in a direction different from the direction of the physiol. absorption. Glucose (which is actively absorbed by the intestinal wall of mammals) showed no unilateral absorption through the intestines of frogs. In the physiol. processes of intestinal absorption the unilateral permeability plays no role. The unilateral passing of the dyes in Mond's expts. is attributed to the absorption of the dye (diffused through the intestinal wall) by the endothelium of the blood vessels. W. R. Henn

The salt of synovia of cattle. S. N. Malorov. *J. Physiol.* (U. S. S. R.) **24**, 1145–9 (in German, 1149) (1938); *Khim. Referat. Zhur.* **2**, No. 2, 58–9 (1939).—The pH of synovia of cattle is < 6.90. The variations in the content of the elements, especially of Cl', are considerable. The elec. cond. is fairly const. with an av. of 93.81×10^{-3}. The f.-p. depression is expressed by the index 0.68. The values of the elec. cond. and of the f.-p. depression are higher than those for blood; therefore, the osmotic pressure in synovia must be higher. The n (av. 1.3380) and the d. (1.008) are fairly const. The η of synovia varies considerably, from 3.7 to 83.7; this is attributed to the difference in the content of mucin-like substances. W. R. Henn

Presence of histamine in the platelets of the rabbit. Leo Zon, E. T. Ceder and Catherine W. Crigler. *U. S. Pub. Health Repts.* **54**, 1978–86 (1939).—The white cells of the rabbit may be markedly depressed without significant change in blood histamine. Administration of antiplatelet serum caused a significant drop in blood histamine along with a drop in platelets. Fractional centrifugation of platelet-contg. plasma removes histamine nearly in proportion to the platelets removed. Twenty-one references. J. A. Kennedy

The fate of cholic acid in the guinea pig. Chai Heung Kim. *Z. physiol. Chem.* **261**, 97–102 (1939).—Guinea-pig bile normally contains only chenodesoxycholic acid and 3-hydroxy-7-ketocholanic acid (Imai, *C. A.* **31**, 6709[6]). After intraperitoneal injection of 18.8 g. of cholic acid (I) to 118 guinea pigs there was isolated from the combined urines 0.015 g. of desoxycholic acid (II) and 0.087 g. of I, and from the bile 0.2 g. of II. It is suggested that I is first oxidized to 3-hydroxy-7,12-diketocholanic acid, that this is then reduced to 3-hydroxy-12-ketocholanic acid and the latter reduced to II. Milton Levy

The distribution of body water and electrolytes in the intact and partially nephrectomized rat after dehydration and hydration. Alfred Chanutin, Stephan Ludewig and Geo. R. Minor. *J. Biol. Chem.* **131**, 519–38 (1939); cf. *C. A.* **32**, 9198[1].—The extracellular phase and the Cl concn. of the muscle are greater in intact rats than in those partially nephrectomized. Fasting for 24, 48 and 72 hrs. brings about an increased percentage of extracellular phase and an increased concn. of cellular H_2O in the muscle of the partially nephrectomized animals. Marked dehydration, produced by depriving the partially nephrectomized rat of food and H_2O for 24 hrs., is followed by a decrease in the cellular H_2O and a concn. of electrolytes in the extracellular phase. Intact animals show no difference in electrolyte and H_2O distribution after such treatment. Voluntary ingestion of 0.9% NaCl for 24 and 48 hrs. causes a marked subcutaneous edema and ascites in the nephrectomized animals and the intermuscular fascia of the muscle is also markedly edematous. The blood serum is hydrated and the concn. of electrolytes increased. Intact animals show comparatively small changes under similar conditions. There is also visible edema in a small percentage of the exptl. animals after voluntary ingestion of 0.4% NaCl for 72 hrs. and appreciable hydremia in all animals. Intact and partially nephrectomized rats were dehydrated by injection of isotonic glucose soln. into the peritoneal cavity. In the intact animal there was a marked shift of fluid into the muscle cells, particularly after the 5th and 6th hr. after injection. In the partially nephrectomized rats there was definite hemoconcn. and a decrease in NaCl concn. but the absolute changes in the distribution of H_2O were small and variable and in no way comparable to those noted in the intact animals. A slight decrease in the vols. of the extra- and intracellular phases during the 1st 6 hrs. followed the injection of 1.8% NaCl into the peritoneal cavity of the intact rat but under similar conditions there was an increase in the extracellular phase and a relatively marked decrease in the intracellular vol. of the partially nephrectomized animal. The results of these expts. indicate that renal insufficiency exerts an effect on the distribution of fluid in muscles. Two factors concerned are (*a*) the inability to retain or excrete H_2O and salts due to the kidney damage and (*b*) an alteration in the osmotic relationship between the muscle cells and the extracellular fluid. A. P. Lothrop

Lipoid-thiocyanate in serum. Jack D. Rosenbaum and Paul H. Lavietes. *J. Biol. Chem.* **131**, 663–74 (1939); cf. *C. A.* **30**, 7166[6].—In a series of 54 ultrafiltrations and 2 dialyses of human serum there was in every case a higher concn. of thiocyanate in the serum than in ultrafiltrate or dialyzate. Bound thiocyanate is in equil. with ionized thiocyanate of the serum. The amt. bound increased as the amt. of thiocyanate added was increased with a smaller fraction of the total bound at higher than at lower concns Increases in temp. diminished thiocyanate binding by the serum. Increases in H-ion concn. increased thiocyanate binding. The combination is loose enough to be destroyed by pptn. of the lipoids with the proteins of the serum by CCl_3CO_2H since following such pptn. recovery of SCN from the filtrate is complete. Thiocyanate is present in the petr. ether exts. of serum contg. thiocyanate although the Na salt is completely insol. in this solvent. The amt. of lipoid-SCN extd. from a given serum sample agreed well with the bound SCN detd. by ultrafiltration. Lipoid-SCN and bound SCN are also similarly influenced by temp. changes and by variations in pH. These findings furnish suggestive evidence that the chemically similar halides may exist in the same form. A. P. Lothrop

Biochemical changes associated with onset of secretory activity in the metanephros of the fetal pig. The cytochrome oxidase–cytochrome system and oxidation–reduction potentials. Louis B. Flexner. *J. Biol. Chem.* **131**, 703–11 (1939); cf. *C. A.* **33**, 1002[2].—The onset of secretory activity in the metanephros of the fetal pig is accompanied by the following changes: (1) in the presecretory structures of the metanephros, cytochrome-cytochrome oxidase activity as detd. by dimethyl-*p*-phenylenediamine and α-naphthol is feeble and is equal in epithelium and stroma. In secretory structures activity increases markedly in the epithelium and is absent from the stroma. In the presecretory structures there is no measurable oxidation-reduction potential difference between epithelium and stroma but with onset of secretion a potential difference of the order of 0.20 v. develops between them. The oxidase activity is absent or almost so in Bowman's capsule and is low in the epithelium of the collecting ducts. No potential difference was observed between the epithelium of the collecting ducts and the stroma. A. P. L.

Changes in the chloride distribution between red blood cells and plasma during the course of the general adaptation syndrome. S. Karády, H. Selye and J. S. L. Browne. *J. Biol. Chem.* **131**, 717–31 (1939); cf. *C. A.* **30**, 6444[2]; **32**, 7103[2].—It has been previously shown that if an organism is exposed to any of a variety of damaging agents, it shows certain morphological and physiol. reactions which form essentially the same syndrome irrespective of the particular agent which produces the damage. This reaction to damage has been termed "the general adaptation syndrome" and a detailed study has been made of the plasma and whole blood chlorides, hematocrit reading, hemoglobin concn. and plasma vol. to obtain accurate information regarding changes in blood chlorides during this adaption syndrome. A decrease in the concn. of chlorides in the red cells occurs immediately after cessation of treatment in rats exposed to cold or treated with subcutaneous injections of HCHO for 24 hrs. accompanied by hemoconcn. If treatment with these agents is continued for 12 days, so that the animals become adapted to them the direction of these deviations is reversed. There is an

increase in the plasma vol. and in Cl concn. in the red cells and the hematocrit and hemoglobin values are below normal. After forced muscular exercise the chlorides of the cells are above normal immediately after the cessation of the stimulus, the plasma vol. is slightly decreased and the hematocrit and hemoglobin values are slightly increased. If a 2-hr. rest period follows 24 hrs. of exposure to cold, the deviations of the 1st exposure reverse so that the cell chlorides and plasma vol. are above normal and the hemoglobin below. This reversal has not occurred 3 hrs. after the last injection of HCHO but is present after a rest period of 24 hrs. and the plasma Cl at this time is normal. If the animals are exposed to mild cold or to small doses of HCHO, the cell chlorides are increased immediately after the cessation of the treatment and show the same picture as is seen immediately after muscular exercise. If the treatment is discontinued for 24 hrs. after 12 days when the animals have become adapted to the stimulus, there is no significant change in the Cl concn., the cell chlorides remaining above the normal level. If the rats are exposed to sublethal or lethal doses of the damaging agents to which they have been adapted, the cell Cl concn. remains high in most cases although the plasma vol. may be markedly diminished and the hematocrit increased. Under the conditions of these expts. the plasma chlorides are not a good index of the changes in Cl metabolism. The red cell chlorides and the ratio between red cell and plasma Cl are more satisfactory. Marked shifts of Cl concn. in red cells may therefore occur and whole blood Cl detns. are not always merely a reflection of the proportion of cells to plasma. Special emphasis may be laid on the inverse response seen immediately after exposure to mild damage, during recovery from more severe damage and after adaptation has occurred. It appears to be the exact opposite to the 1st changes which occur after damage in these expts. and also in what is usually termed "shock." This inverse type of response has received little attention up to the present time, although it is usually connected with an increased resistance of the organism and probably reflects the establishment by the body of a compensatory mechanism against damage.
A. P. Lothrop

Content of ascorbic acid in tonsils. Mělka-Měkvá. *Acta Oto-Laryngol.* **27**, 95–6(1939)(in French).—Amygdaloid tissue is rich in ascorbic acid, especially in young individuals. Some tissue can synthesize ascorbic acid on addn. of maltose, glucose, sucrose and lactose.
J. McAfee

The action of pregneninolon on the human endometrium; by oral application. J. A. Salaber and E. B. del Castillo. *Semana méd.* (Buenos Aires) **1939, II**, 769–73.—Pregneninolon or anhydrooxyprogesterone given orally in amenorrhea of long standing produced uterine bleeding from an endometrium showing characteristic proliferation. In another case, treatment was preceded with oral doses of ethinylestradiol: the endometrium showed accentuated secretion at induced menstruation. An intercyclic menstruation in a normal woman could not be induced.
A. E. Meyer

Blood protein formation in the bone marrow. Enrico Poli. *Sperimentale* **93**, 455–62(1939).—The plasma in the marrow has a higher protein content with prevalence of the less disperse constituents. The bone marrow is considered as a place of formation of plasma proteins.
A. E. Meyer

Precipitins in antigonadotropic serums. M. Van den Ende. *J. Endocrinology* **1**, 156–71(1939).—Antiserums to an active gonadotropic ext. of pregnancy urine contain precipitins demonstrable with a variety of urinary exts. independently of their hormone activity. The amts. of precipitins present could be detd. by optimum proportions. Precipitin content and antigonadotropic power showed no const. relation to each other. Pregnancy urine exts. contain multiple antigens. Absorption of precipitins by an ext. of male urine removed all precipitins for urinary gonadotropic exts., but only partly reduced the biol. inhibitory power. Absorption of precipitins for human serum only slightly reduced the precipitins for urinary exts., and left the biol. inhibitory power completely unimpaired.
Felix Saunders

What becomes of respired free oxygen? The hydrogenotropy of oxygen. T. Thunberg. *Kgl. Fysiograf. Sällskap. Lund, Förh.* **7**, 186–98(1987)(Pub. 1938)(in German); cf. *C. A.* **32**, 7060⁶.—Various theories on biol. oxidations are discussed. In general, when atm. O_2 is inhaled it serves to oxidize the H of org. compds. in the body. The expired CO_2 arises from O already combined into compds.
W. C. Tobie

The part played by carotid body reflexes in the respiratory response of the dog to small changes in the carbon dioxide tension in the arterial blood. Carl F. Schmidt, Paul R. Dumke and Robert D. Dripps, Jr. *Am. J. Physiol.* **128**, 1–9(1939).
E. D. Walter

The effect of hypophyseal stalk transection on the gonadotropic functions of the rabbit hypophysis. Chandler McCuskey Brooks and E. F. Lambert. *Am. J. Physiol.* **128**, 57–69(1939).—Transection of the hypophyseal stalk did not interfere with reproductive activities in 6 of the 14 male rabbits operated upon. Assays of the follicle-stimulating hormone and luteinizing hormone content of the anterior lobes of male and female rabbits several weeks or months after stalk transection showed that the concn. of these hormones was comparable with that of the glands of normal control rabbits.
E. D. Walter

The response of jejunum and ileum to food and enterocrinin. M. J. Schiffrin and E. S. Nasset. *Am. J. Physiol.* **128**, 70–80(1939).—Feeding causes a decrease of both enzyme concn. and total enzyme secretion of 1st-stage jejunal and ileal segments. This inhibition is overcome in the jejunum 6 or 7 hrs. *post cibum*, but persists in the ileum for at least 8 hrs. Denervation results in an increase in enzyme concn. as well as total secretion after food which indicates that the 1st-stage inhibition was nervous in nature. The amt. of enzymes produced per unit time is greater in the jejunum than in the ileum. A reciprocal relationship exists between the Cl and total CO_2 content of succus entericus in different sections of the gut. Enterocrinin increases the concn. and amt. of enzyme secretion but does not affect the pH, Cl or total CO_2. Feeding or denervation augments the response to enterocrinin. It is effective subcutaneously when given in 10 times the amt. required for intravenous administration.
E. D. W.

The effect of occlusion of the carotids and the injection of ephedrine on the blood pressure of cats in adrenal insufficiency. R. A. Cleghorn. *Am. J. Physiol.* **128**, 133–8(1939).—Occlusion of the carotid arteries causes a marked rise in blood pressure in adrenalectomized cats even at a time when adrenal insufficiency is severe and splanchnic nerve stimulation elicits but little increase. When the circulation has become so poor that spinal reflexes become impaired, carotid occlusion fails to cause a substantial pressor effect. The effect of ephedrine on the blood pressure of the cat in adrenal insufficiency roughly parallels the degree of response obtained on splanchnic nerve stimulation.
E. D. Walter

The effect of blood flow on potassium liberation from muscle. W. O. Fenn, W. S. Wilde, Ruth A. Boak and R. H. Koenemann. *Am. J. Physiol.* **128**, 139–46(1939).—Partial or intermittent occlusion of the arterial blood supply of a muscle results in an increase in the concn. of K in the venous plasma or may cause the muscle to give out K to the blood. Excessive slowing of the circulation or complete stagnation does not increase the K more than a moderate slowing. The K which enters the blood does not cause a corresponding increase in alky. and therefore enters in exchange for some other cation or accompanied by some nonvolatile acid. Usually H_2O is taken up by the blood when the flow is diminished.
E. D. Walter

Relative cholinergic effects of selected estrogens. Samuel R. M. Reynolds and Frances I. Foster. *Am. J. Physiol.* **128**, 147–53(1939); cf. *C. A.* **32**, 6716⁷.—The effect of selected estrogens on the concn. of acetylcholine in the uterus of the ovariectomized rabbit was detd. Those used were amniotin, estradiol, estradiol benzoate and estradiol dipropionate. The artificial estrogens used were triphenylethylene and stilbestrol. Each of

these estrogens (except stilbestrol) increases within an hr. the acetylcholine content of the uterus. By the 12th hr. after injection the amt. in the uterus is distinctly less. A 2nd injection of estrogen made at the 12th hr. after the 1st injection raises again the acetylcholine content of the uterus. Esterification does not affect the capacity of the estrogen to increase the concn. of acetylcholine in the uterus within 1 hr. after injection. Triphenylethylene is as potent as any of the natural or synthetic estrogens used in its cholinergic effect on the uterus. E. D. Walter

The pH of the digestive tract in the living albino rat as determined by the capillary glass electrode. Gordon B. Ball. *Am. J. Physiol.* **128**, 175–8(1939).—The pH of the wall of the digestive tract of the living albino rat was detd. by means of the capillary glass electrode. The wall of the duodenum is rather consistently acid and the ileal and cecal walls are usually alk., while that of the colon approaches neutrality. E. D. Walter

Increased intracranial pressure and its effects during anoxia and hypoglucemia. L. Yesinick and E. Gellhorn. *Am. J. Physiol.* **128**, 185–94(1939). E. D. Walter

5,16-Pregnadiene-3,20-diol (Butenandt, Schmidt-Thomé) **10**. Exptl. correlation of the plant cardiac poisons with the estrone group (Butenandt, Gallagher) **10**.

G—PATHOLOGY

The effect of vitamins B_1 and C on anaphylactic shock. Mataiti Yamamoto. *Oriental J. Diseases Infants* **23**, 11–12(1938)(in English).—The injection of 0.25 mg. vitamin B_1 into guinea pigs before sensitization during the incubation period or several hrs. to 1 day before the shock test, checked markedly the anaphylactic shock, as estd. by the Schultz-Dale reaction of strips of the isolated uterus or intestine. The effect of vitamin B_1 may be due to its beneficial action on the liver function, preventing the formation of antibodies and removing the disturbance of the body during the sensitization period. Shock was also prevented by the injection of 100 mg. vitamin C before sensitization or several hrs. before the shock test, but it was more severe if the vitamin C was injected during the sensitization period. Vitamin C acts on the antigen *in vivo*, preventing its invasion into the tissues and hastening its removal; but, if the antigen has already invaded the body sufficiently, vitamin C intensifies the shock. Combined treatment with vitamins B_1 and C before sensitization or the shock test or during the incubation period prevents the shock. This combined treatment is beneficial to allergic patients. Ruth Berggren

Experimental studies on the function of the reticulo-endothelial system. IV. The relation between the scarlet fever toxin (Streptococcus haemolyticus) and the function of the reticulo-endothelial system. Takamaro Kitahara. *Oriental J. Diseases Infants* **24**, 5(1938)(in English).—The toxin of *Streptococcus haemolyticus* from scarlet fever patients was injected into rabbits and its effect on the reticulo-endothelial system (r. e. s.) was estd. by the Adler-Reimann method (*C. A.* **20**, 1664). Slight functional disturbances of the r. e. s. appeared which were less evident in adult than in young rabbits. Injection of the toxin into rabbits which had been immunized with anatoxin of *Streptococcus haemolyticus* produced practically no functional disturbances in the r. e. s. of either young or adult rabbits. **V. The relation between the dysentery toxin and the function of the reticulo-endothelial system.** *Ibid.* 6.—Max. disturbance of the function of the r. e. s. of rabbits appeared 6–12 hrs. after the injection of a small dose of the toxin of the Shiga bacilli and 12–24 hrs. after the injection of a large dose. In the former case the function became normal again after 3 days, in the latter after about 1 week. In the young rabbits the disturbance in the function appeared earlier and was more intense and the power of recovery was somewhat greater than in the adult rabbits. Injection of the toxin into both young and adult rabbits which had previously been immunized with the koktigen of the Shiga dysentery bacilli caused a rather marked disturbance in the function after about 6 hrs., followed by an immediate turn toward recovery. The toxin of the atypical dysentery bacilli (Y type), in general, produced the same disturbance in function as that of the Shiga type. **VI. The influence of the pneumonia bacilli on the function of the reticulo-endothelial system.** *Ibid.* 7.—Injection of the toxin of type I pneumonia bacilli into the ear vein of adult rabbits produced a max. disturbance in the function of the r. e. s. after 24 hrs., regardless of the size of the dose; a slight acceleration of the function appeared later. The max. disturbance in the function of young rabbits appeared 12 hrs. after the injection of a large dose and 6 hrs. after the injection of a small dose, followed by a marked acceleration of the function. The disturbance was greater in the adult than in the young rabbits. If type II pneumonia bacilli were used, the disturbance in the function of adult rabbits was slight and the acceleration quite marked. In the young rabbits an intense disturbance appeared 24 hrs. after a large dose and earlier after a small dose; later acceleration of the function appeared. In the case of the type II pneumonia bacilli the disturbance was smaller in the adult than in the young rabbits. **VII. The influence of the bacilli of epidemic cerebrospinal meningitis on the function of the reticulo-endothelial system.** *Ibid.* 8.—The toxin from these bacilli produced a max. disturbance in the function of the r. e. s. 6 hrs. after injection. Gradual recovery, even a slight functional acceleration, was observed after 24 hrs. The normal condition was restored in about 1 week. In the early period the disturbance in the function was marked in the young rabbits and somewhat smaller in the adult rabbits. The toxin, which was injected into rabbits, after they had been immunized with immune serum, was completely neutralized; in the young rabbits a slight acceleration in the function of the r. e. s. occurred. Ruth Berggren

The architecture of viruses. W. M. Stanley. *Physiol. Rev.* **19**, 524–56(1939).—A review article with especial attention to the measurement of virus activity, the correlation of activity with chem. and phys. properties, compn. of the viruses, crystallinity, shape and size, and the nature and mode of action of the viruses. 103 references. H. R. Getz

Provoked hyperlipemia test in diabetic patients. P. Mauriac, L. Servantie and A. Baron. *Compt. rend. soc. biol.* **132**, 145–7(1939).—In 10 diabetic patients blood lipides were detd. at intervals for 8 hrs. after ingestion of 100 cc. olive oil (no other food and no insulin given). In mild cases the changes were slight and not significant. In severe cases where the blood lipides were already high there was a slow rise for several hrs., indicating decreased tolerance. L. E. Gilson

Difference in behavior of reagins and hemolysins with respect to certain globulins. H. Bierry, M. Andrac and B. Gouzon. *Compt. rend. soc. biol.* **132**, 153–5(1939).—In human syphilitic serum the syphilitic reagins are largely found in the globulin fraction pptd. by CO_2 while the hemolysins remain in soln. with the other proteins. L. E. G.

Pancreatic secretion of patients with gastric and duodenal ulcer. P. Augier, J. Diesnis and M. Raybaut. *Compt. rend. soc. biol.* **132**, 160–2(1939).—Duodenal ulcer is frequently assocd. with a decrease in the lipase activity of the pancreatic juice. L. E. Gilson

Lack of carcinogenic potency of sulfanilamide and prontosil soluble in mice. Paul C. Zamecnik and Simon Koletsky. *Proc. Soc. Exptl. Biol. Med.* **42**, 391–2(1939).—Repeated subcutaneous injections of sulfanilamide and prontosil sol. in mice over a period of 1 yr. failed to produce any tumors. L. E. Gilson

Effect of induced hypercholesterolemia on antibody response in rabbits. Maurice R. Chassin and Maurice Bruger. *Proc. Soc. Exptl. Biol. Med.* **42**, 457–9(1939).—Hypercholesterolemia resulted in a higher agglutinin titer after treatment with typhoid vaccine. L. E. Gilson

Macromolecular components of chick embryo tissue diseased with the virus of equine encephalomyelitis. A. R. Taylor, D. G. Sharp, Harold Finkelstein and J. W. Beard. *Proc. Soc. Exptl. Biol. Med.* **42**, 462–4(1939).—Preliminary. L. E. Gilson

No platelet-destroying action in extracts of the spleen

and urine of patients with chronic thrombopenic purpura. L. M. Tocantins. *Proc. Soc. Exptl. Biol. Med.* 42, 485–6 (1939). L. E. Gilson

Blood histamine in the rabbit during anaphylactic shock. Bram Rose and Paul Weil. *Proc. Soc. Exptl. Biol. Med.* 42, 494–6(1939).—During acute anaphylactic shock in rabbits a marked decrease in total blood histamine occurs. No increase in plasma histamine is observed. L. E. G.

Effect of local applications on development of ultraviolet tumors. Harold P. Rusch, Carl A. Baumann and Bernerd E. Kline. *Proc. Soc. Exptl. Biol. Med.* 42, 508–12 (1939).—Tumors were produced in mice by ultraviolet irradiation, and during the induction period, various substances were painted on the ears where the tumors were developing. Mineral oil accelerated tumor development most rapidly, olive, cottonseed and wheat-germ oils caused slight acceleration, and linseed oil retarded tumor formation. Cholesterol in oil caused marked acceleration. H_2O_2, Bz peroxide and 1,2,5,6-dibenzanthracene were without effect. L. E. Gilson

Active immunity to pneumococci in rabbits protected by sulfapyridine. Milton Levine, W. P. Larson and Raymond N. Bieter. *Proc. Soc. Exptl. Biol. Med.* 42, 515–18 (1939); cf. *C. A.* **33**, 7892[8], 8300[7].—Rabbits were inoculated with a very virulent type II pneumococcus and saved by oral administration of sulfapyridine. After 90 days they were still immune to the type II organism and also to some other types tried. L. E. Gilson

Irradiation of cancer following injection of colchicine. M. F. Guyer and P. E. Claus. *Proc. Soc. Exptl. Biol. Med.* 42, 565–8(1939).—X-rays were markedly more lethal to bits of carcinoma from colchicine-treated rats than to similar pieces of carcinoma from untreated animals, as shown by the infrequency of "takes" when implanted. By giving colchicine to rats bearing actively growing carcinoma 15–18 hrs. before irradiation the effectiveness of the x-rays in completely destroying or retarding the growth of the cancer was increased. L. E. Gilson

Relation of skim milk feeding to cataract production. C. F. Krewson, E. J. Schantz and C. A. Elvehjem. *Proc. Soc. Exptl. Biol. Med.* 42, 573–6(1939).—Development of cataract in rats depends on the amt. of galactose consumed in the diet. Skim milk alone was not sufficiently high in lactose to cause cataract formation in the particular strain of rats used. L. E. Gilson

Effect of methylcholanthrene on latent period of breast tumors in dilute brown mice. G. Burroughs Mider and John J. Morton. *Proc. Soc. Exptl. Biol. Med.* 42, 583–4 (1939).—Painting the mice with methylcholanthrene soln. shortened the latent period of spontaneous mammary cancer. L. E. Gilson

Effects of selective salivary gland extirpation on experimental dental caries in the rat. Virgil D. Cheyne. *Proc. Soc. Exptl. Biol. Med.* 42, 587–90(1939).—Preliminary. L. E. Gilson

Gas gangrene toxin production. G. B. Reed, J. H. Orr and Mary C. Baker. *Proc. Soc. Exptl. Biol. Med.* 42, 620–1(1939).—Preliminary. L. E. Gilson

Indoluria and its relation to sulfur deficiency. Daniel H. Basinski and Geo. T. Lewis. *Proc. Soc. Exptl. Biol. Med.* 42, 628–31(1939).—Free indole was found in 22 of 275 urine samples from hospital patients. Fingernail clippings from the patients with indoluria had a normal cystine content, hence it is improbable that indoluria is due to failure of conjugation (to form indican) because of lack of available S. L. E. Gilson

The production of persistent arterial hypertension by cellophane perinephritis. Irvine H. Page. *J. Am. Med. Assoc.* 113, 2046–8(1939).—Severe persistent arterial hypertension was produced in animals by means of perinephritis induced by cellophane and silk. F. P. G.

The adrenaline content of the suprarenal glands in diphtheria intoxication. C. A. Ashford. *Brit. J. Exptl. Path.* 20, 385–9(1939).—The adrenaline content of the suprarenal glands of a series of guinea pigs rendered deeply toxemic by injection of diphtheria toxin was assayed biologically, and the results were compared with estns. on a series of normal guinea pigs. The figures were subjected to statistical analysis. The difference between the infected and noninfected animals is small, and the existence of a real difference between the 2 series is not established with a high degree of probability. The possibility of a reduction in infected animals is indicated, but in no case does this approach exhaustion of the adrenaline load. Reduction of lipoid tissue in the guinea-pig adrenal is a const. effect of diphtheria toxin, and it may be that this effect on the cortex is responsible for the depression of sympathetic action. Harriet F. Holmes

Neutralization of "purified" tumor agent suspensions by antifowl serum. R. Knox. *Brit. J. Exptl. Path.* 20, 391–6(1939).—Tumor agent suspensions apparently freed from fowl protein by differential centrifugation are neutralized by antifowl serums prepd. in goats. Neutralization occurs only in the presence of complement. The validity of a serological reaction as a test for fowl protein in "purified" suspensions depends upon the titer of the serum used. Harriet F. Holmes

A polypeptide responsible for some of the phenomena of acute inflammation. E. S. Duthie and E. Chain. *Brit. J. Exptl. Path.* 20, 417–29(1939).—A polypeptide which produces an increased permeability of the blood vessels and a leucocyte infiltration in the skin of the rabbit and guinea pig has been isolated from peptic hydrolyzates of blood fibrin. The polypeptide showed strong chemotactic effects on leucocytes *in vitro*. Polypeptide with similar properties were present in peptic hydrolyzates of a no. of proteins examd., but were not present in hydrolyzates of gelatin. The polypeptide had no demonstrable effect on smooth muscle and was nontoxic to guinea pigs. Since the polypeptide isolated had no marked vasodilator effect, it is unlikely that polypeptides are responsible for the vascular changes assocd. with tissue injury, particularly in the early stages of inflammation but must be largely responsible for the permanent increase in capillary permeability which always occurs in the later stages of inflammation after proteolysis has begun. While the biol. properties of the purified polypeptides resemble closely those of Menkin's leucotaxine (*C. A.* **33**, 717[8]), it is difficult to arrive at any definite conclusions about their chem. relationship, the field of polypeptide biochemistry being still obscure. Harriet F. Holmes

The chemical composition of the active agent of the Rous sarcoma No. 1 and of some related products. A. Pollard. *Brit. J. Exptl. Path.* 20, 429–38(1939).—The tumor-producing agent of the Rous sarcoma No. 1 can be purified by fractional centrifugation and tryptic digestion. The material contains lipoid material which has a stabilizing influence on the suspensions and protein which is considered to be essential for the activity of the prepns. Treatment with formaldehyde reduces both the activity of the prepns. and the detectable amino N, but the regeneration of the amino N has not been accompanied by an increase in the tumor-producing activity. Products derived by centrifugation from nonfilterable tumors were found to be similar in general compn. to the Rous agent although they possessed no infectivity. Materials rich in pentose nucleotides have been found to be present in high concn. in rapidly dividing cells of both plant and animal origin. The relation between the occurrence of such nuclear material and the malignant change is, however, by no means clear. It is considered that the Rous agent although consisting mainly of nucleoprotein may be more complex in character than is bacteriophage which has been found to consist almost entirely of nucleoprotein. Harriet F. Holmes

Variations in acid-base equilibrium in cancer. M. N. Pasternak. *J. méd., Ukraine* 9, 147–60(in French, 160) (1939).—The blood of patients at various stages of cancer development is alk., the pH being about 7.45, while advanced stages show a pH of 7.53. The development of intestinal polyps results in alkalosis but gastric ulcers show no abnormal variation in the acid-base equil. Similar results were observed in rabbits. S. A. Karjala

The plasma and red blood cell lipides in persistent (diabetic) lipemia and in transient (alimentary) lipemia. S. H. Rubin. *J. Biol. Chem.* 131, 691–702(1939).—In

persistent human diabetic lipemia the total plasma lipides decreased from an initial value of 23% to about 1.2% after 137 days. A linear relation was noted between the plasma carotene and phospholipide concns. In dogs with transient alimentary lipemia, there were moderate increases in plasma phospholipides and triglycerides but no change in free or total cholesterol. Both in the diabetic patient and in the dogs, the corpuscular lipides remained unchanged and within normal limits from which it is concluded that the red cells are inert in both persistent and in transient lipemia and do not participate in the transport or metabolism of fat. A. P. Lothrop

Further investigations on manic-depressive psychosis. I. Spectrographic estimation of blood electrolytes. Helgi Tómasson. *Acta Psychiat. Neurol.* **13**, 517–26(1938).—Abnormal variability occurs in manic-depressive patients, Ca values tending to be high, Na low. When possible, correction of blood electrolyte and autonomic nervous conditions by appropriate drugs disperses the psychosis and permits earlier discharge from hospital. J. McAfee

The elimination of creatine and creatinine in psoriasis. Bernhard Zorn. *Dermatol. Wochschr.* **109**, 1223–30(1939).—Creatine does not appear in the urine. A. E. Meyer

Pneumothorax gases. C. B. Weld. *Proc. Novia Scotian Inst. Sci.* **20**, 1–12(1938–39)(Pub. 1939).—Analyses of the mixts. from 15 pneumothoraxes in dogs and from 62 human patients reveal a striking difference between the human and dog results. The gas mixt. rapidly reaches an equil. and its compn. depends on the individual. In most dogs it is about 6% CO_2 and 10% O_2, while the figures in human cases vary widely; in the majority it is less than 5% O_2 and in many less than 1% O_2, with more than 7% CO_2. Possible reasons for this divergence are investigated. The duration of the pneumothorax is not a factor. A large pneumothorax may result in a slight change in the analysis in this direction, as may depression of respiration by morphine, but these are not the chief factors. Results in dogs approximating human analyses are obtained when pleural irritation and inflammation are induced by 1-cc. injections of Monsel's soln. or of 5% I_2 in 10% KI. The typical compn. of the human pneumothorax—a low O_2 and a high CO_2 concn.—is therefore apparently due to a concomitant pleural inflammation. Dorothy A. Meyer

Simmond's disease due to postpartum necrosis of the anterior pituitary. H. S. Sheehan. *Quart. J. Med.* 8, 277–309(1939).—Anterior pituitary necrosis may occur at delivery if it is complicated by collapse and severe hemorrhage. The symptoms produced by lack of anterior pituitary secretion ensue. Replacement therapy is not yet satisfactory, but if a subsequent pregnancy occurs the symptoms are permanently cured, probably because of hypertrophy of pituitary remnants. Fifty-one cases are reviewed. 81 references. John T. Myers

Experimental leucocytosis in man. N. G. Nordenson. *Quart. J. Med.* **8**, 311–21(1939).—The effects of Na nucleinate, pentose nucleotide, and in a few instances, of adenine sulfate were studied including 59 expts. on 43 patients. Both Na nucleate and pentose nucleotide induce a continuing peripheral neutrophilic leucocytosis with hastened maturation of the granular cells of the bone marrow, but only if the bone marrow was previously undamaged. No abnormal mitosis in the bone marrow was observed. If the bone marrow had been previously injured by infection or pernicious anemia these changes did not occur. 105 references. John T. Myers

A study of some serum electrolytes in hypertension. O. L. V. S. De Wesselow and W. A. R. Thomson. *Quart. J. Med.* **8**, 361–74(1939).—The serum of patients with essential, and even more markedly with malignant, hypertension tends to show a lower level of K than that of patients with a normal blood pressure, when on the same diet. Low serum Na is not infrequent in malignant hypertension. Administration of Na salts raises the blood pressure of hypertensive subjects, while K salts have the opposite effect. These alterations are slight and the amts. of salts required to produce them are not apt to be taken in a freely chosen diet. Attempts at depletion of the body Na are without effect on the blood pressure. 30 references. John T. Myers

Cholesterolysis in the blood plasma of individuals with mental disorders. Purcell G. Schube, Naomi Raskin and Eleanor Campbell. *J. Lab. Clin. Med.* **25**, 142–9(1939).—The rate of change of the total cholesterol concn. of the blood plasma of 26 male patients who were normal physically but mentally ill was studied over a period of 24 hrs. at room and ice-box temps. The results were similar to those obtained on normal individuals (*C. A.* **33**, 1378[9]) but on a lower plane. The rate at which cholesterol aggregates are able to free themselves from the meshes of protein mols. is discussed as an important factor in cholesterolysis. Howard W. Robinson

The Eagle complement-fixation test for syphilis. A note on the amboceptor titration. Allen Gold. *J. Lab. Clin. Med.* **25**, 194–5(1939).—The Eagle test (*C. A.* **31**, 2282[2]) was found inferior in sensitivity when run in parallel with an 18-hr. fixation and both Kahn and Eagle flocculation tests. When the test was modified so that the proper relationships between amboceptor and complement were assured, a high degree of sensitivity, with a specificity in excess of the requirement of the U. S. Pub. Health Service, was obtained. Howard W. Robinson

Virus problem with foot-and-mouth disease as an example. L. W. Janssen. *Chem. Weekblad* **36**, 684–8(1939)(English summary). **Cultivation of ultrafilterable viruses.** H. S. Frenkel. *Ibid.* 688–91. **Pathological botanical aspect of the virus question.** H. M. Quanjer. *Ibid.* 691. **Purification of the tobacco mosaic virus.** Ij. van Koot. *Ibid.* 691–2. **The place of virus tumors in tumor investigation.** N. Waterman. *Ibid.* 692–3.—A symposium. Felix Saunders

Glucose-tolerance tests. B. A. Watson. *Endocrinology* **25**, 845–52(1939).—The incidence of glucosuria in routine examn. of college students was 1.14%. About 15.5% of patients with glucosuria showed definitely disturbed carbohydrate metabolism. Felix Saunders

Action of dimethylaminoazobenzene on tissue culture. Syuzo Morigami. *Gann* **33**, 281–5(1939).—By adding dimethylaminoazobenzene to a culture medium in proportion of 1:10,000 a change of healthy fibroblasts into morphologically malignant cells took place. After two passages the morphological divergency begins to appear. Inoculation of these suspicious cultures into the pectoral muscle of normal hens failed to develop sarcoma. K. S.

Ketonemia in pregnant ewes and its possible relation to pregnancy disease. A. H. H. Fraser, W. Godden, L. C. Snook and W. Thomson. *J. Physiol.* **97**, 120–7(1939); cf. *C. A.* **33**, 2190[5].—Further evidence is presented of an inverse correlation between a caloric deficiency of the diet and the incidence of ketonemia in pregnant sheep. The possible significance of exptl. results to a clearer understanding of the diseases of pregnant sheep in the field is discussed. E. D. Walter

Density distribution and energy spectrum of B electrons—excitation process in cancerous cells (Schmidt) **3**.

H—PHARMACOLOGY

CARL F. SCHMIDT

The cerebellar form of lead encephalopathy. A. Biemond and S. van Creveld. *Acta Paediat.* **27**, 51–62(1939)(in English).—This form of Pb poisoning, observed in a 2-year-old girl, was caused by drinking water contaminated with Pb. Ruth Berggren

The relation of nicotinamide to porphyrin metabolism and to the action of light. Wolfram W. Kühnau. *Strahlentherapie* **66**, 24–39(1939).—Studies on 8 patients and 250 mice failed to reveal any clear relation between nicotinamide and porphyrin metabolism. From certain differences in the behavior of mice, treated with hematoporphyrin and nicotinamide, on irradiation it is probable that nicotinamide possesses a light-protective action as yet unexplained. Ruth Berggren

Treatment of heart worms in dogs with Stibsol—a new drug. Harold P. Brown and James A. Austin. *J. Am. Vet. Med. Assoc.* **95**, 566–9(1939).—Stibsol, sodium anti-

monial-3-catechol-thiosalicylate is effective in the treatment of heart-worm infestation in dogs if a certain unspecified concn. is present in the blood stream. R. Brown

Hemoglobin, reticulocytes and blood sedimentation rate in cases of therapeutic malaria and the effects of treatment of them. E. D. W. Greig and Alexander Neil. *J. Trop. Med. Hyg.* **42**, 277–81(1939). R. Brown

Inhibition of peptic digestion by coffee and sodium chloride. Th. Sabalitschka and E. Pilger. *Scientia Pharm.* **10**, 128–31(1939).—An undild. drink of coffee prepd. in the usual manner strongly inhibits peptic digestion *in vitro* and the same effect is produced by a considerably dild. coffee, coffee beans, Kaffee-Hag and Idee-Coffee; Kathreiner-malt coffee shows no such action. The effect is due both to the ingredients of the coffee and to the change of pH of the digestive liquid as a result of adsorption of gastric acid to the constituents of the coffee prepn. Caffeine in the drink is not responsible for the inhibition. NaCl in concn. of 0.25% has a noticeable inhibitory action *in vitro;* in 1% soln. a very strong one. The inhibitory action in each case is not assocd. with an irreversible change in the albumin making it permanently indigestible for pepsin-HCl mixt. 16 references. H. M. Burlage

The relation of the liver to adrenaline. G. E. Batrak and L. I. Timofeeva. *Méd. exptl.* (Ukraine) **1938**, No. 1, 55–62.—Expts. were performed on isolated livers from normal and P-poisoned rabbits. Adrenaline activity was detd. by perfusing the blood vessels of the rabbit ear (Kravkov-Pisemskiĭ technique). Both the normal and the P-poisoned livers showed no ability to destroy adrenaline. In fact, the vasoconstricting effects of adrenaline solns. which were prepd. in Ringer-Locke soln. previously perfused through the liver were markedly stronger than those prepd. in ordinary Ringer-Locke soln. Moreover, the former type of adrenaline soln. retained its activity for much longer periods than the adrenaline soln. prepd. in ordinary Ringer-Locke soln. S. A. Corson

Changes in intermediary metabolism during ether narcosis. F. N. Shterenson-Genes. *Méd. exptl.* (Ukraine) 1938, No. 1, 63–72.—Seventy-five dogs were kept under ether narcosis for 30-150 min. In all cases the blood of the narcotized dogs showed an increase in glucose, lactic acid and acetone, and a decrease in the alk. reserve and pH. These changes were apparent after 10 min. of etherization, reached a max. at the end of administration of ether, and returned to normal 4–24 hrs. after ether was discontinued. They can probably be ascribed to the accompanying anoxemia. S. A. Corson

The influence of surgical operations on the acid-base equilibrium of the blood. R. B. Kremerman. *Méd. exptl.* (Ukraine) **1938**, No. 1, 73–80.—The alkali reserve (Van Slyke method) was detd. before and 3–48 hrs. after operations on 19 patients under general anesthesia and 53 patients under local anesthesia. In all cases there was a decrease in the alk. reserve during the postoperative period, this decrease being more marked in patients who exhibited some acidosis before the operation. Preoperative alkali administration is therefore recommended. S. A. Corson

The effect of toxemia on metabolism. Eric Holmes. *Physiol. Rev.* **19**, 439–71(1939).—A review of the literature on the effect of toxemia on metabolism with especial consideration of carbohydrate metabolism. 113 references. H. R. Getz

The present status of the barbiturate problems. A. L. Tatum. *Physiol. Rev.* **19**, 472–502(1939).—A review article presenting the more recent knowledge of the pharmacology of the barbituric acid derivs. 187 references. H. R. Getz

Influence of diethylaminoethoxydiphenyl (F 1262) and corynanthine on adrenaline-benzene cardiac fibrillation. T. C. R. Shen. *Compt. rend. soc. biol.* **132**, 52–4(1939); cf. *C. A.* **32**, 9260⁴.—In dogs corynanthine exerts a prolonged protective action against the fibrillation. The protective action of F 1262 is weak and very transient. L. E. Gilson

Characteristic changes in the electroencephalogram produced by narcosis. Z. Drohocki and J. Drohocka. *Compt. rend. soc. biol.* **132**, 64–9(1939); cf. *C. A.* **33**, 2212¹.—Effects of evipan, dial and Et_2O on the frequencies of the waves are described. L. E. Gilson

Mydriatic action of adrenoxine. P. Heirman and M. Goffart. *Compt. rend. soc. biol.* **132**, 84–5(1939).—The mydriatic activity of adrenoxine is about 10,000 times that of adrenaline. A 1:100,000 soln. produces a market effect in the eye of the frog, guinea pig, dog or man. L. E. Gilson

Action of sodium glucuronate in the prophylaxis of benzopyrene cancer. J. Maisin, Y. Pourbaix and C. Van de Voorde. *Compt. rend. soc. biol.* **132**, 86–7(1939).—Oral or parenteral administration of small repeated doses of Na glucuronate seemed to have an appreciable inhibiting action on the development of cancer after the application of benzopyrene to the skin of mice. L. E. Gilson

Pharmacodynamic study of phenyltyramine. A. Lespagnol and G. Bizard. *Compt. rend. soc. biol.* **132**, 103–6 (1939).—In dogs the intravenous injection of 10 mg./kg. of α-phenyltyramine-HCl, $HOC_6H_4CH_2CH(Ph)NH_2.HCl$, causes a transient decrease in arterial pressure equiv. to 20–30 mm. Hg, a decrease in kidney vol. and a short period of apnea. A $^1/_{15,000-30,000}$ soln. decreases both the tone of isolated rabbit intestine and the amplitude of its contractions. L. E. Gilson

Action of carbaminoylcholine, geneserine and acetylcholine-geneserine mixture on the thyroid gland. G. Carrière, J. Morel and P. J. Gineste. *Compt. rend. soc. biol.* **132**, 113–14(1939).—In young rabbits the repeated injection of large doses of any of the above mixt. produced marked hypertrophy of the thyroid. L. E. Gilson

Attempted isolation of the toxic substance present in extract of Ascaris megalocephala. Some properties of the toxin. M. A. Macheboeuf and R. Mandoul. *Compt. rend. soc. biol.* **132**, 124–6(1939); cf. *C. A.* **33**, 5503⁴.—The substance was not isolated. It is sol. in 50% EtOH. It is inactivated by boiling a few min. or by storing the slightly acid soln. in the refrigerator a week. **Biological properties of the toxin of Ascaris megalocephala.** R. Mandoul. *Ibid.* 126–8.—The toxin extd. by CCl_3CO_2H soln. has no antigenic properties. L. E. Gilson

Toxicity of the fluke, Fasciola hepatica. R. Mandoul. *Compt. rend. soc. biol.* **132**, 128(1939).—Ext. of the sheep liver fluke is not toxic to guinea pigs. L. E. Gilson

Toxic action of hemoglobin injected intravenously in dogs. E. Aubertin, A. Lacoste and R. Castagnou. *Compt. rend. soc. biol.* **132**, 129–31(1939).—The injection of 3.5% solns. of dog or horse hemoglobin produced no significant symptoms but solns. 7% or stronger often produced nephritis, sometimes severe enough to cause death. **Experimental production of nephritis by hemoglobin.** *Ibid.* 132–4. **Renal elimination of injected hemoglobin.** A. Lacoste, E. Aubertin and R. Castagnou. *Ibid.* 135–6. **Fate of eliminated hemoglobin products fixed in the kidneys and the histopathological reactions provoked by this fixation.** *Ibid.* 137–8.—After intravenous injection of hemoglobin granules of a heme pigment become fixed in the kidney tissues and cause degeneration of the epithelial cells. L. E. Gilson

Effect of analeptic drugs on hibernation in the thirteen-lined ground squirrel (Citellus tridecemlineatus). Carl Pfeiffer, Mark A. Foster and David Slight. *J. Pharmacol.* **67**, 307–12(1939).—The sympathicomimetic amines are the most potent analeptics against the hibernating state. During hibernation clonic convulsions are well tolerated and may not awaken the animal; spinal convulsions are poorly tolerated and sensitivity to spinal convulsants is greatly increased. Metrazole, picrotoxin and cocaine have high analeptic indexes in hibernation. Caffeine sensitizes the hibernator so that handling produces a tetanic convulsion which may be immediately fatal. Coramine is twice as toxic in hibernation and produces a sen-

sitization lasting several days during which the animal, if touched, goes into clonic convulsions which may continue 2–3 days ("marathon convulsions") and kill the animal by exhaustion, but which can be stopped by ephedrine which awakens the animal. Strychnine is 10 times as toxic in the hibernating as in the awake animal. The hibernating animal is a good test animal for the study of acidosis and the effects of vasoconstricting and metabolism-stimulating drugs. L. E. Gilson

Effects of sedatives, narcotics and anesthetics on changes in the body water of frogs produced by pituitrin. Eldon M. Boyd, K. J. Clark and Austin E. Smith. *J. Pharmacol.* **67**, 313–20(1939).—Et_2O, $CHCl_3$ and anesthetic doses of Na phenobarbital depressed pituitrin water uptake in frogs. Similar results were obtained with all other sedative and narcotic drugs tried. L. E. Gilson

Electrical studies on the pharmacology of autonomic synapses. III. Action of ephedrine analyzed by a study of its sympathetic central and ganglionic effects. Amedeo S. Marrazzi. *J. Pharmacol.* **67**, 321–9(1939); cf. *C. A.* **33**, 4674⁴.—Increased preganglionic potentials show that ephedrine activates sympathetic cells within the central nervous system, while decreased postganglionic potentials show that it blocks sympathetic ganglia and annuls the effect of central sympathetic stimulation. The possible mechanism of the action is discussed. L. E. Gilson

Hypoglucemic activity of globin insulin. L. Reiner, D. S. Searle and E. H. Lang. *J. Pharmacol.* **67**, 330–40 (1939); cf. *C. A.* **33**, 7487⁴.—The prepn. contained about 3.8 mg. beef globin and 0.3 mg. Zn per 100 units insulin. It was completely sol. at pH 4 but pptd. at pH 5–8 with max. flocculation at pH 6.1. The soly. was modified by the presence of various salts. The hypoglucemia produced lasted more than twice as long as that produced by an equiv. amt. of ordinary insulin. Decreasing the Zn or globin content shortened the duration of action. The antigenic action was extremely slight. Exptl. prepns. made with rabbit and human globin gave about the same results as beef globin insulin. L. E. Gilson

Calcium ions necessary to synaptic transmission in parasympathetic, not in sympathetic, ganglia. Geo. D. Shafer. *J. Pharmacol.* **67**, 341–52(1939).—The parasympathetic paths to the sphincter pupillae of the cat are temporarily paralyzed by proper injections of Na citrate, but the sympathetic pathways to the constrictor musculature of the visceral blood vessels, to the chromaffin cells of the adrenal medulla, to the dilator pupillae, or to the retractor smooth muscle of the nictitating membrane are not. Perhaps the synapses in cholinergic ganglia are of 2 classes, Ca-cholinergic and K-cholinergic. L. E. G.

Distribution and rate of elimination of picrotoxin. Dorotha M. Duff and James M. Dille. *J. Pharmacol.* **67**, 353–7(1939); cf. *C. A.* **33**, 742⁸.—In rabbits and dogs, after injection of 5 mg./kg. doses of picrotoxin there is an immediate rapid fall in blood picrotoxin which levels off after about 20 min. Analyses of liver and muscle show that much of the drug is taken up by the tissues and eliminated later. Two hrs. after the injection the concn. of picrotoxin in the blood is biologically negligible (less than 0.02 mg. %). This means that when it is used in treatment of barbiturate poisoning frequent administration is necessary to maintain effective concns. L. E. G.

Retention and excretion of selenium after the administration of sodium selenite to white rats. Ross A. Gortner, Jr., and Howard B. Lewis. *J. Pharmacol.* **67**, 358–64(1939).—Young rats were fed synthetic diets contg. Na_2SeO_3 at levels of 25, 35 and 50 p. p. m. of Se. Their growth was stunted. The Se content of the combined liver, kidneys and spleen of individual rats so fed for long periods ranged from 0.03 to 0.17 mg. or from 0.4 to 2.48% of the Se ingested. There was no correlation between the Se concn. of the diet and that of the organs. Ingested Se in the form of Na_2SeO_3 is rapidly eliminated by rats. From 20 to 50% of that ingested was found in the feces. L. E. Gilson

Procaine base dissolved by means of carbon dioxide and its mode of action. R. Beutner. *Proc. Soc. Exptl. Biol. Med.* **42**, 380–2(1939).—Procaine base was suspended in water heated to the m. p. of the base, 59°, and CO_2 passed in until the base dissolved. This soln. was only slightly more convulsant than an equiv. soln. of procaine-HCl but was much more anesthetic on topical application. L. E. Gilson

Influence of hypochloremia on convulsive reactivity. E. Spiegel and H. Wycis. *Proc. Soc. Exptl. Biol. Med.* **42**, 400–3(1939).—In rabbits and cats hypochloremia increased the convulsive reactivity to elec. stimulation through the eyeballs. L. E. Gilson

Negative effects of cysteine hydrochloride on regression of carcinoma in line A albino mice. E. Elizabeth Jones. *Proc. Soc. Exptl. Biol. Med.* **42**, 403–5(1939).—Cysteine-HCl injected directly into spontaneous and inoculated carcinoma caused necrosis and extrusion of necrotic material but produced permanent regression in only one of 20 mice treated. Partial regression of any one tumor was without effect on the growth of other untreated tumors on the same mouse. L. E. Gilson

Some effects of anesthetic mixtures dissolved in oil on motor nerves in the cat. Donald Duncan. *Proc. Soc. Exptl. Biol. Med.* **42**, 405–7(1939).—Local anesthetic mixts. were dissolved in vegetable oil and injected into the subcutaneous tissues of the face in cats. Paralysis of the orbicularis oculi muscle lasting 1–21 days was produced by solns. contg. procaine base or nupercaine-HCl (with benzyl alc. and other ingredients). Degeneration of the facial nerve fibers occurred in every case. The oil alone caused no damage. L. E. Gilson

Effect of sulfapyridine in pneumococcus type I infection in rabbits. W. P. Havens, L. P. Hansen and Cecelia G. Kramer. *Proc. Soc. Exptl. Biol. Med.* **42**, 408–10(1939).—A blood level of 7–10 mg. % total (free plus conjugated) sulfapyridine was effective in curing ⅔ of the treated rabbits. The temps. of the treated rabbits were 1–2° lower than those of untreated infected controls. L. E. Gilson

Toxicity of sulfathiazole and sulfapyridine. H. B. van Dyke, R. O. Greep, Geoffrey Rake and C. M. McKee. *Proc. Soc. Exptl. Biol. Med.* **42**, 410–16(1939).—The toxicity (LD 50) of Na sulfathiazole (2-*p*-aminobenzenesulfonamidothiazole) (I) is about 65% of that of Na sulfapyridine (II). Repeated administration of the drugs in the food of mice shows that I is more toxic than II at high dose level but not at the therapeutic dose level. In monkeys and growing rats, given either drug for 14–17 days, II is clearly more toxic. The principal pathol. changes are kidney damage. I is more rapidly excreted and undergoes much less conjugation than II. L. E. G.

Therapeutic effect of sulfathiazole and sulfapyridine. C. M. McKee, Geoffrey Rake, R. O. Greep and H. B. van Dyke. *Proc. Soc. Exptl. Biol. Med.* **42**, 417–21 (1939).—When administered as 1% of the diet the therapeutic action of sulfathiazole (2-*p*-aminobenzenesulfonamidothiazole) is equal to that of sulfapyridine, in mice infected with pneumococcus or meningococcus. Both gave complete protection from hemolytic streptococcus and both had an appreciable therapeutic action against the agent of venereal lymphogranuloma. Neither showed any activity against swine influenza virus or herpes simplex. L. E. Gilson

Chemotherapeutic evaluation of sulfanilamide derivatives of heterocyclic amines. Frank B. Cooper, Paul Gross and Marion Lewis. *Proc. Soc. Exptl. Biol. Med.* **42**, 421–5(1939).—In mice inoculated with 1000–10,000 fatal doses of streptococcus, 2,6-diamino-3-*p*-sulfonamidophenylazopyridine (I) saved only 20% while 2-*N*-4-acetylsulfanilamido-6-aminopyridine (II), 2-sulfanilamido-6-aminopyridine, 2-sulfanilamidothiazole, 2-sulfanilamido-4-methylthiazole, sulfanilamide and sulfapyridine saved 60–90%, the effectiveness increasing in the order named. In type II pneumococcus infection of mice I and II were of no value while the other compds. saved 40–60%. L. E. Gilson

Effect of repeated injections of cobra venom and morphine on behavior of rats in a maze. Moses B. Macht. *Proc. Soc. Exptl. Biol. Med.* **42**, 433–6(1939). Behavior

of rats in a maze in relation to analgesic effects of cobra venom and morphine. *Ibid.* 436–8.—Preliminary notes. L. E. Gilson

Sugar alcohols. XIX. Relationship between chemical constitution and speed of hemolysis. Anne Mary Kunkel, C. Jelleff Carr and John C. Krantz, Jr. *Proc. Soc. Exptl. Biol. Med.* 42, 438–40(1939); cf. *C. A.* 33, 7385[9].—Unbuffered solns. of the compds. isoösmotic with blood were used. The pH ranged from 6.9 to 7.2. Ethylene glycol, ethylene oxide, glycerol and epihydrin alc. rapidly hemolyzed dog corpuscles. With erythritol hemolysis was slow, but that produced by its anhydride, erythritan, was rapid. Sugar alcs. contg. 5 and 6 C atoms and their monoanhydrides (pentaerythritol, arabitol, mannitol, mannitan, styracitol, sorbitol, sorbitan, polygalitol, dulcitol, inositol and pinitol) hemolyzed the corpuscles very slowly (75–240 min.) but the double anhydrides isomannide and isosorbide hemolyzed them in a few seconds. All the hemolytic phenomena were osmotic in character and not erythrolytic. L. E. Gilson

Effect of parenteral liver extract on the fission rate of Paramecium caudatum. Austin R. Middleton and George E. Wakerlin. *Proc. Soc. Exptl. Biol. Med.* 42, 442–4(1939).—Low concns. had no effect and higher concns. retarded fission. The method has no value as a bioassay for the antipernicious anemia principle. L. E. Gilson

Amino acid nitrogen in urine of children with the nephrotic syndrome following intravenous amino acids. Lee E. Farr and Douglas A. MacFadyen. *Proc. Soc. Exptl. Biol. Med.* 42, 444–6(1939).—There was no significant immediate increase in the urinary excretion of nonprotein N, urea plus ammonia N, nor amino acid N, by 4 nephrotic children aged 5–7 yrs. who had received intravenously 5 g. of an amino acid mixt. from casein hydrolyzed by enzymes; therefore it seems probable that the amino acids were utilized for nutritional needs. L. E. Gilson

Effect of pyocyanine on cerebral metabolism. J. F. Fazekas, Harriet Colyer, Sarah Nesin and H. E. Himwich. *Proc. Soc. Exptl. Biol. Med.* 42, 446–8(1939).—Preliminary. L. E. Gilson

Glucuronic acid produced by surviving slices of liver from animals poisoned with phosphorus or chloroform. Ernest Bueding and Peter Ladewig. *Proc. Soc. Exptl. Biol. Med.* 42, 464–5(1939); cf. *C. A.* 33, 1801[4], 8748[2].—P poisoning impaired the ability to form glucuronic acid, $CHCl_3$ poisoning did not. L. E. Gilson

Alkyl nitrites. V. Pharmacology of alkyl nitrites of high molecular weight. John C. Krantz, Jr., C. Jelleff Carr and Sylvan E. Forman. *Proc. Soc. Exptl. Biol. Med.* 42, 472–4(1939); cf. *C. A.* 33, 741[9].—Inhalation of the vapors of hexyl, heptyl, octyl and (2-ethyl)hexyl nitrites produced a marked fall in blood pressure in dogs. The effects of nonyl and decyl nitrites were much less marked. Dodecyl, (5-ethyl)nonyl, (7-ethyl-2-methyl)-undecyl, tetradecyl, hexadecyl and octadecyl nitrites, because of their low vapor pressures, produced little or no effect when inhaled, but when dissolved in a hydroalc. solvent and injected intravenously they elicited full depressor responses. The min. effective vapor pressure for the series, 0.5 mm. at 28°, is exhibited by decyl nitrite. The optimum vapor pressure is between 3 and 4 mm. (heptyl nitrite); higher vapor pressures give rise to compds. which produce an unnecessary amt. of methemoglobin in the blood, and, owing to low oil soly., produce a transient response. L. E. Gilson

Comparison of the influence of anoxia and asphyxia on blood sugar. E. Gellhorn and A. C. Packer. *Proc. Soc. Exptl. Biol. Med.* 42, 475–7(1939).—In unanesthetized rabbits the inhalation of 5.4% CO_2 has practically no effect on blood sugar when used alone but greatly increases the production of hyperglucemia in inhalation of 7% O_2. L. E. Gilson

Effect of cyanide on cerebral metabolism. J. F. Fazekas, Harriet Colyer and H. E. Himwich. *Proc. Soc. Exptl. Biol. Med.* 42, 496–8(1939).—In dogs the intravenous or intracarotid injection of KCN causes a decrease in cerebral O consumption proportional to the KCN concn. Concns. which inhibit cerebral respiration cause no significant decrease in the O consumption of skeletal muscles. Discussion. L. E. Gilson

Do alkalies used in the treatment of peptic ulcer cause kidney stones? Herman L. Kretschmer and Ralph C. Brown. *J. Am. Med. Assoc.* 113, 1471–5(1939).—The difference of 1.8% in the incidence of stone formation between individuals who were given alkalies in the treatment of peptic ulcer and those who were not is not significant. F. P. Griffiths

The treatment of pneumococcic meningitis with sulfapyridine. Horace L. Hodes, Harry S. Gimbel and Geo. W. Burnett. *J. Am. Med. Assoc.* 113, 1614–19(1939).—Intravenous use of a 5% soln. of the Na salt of sulfapyridine permits better control of the concn. in the blood. An initial dose of 0.1 g. per kg. body wt. followed every 6 hrs. by 0.03 g. per kg. is combined with oral administration of 1 to 12 g. per day. A spinal fluid concn. of between 10 and 15 mg. of sulfapyridine per 100 ml. should be maintained. F. P. Griffiths

Experimental chemotherapy with sulfanilamide and related compounds. Sanford M. Rosenthal. *J. Am. Med. Assoc.* 113, 1710–14(1939); cf. *C. A.* 33, 2994[8].—Review of relation of chem. structure to therapeutic action. Numerous references. F. P. Griffiths

Desoxycorticosterone esters. Certain effects in the treatment of Addison's disease. Joseph W. Ferrebee, Charles Ragan, Dana W. Atchley and Robert F. Loeb. *J. Am. Med. Assoc.* 113, 1725–31(1939).—Administration of desoxycorticosterone esters caused retention of Na and water and marked improvement in patient's condition. No effect on carbohydrate metabolism was noted. F. P. Griffiths

A new method of treatment of subacute bacterial endocarditis. Saul R. Kelson and Paul D. White. *J. Am. Med. Assoc.* 113, 1700–2(1939).—Patients were given 4 to 6 g. sulfapyridine daily and after 4 to 7 days treatment 15 to 25 drops per min. of heparin soln. contg. 20 units per ml. was given by uninterrupted intravenous drip. Venous clotting time was maintained at approx. 1 hr. (normally about 20 min.). Heparin treatment continued for 14 days and sulfapyridine for 4 weeks. Patients were kept well satd. with ascorbic acid. Three of 7 patients showed striking improvement and freedom from recurrence of the disease. F. P. Griffiths

Significance of the excretion of lead in the urine. Lawrence T. Fairhall. *U. S. Pub. Health Repts.* 54, 2016–19 (1939).—Presence of Pb in the urine indicates Pb absorption only and in the absence of other signs and symptoms is of itself insufficient diagnostic evidence of Pb poisoning. Eleven references. J. A. Kennedy

Studies in chemotherapy. XI. Antibacterial action of phosphorus compounds. Preliminary report. Hugo Bauer and Sanford M. Rosenthal. *U. S. Pub. Health Repts.* 54, 2093–5(1939); cf. *C. A.* 34, 163[1].—The Na salt of 4-dimethylaminophenylphosphonous acid (I) and of tris(4-dimethylaminophenyl)phosphine (III) were inactive. The secondary compd. bis(4-dimethylaminophenyl)phosphinous acid (II) administered by mouth or subcutaneously was active against streptococcal infections in mice. The activity was equal to that of sulfanilamide. The effect upon pneumococcus (Type I) infections in mice, as with sulfanilamide, was much less pronounced. The max. tolerated dose of II was 2 g. per kg orally or subcutaneously. For I orally it was greater than 8 g. per kg, and for III greater than 4 g. per kg. No evidence of delayed toxic effects has been seen. J. A. Kennedy

Effect of adrenaline on convulsions. E. Gellhorn, C. W. Darrow and L. Yesinick. *Arch. Neurol. Psychiat.* 42, 826–36(1939).—Adrenaline in doses of 0.004 to 0.015 mg. per kg. body wt. injected intravenously in rabbits temporarily inhibited insulin and metrazole convulsions, blood sugar remaining unchanged. In cats under chloralose anesthesia, hyperreflexia due to the narcotic was abolished. Adrenaline in small doses induced sleep in rabbits awakened from Na barbital sleep by metrazole, but larger doses increased metrazole convulsions. The

anticonvulsant action is linked with the carotid sinus and depressor reflexes. G. H. W. Lucas 1

Acute toxic nephritis due to inhalation of carbon tetrachloride fumes. M. A. Simon. *Can. Med. Assoc. J.* **41**, 580–3(1939).—The inhalation of concd. CCl_4 vapors produced an acute toxic degenerative nephritis. Liver damage appeared to be less than when the poison is swallowed. G. H. W. Lucas

The poisonous action of various benzenearsonic acids. Tyuiti Tomita. *Folia Pharmacol. Japon.* **27**, 205–15 (Breviaria 25–6)(1939).—Six derivs. were studied in mice; they were administered subcutaneously, intravenously and by stomach tube. The 3-nitro-4-hydroxy deriv. by stomach was more poisonous than all others given thus, but the 3-benzylamino-4-hydroxy compd. by injection was even more toxic. The toxic symptoms were usually shaking of the head, running backwards, dragging themselves in circles, loss of appetite and wt. and loss of eyesight. **The poisonous action of sodium *o*- and *p*-hydroxybenzenearsonate.** *Ibid.* 216–20(Breviaria 26).—These 2 derivs. gave symptoms similar to those described above. The *o*-deriv. was the more toxic of the 2. G. H. W. L. 2 3

The actions of some new nonalkaloidal antispasmodics on the plain and leech muscles, described and compared with those of atropine and papaverine. II. The action on the excised rabbit uterus, ox bronchial and the leech muscle. Tadamitu Yosida. *Folia Pharmacol. Japon.* **27**, 221–34(Breviaria 26–7)(1939); cf. *C. A.* **33**, 8808[8].—In descending order the following drugs were effective in decreasing acetylcholine spasm in excised rabbit uterus and ox bronchial muscle: atropine, papaverine, trasentin, 2-methyl-6-benzylaminoheptene-HCl (B-O), dibenzylacetic acid, benzylmethylaminoethyl ester-HCl (B-Tr) and octinum. In decreasing Ba spasm the order was papaverine, trasentin, B-Tr, B-O, atropine and octinum. In relaxing nicotine spasm in leech muscle the order was atropine, morphine, papaverine, trasentin, B-Tr, B-O and octinum. G. H. W. Lucas 4 5

The toxicity changes in various arsphenamine preparations through oxidation and the increased toxicity following exposure of such solutions to air. I. Spectrographic changes and the relationship between the quantity of oxygen absorbed by the solution of arsphenamine base during oxidation and the quantity of phenylarsenic oxide formed thereby. Koeki Kondo. *Folia Pharmacol. Japon.* **27**, 235–49(Breviaria 27–9)(1939).—Aq. solns. of arsphenamine base on standing show a ppt. and the absorption band in the spectroscope shows a shorter wave length. The amt. of phenylarsenic oxide formed at first is almost proportional to the O_2 absorbed, but on long standing the amt. of O_2 absorbed is much greater than the theoretical, suggesting the formation of other compds., as well as phenylarsenic oxide. G. H. W. Lucas 6 7

Pharmacologic studies on the movement of the stomach in situ. I. Action of acetylcholine. Eniti Yamao. *Folia Pharmacol. Japon.* **27**, 250–9(Breviaria 29–30)(1939).—The motor activity of the stomach in cats and rabbits was studied by placing a balloon in the stomach *in situ* and connecting it to a tambour which recorded on a kymograph. Acetylcholine produced increased activity, then almost complete cessation of movement; a delayed increase in activity was also noted. Injection of atropine in rabbits followed by an injection of acetylcholine caused only a slight relaxation. After section of the splanchnics, acetylcholine produced normal inhibitory effects, but after removal of the adrenals only stimulant effects were observed. G. H. W. Lucas 8

Experimental investigation on the action of certain Formosan snake poisons on carbohydrate metabolism. V. The influence of antiserum on the blood sugar in rabbits poisoned with snake poisons. Togaku Ri. *Folia Pharmacol. Japon.* **27**, 260–9(Breviaria 30–2)(1939); cf. *C. A.* **33**, 8808[1]. **VI. The altered influence on blood sugar of certain crotalus snake poisons after the production of habituation to these poisons.** *Ibid.* 280–91(Breviaria 33–4).—**An extensive study on the effects of snake poisons in rabbits.** G. H. W. Lucas 9

Studies in the insulin treatment of dementia precox. Charles F. Read, Gert Heilbrunn and Erich Liebert. *J. Nervous Mental Disease* **90**, 747–56(1939).—A review. G. H. W. Lucas

The chrono-inotropic action of the glucosides of Digitalis lanata on the human myocardium in myocardial insufficiency. Pietro Occhioni. *Arch. sci. med.* **68**, 245–80 (1939).—The inotropic effects are superior to those obtained with the glucosides of *Digitalis purpurea* (I) and in intensity, if not in rapidity, comparable to those of K strophanthin (II). The direct or indirect chronotropic effect is superior to that of II and slightly inferior to I. In intensive medication as well as in maintenance treatment an optimum relationship of chronotropic and inotropic effects is obtained. The neg. bathmotropic effects as observed with I (extrasystoles) are extremely rare with *D. lanata*. The neg. dromotropic effect on the bundle of His, clinically valuable in auricular fibrillation, is slightly inferior to that of I but better than II. *Digitalis lanata* is the preferred medication in insufficiency of the right as well as of the left heart. II has only a preference for temporary medication when quick action is imperative. The lanata glucosides are well tolerated and a cumulative effect is unlikely. They can be given intravenously, intramuscularly (painless) and *per os*, without upsetting the stomach. A. E. Meyer

A case of nephrosis caused by trypaflavine. Antonio Malaguti. *Arch. sci. med.* **68**, 305–38(1939).—Report of the case of a girl 14 yrs. old treated for endocarditis with intravenous injections of a 0.5% soln. A total of 0.1125 g. was given in 5 days. Albuminuria (1.4%) oliguria and moderate N retention were present. Cessation of treatment was followed by complete recovery within 40 days. A. E. Meyer

The action of oligodynamic waters and of some preparations of colloidal metals on experimental infection with Castellanella brucei. S. Biozzi. *Riv. parassitologia* **2**, No. 2(1938); *Rev. sud-americana endocrinol. inmunol. quimioterap.* **22**, 631.—Of 14 guinea pigs infected with *Castellanella brucei* and treated with H_2O kept in contact with metals (Cu, Zn, Pt) only one survived. Certain colloidal metal prepns. (zymocuprol, cupridol) seemed to have some curative effect. A. E. Meyer

Rhodium salts and syphilis. E. Paravanati. *Giorn. ital. dermatol. syphilol.* **79**, No. 4(1938); *Rev. sud-americana endocrinol. inmunol. quimioterap.* **22**, 633–4.—The Cl salts of Rh and Rh with Li, K and Na were tested for their usefulness in syphilis treatment. While *in vitro* no effect on spirochetes was observed a good therapeutic effect was obtained in rabbits infected with syphilis. The drugs were well tolerated. A few human cases treated gave favorable responses, but the no. was too small to be convincing. A. E. Meyer

Anatomical lesions following injections of dinitrophenylmethylglyoxalidine in large dosage. Enrique F. Cantilo. *Semana méd.* (Buenos Aires) **1939**, II, 773–80.—A 1% soln. was injected into rabbits. A single dose exceeding 0.05 to 0.07 cc. per kg. caused death within a few hrs. with asphyxia, convulsions and hyperthermia. If smaller doses were given repeatedly, the animals showed at autopsy congestion and degeneration of the liver, damage to kidneys and myocardium and pulmonary congestion. If the treated animals were not killed they survived without apparent detrimental aftereffects. A. E. Meyer

Action of drugs on the nasal mucosa. Arthur W. Proetz. *Arch. Otolaryngol.* **30**, 509–15(1939).—The actions of various drugs were noted on ciliary activity in the nasal mucosa, both *in vivo* and excised. Benzedrine inhalers, both with and without oil of lavender, caused no change in the amplitude or speed of the beat of the cilia. Direct application of benzedrine sulfate, however, in 1%, 2% or 3% soln., stopped ciliary motion for a few min. Alc., either 18% or 20%, stopped the ciliary beat immediately. Wetting agents, such as 0.01% decylbenzene Na sulfonate and 0.01% monobutyl diphenyl Na monosulfonate, cause slowing of the ciliary beat. These drugs in a 0.1% soln. disintegrate the cilia. Ether and chloroform vapor have no effect on the cilia, but if applied in

liquid form, stop ciliary beat. N_2O has no effect on the cilia of the nasal mucosa. Dorothy A. Meyer

An attempt to condition gastric secretion to histamine. S. Katzenelbogen, Roger B. Loucks and W. Horsley Gantt. *Am. J. Physiol.* **128**, 10–12(1939); cf. *C. A.* **31**, 8702[7].—Conditioning cannot take place if the unconditioned stimuli which provoke the phenomenon to be conditioned exercise their specific actions through the peripheral and not through the central nervous system. E. D. Walter

New results on the absorption of insulin from the alimentary tract. L. E. Young, W. A. Phillips and J. R. Murlin. *Am. J. Physiol.* **128**, 81–91(1939); cf. *C. A.* **32**, 9974.—Nearly 300 expts. on 10 dogs. have confirmed the favoring effect of hexylresorcinol in alk. soln. on the absorption of insulin from the alimentary tract. The heptyl and octyl resorcinols also have this property. The optimum pH range of the mixt. for max. effect on intragastric administration is from 9.9 to 10.5. Insulin protected by hexylresorcinol survives incubation for one-half hr. with trypsin Unless the soln. is boiled before injection, however, the trypsin will destroy insulin afterward. A method was devised for testing the relative efficacy of many solns. on a single day in the dog anesthetized with amytal. Such expts. with solns. introduced into a segment of the intestine prove that there is very rapid buffering of high or low pH. Both dogs and men exhibit great variability of response to this method of administering insulin. E. D. Walter

A comparative study of the effect of alkylresorcinols and related compounds upon the absorption of insulin from isolated intestinal loops of anesthetized dogs. Robert R. Sealock, John R. Murlin and Robert L. Driver. *Am. J. Physiol.* **128**, 92–6(1939); cf. preceding abstr.—The effect of the alkylresorcinols, ethyl-, propyl-, butyl-, pentyl-, hexyl-, heptyl-, and octyl-, on the absorption of insulin from isolated loops of the small intestine of anesthetized dogs has been compared. Of these compds. hexylresorcinol causes the greatest absorption of insulin as detd. by analysis of blood glucose. Evidence is presented to indicate that the hydrophylic-hydrophobic nature of hexylresorcinol is not the only factor involved in promoting insulin absorption. Other compds. of similar chem. nature were tested and found to be without effect under the conditions of the expt. E. D. Walter

Effects of an anterior pituitary growth preparation on metabolism in phlorizin diabetes. O. H. Gaebler and Walter J. Zimmerman. *Am. J. Physiol.* **128**, 111–20 (1939).—Bitches were given large injections of a growth prepn. on the 4th day of phlorizin administration. The calorigenic effect of the prepn. was superimposed on the high metabolism of phlorizin diabetes. In spite of this the wt. increased and the N output was less than in expts. with phlorizin alone. The effect of the prepn. on N output was increased by thyroidectomy. In meat-fed phlorizinized animals glucose and N output were diminished proportionately, leaving the D/N ratio unchanged; in thyroidectomized-depancreatized animals receiving a const. amt. of insulin the same doses of this pituitary prepn. were severely diabetogenic. The injected prepn. did not diminish N output by increasing the oxidation of fat, or of carbohydrate when latter was available. E. D. W.

Response of Brunner's glands to secretin. S. J. Fogelson and W. H. Bachrach. *Am. J. Physiol.* **128**, 121–3 (1939).—Intravenous injection of secretin is followed by the secretion of a viscid juice from the Brunner gland area of the duodenum, but proof is still lacking that secretion is entirely independent of the increased duodenal motility accompanying the secretion. E. D. Walter

Influence of massive doses of insulin on peripheral blood flow in man. David I. Abramson, Norman Schklowen, Meyer N. Margolis and I. Arthur Mirsky. *Am. J. Physiol.* **128**, 124–32(1939).—A study of the peripheral vascular responses to injections of massive doses of insulin in a series of patients with schizophrenia by means of the plethysmographic method. E. D. Walter

Certain therapeutically important triphenylmethane dyestuffs (Dominikiewicz) **10**. Group of organo-Hg compds., derivs. of allyl [pharmacotherapeutical properties] (Dominikiewicz, Kijewska) **10**. Cyclotetramethylenepyrazolone [therapeutical application] (Ruhkopf) **10**.

1—ZOÖLOGY

R. A. GORTNER

Respiration of fishes. I. Respiration of the Hungarian dogfish (Umbra lacustris Grossinger). Fritz Geyer and Hans Mann. *Zool. Anz.* **127**, 234–45(1939).—The O consumption of a normal dogfish was 18.5 g. O_2/kg. body wt./24 hrs. when the temp. of the water was 14–16°, but, if removal of the gases in the swimming bladder was prevented by keeping the fish under water in a closed tube for 24 hrs., the O consumption increased to 27.36 g.; immediately after the fish had swallowed air it was 19.2 g. If the swimming bladder was punctured or evacuated by reduction of the external pressure, the O consumption increased from 16.39 to an av. of 25.1 g. and from 19.2 to an av. of 33.55 g., resp. The O consumption of 4 fish kept in a closed tube for 26 hrs. was 3.89 g. O_2/kg. body wt./24 hrs.; after air-swallowing it fell to 3.09 g. The difference in O consumption calcd. per body wt. and for 24 hrs. between individual fish and a group of fish was due to a "group effect." The above figures are valid only for expts. with flowing water. The same ratio (2:1) of the O uptake of the gills (and skin) to that of the swimming bladder was also found in fish larvae of the same age. The swimming bladder in *U. lacustris* is, therefore, an accessory respiratory organ, the lack of which does not affect the ability of the fish to live. The gills, which normally take care of the greater part of the O requirement, are capable of meeting the total requirement. With a sufficiently high O content of the water the swimming bladder respiration is of minor importance. **II. Further contribution to the respiration of the Hungarian dogfish (Umbra lacustris Grossinger).** *Ibid.* 305–12.—The air respiration, water respiration and total respiration of this fish in g. O_2/kg. body wt./24 hrs. under different conditions were: in stagnant water, 16–18°, during the day, 33.40, 2.78, 36.18; in stagnant water during the night, 13.30, 3.89, 17.19; in O-poor stagnant water (O content of the water reduced from 9.57 mg. O_2/l. to 4.25 mg. O_2/l.), 35.70, 1.69, 37.39; in stagnant water with no possibility of air respiration, —, 4.54, —; in stagnant water with exclusion of the swimming bladder (evacuation), —, 27.45, 27.45 (?); in flowing water with the possibility of air respiration, — (not measurable in the exptl. period), 15.12, —, resp. These results confirm the earlier view that *U. lacustris*, by virtue of its swimming bladder which functions solely as an accessory respiratory organ, can live in waters with low O content, i. e., under unfavorable conditions. Ruth Berggren

The formation of dihydroxycholenic acid from apocholic acid in the toad. Tai Sihk Sihn. *Z. physiol. Chem.* **261**, 93–6(1939).—Feeding 22 g. of apocholic acid (I) to toads in doses of 0.2–0.3 g. daily caused the appearance of 0.065 g. of dihydroxycholenic acid (II) in their urine and 0.33 g. in their bile (142 animals). The double bond of I between 8 and 14 can be shifted to the 7-8 position in II in the organism as well as by ultraviolet light (*C. A.* **33** 2901[7]). Milton Levy

12—FOODS

H. A. LEPPER

Determination of tin in food products. A. G. Bosin and S. E. Spektor. *Voprosy Pitaniya* **7**, No. 2, 87–94(1938); *Khim. Referat. Zhur.* **2**, No. 1, 70(1939).—The method of Owe (cf. *C. A.* **17**, 3145) for the detn. of Sn in food prod-

ucts contains a no. of defects. In the process of mineralization (which requires a considerable length of time) a partial loss of Sn takes place. A dry method of ashing the sample is proposed, by which smaller samples can be used. The ash is treated with a 25% soln. of HCl, the Sn is reduced with Al, KI is added to the soln., and the soln. is titrated with $K_2Cr_2O_7$ in the presence of starch. The accuracy of the method reaches 95% of the theoretical. Another method for the detn. of Sn is also proposed which is based on the fact that the sulfide is treated with a standard I soln., excess of which is titrated with $Na_2S_2O_3$.
W. R. Henn

The use of nitric acid in ashing wheat, etc. B. S. Dmitriev. *Trudy Odesskogo Inst. Tekhnol. Zerna i Muki im. I. V. Stalina* **1938**, 89–93; *Khim. Referat. Zhur.* **2**, No. 2, 78(1939).—Detns. of nitrate and nitrite in ash showed that no appreciable error is caused by acceleration of the ashing by means of HNO_3. W. R. Henn

The influence of discharge rate of flours upon the concentration of the fatty materials of rice and its by-products. Roger F. Auriol and G. Huet. *Bull. mat. grasses inst. colonial Marseille* **23**, 209–13(1939).—With increase of the discharge rate (above 3.62%) of rice into flour, the percentage of fatty materials in the flour gradually decreases, as does also the percentage of fatty materials in the recovered pieces of rice grains. At a discharge rate of 9.5% and above, the percentage of fatty materials in the recovered pieces of rice grains remains approx. const. For discharge rates below 3.62% the flours had lower contents of fatty matter than were present at the figure mentioned, probably because of incomplete rupture of the aleuronic cells which are rich in fatty matter. George Ayers

Determination of corn meal in wheat flour. H. Radeloff. *Z. Untersuch. Lebensm.* **78**, 145–9(1939).—Stir a 5-g. flour sample with 10 cc. of chloral hydrate-HCl soln. (cf. Bredemann, *C. A.* **6**, 1325) until lump-free and boil (1½–2 min.) until clear. Add 10 cc. of chloral hydrate, which should dissolve the last traces of starch. Pipet 0.1-cc. portions of this to 4 slides (70 × 35 mm. with 40 × 24 mm. covers) from a pipet with a wide opening. The count is made on 5 cross strips on each slide. Work on known samples yielded a factor 7.6 which is the amt. of corn tissue protein networks per count per percentage of corn meal in the flour. The evaluation of unknown samples was based on data obtained on prepd. mixts. M. M. P.

Purification of wash waters in flour mills. V. Ya. Girshson. *Trudy Odesskogo Inst. Tekhnol. Zerna i Muki im. I. V. Stalina* **1938**, 119–30; *Khim. Referat. Zhur.* **2**, No. 2, 110(1939).—The wash waters can be successfully settled and purified in the first settling tank and filter. Since the wash waters have an alk. reaction, addn. of minute amts. of $CaOCl_2$ has an excellent chem.-bacteriol. disinfectant action. W. R. Henn

Determination of α- and β-amylases in flour. I. Glazunov. *Biokhimiya Khlebopecheniya* **1938**, No. 1, 51–9; *Khim. Referat. Zhur.* **2**, No. 3, 86(1939).—The method depends on the different thermolabilities of α- and β-amylases. The α-amylase is inactivated by heating for 15 min. on a water bath at 70°. Detn. of β-amylase by its dextrinizing power is less accurate than detn. by its sugar-forming properties. The activity of β-amylase depends to a great extent on the condition of starch. Starch with finer grains or with damaged grains forms sugar much faster than does the starch with coarse grains. A starch paste forms sugar 500–1000 times faster than the unprepd. starch. W. R. Henn

The role of α- and β-amylases in bread baking. E. G. Onishchenko. *Biokhimiya Khlebopecheniya* **1938**, No. 1, 39–50; *Khim. Referat. Zhur.* **2**, No. 3, 61(1939).—The action on the starch paste of α-amylase caused 23.1%, and of β-amylase 43.2%, sugar formation. From the action on dextrins of α-amylase were obtained 278 mg. and of β-amylase 370 mg. of maltose, and from the action on natural starch (not paste) 264 mg. and 42 mg. of maltose, resp. Addn. of α-amylase to the dough in the course of mixing caused an increased formation of dextrins and lowered the quality of the bread. The action of α-amylase can be inhibited by increase of the acidity of the medium. The action of β-amylase was mainly on the dextrins and it caused only a very slow formation of sugars from the unchanged starch grains. The addn. of this enzyme improved the quality of bread. W. R. Henn

The flavor of milk as affected by season, age and level of feeding dairy cows. J. C. Hening and A. C. Dahlberg. *J. Dairy Sci.* **22**, 883–8(1939).—The flavor of fresh milk and its keeping qualities as indicated by the percentage occurrence of oxidized flavor and the numerical score in aged milk were not influenced by the level of feeding under the conditions of the expt. The occurrence of oxidized flavor was considerably less in summer months but there was not a definite correlation between the exact period of feeding green cut legumes and the occurrence of oxidized flavors. The milk from first-calf heifers showed a higher incidence of oxidized flavors than milk from older cows, but the data were not considered sufficient to draw definite conclusions even for the one herd in which all the data for this study were obtained. A. H. Johnson

The effect of increased iodine feeding upon the iodine content of cow milk. Norman L. Mathews, Geo. M. Curtis and J. H. Meyer. *J. Dairy Research* **10**, 395–402(1939).—The milk and blood I of a herd of 30 Guernsey and 30 Holstein cows were detd. previous to and during the prolonged increased feeding of I to one-half of the herd. The increased amt. of I was fed as KI which was mixed uniformly with the grain feed. The blood I of the iodized cows was greatly and uniformly increased. The milk was increased, this increase being principally dependent on the amt. of I which was fed. During the late spring, the milk I from both the iodized and control cows was unusually low. During early autumn the milk I from the iodized cows was low. The milk from the iodized cows contained 7 to 26 times as much I as that from the control cows. An av. milk I of 80 γ % was obtained from the iodized cows through the mid-year period of 5 months. The data indicate that the I content of milk can be readily increased by increasing feeding of I. A. H. Johnson

Biochemical sugar determination. IV. F. Th. van Voorst. *Chem. Weekblad* **36**, 699–702(1939); cf. *C. A.* **33**, 6376².—By means of previously described methods directions are given for the detn. of the sugar content of milk powder, milk chocolate, cane-sugar sirup, cooking sirup, and household sirup and jam. V. *Ibid.* 715–16.—Directions are given for the detn. of sucrose, lactose, molasses or crude sugar in chocolate paste. F. S.

Bacterial growth in milk as a possible source of error in the phosphatase test. Harold W. Leahy, Leslie A. Sandholzer and Marian R. Woodside. *J. Bact.* **38**, 683(1939).—False pos. reactions may result from the hydrolysis of the bacterial nucleic acids. Tests should not be made on milks with microscopic counts above 8,000,000 per cc. or standard plate counts above 2,000,000 or interpreted with caution. John T. Myers

Skimmed condensed milk. K. E. Langwill. *Mfg. Confectioner* **19**, No. 12, 18–19(1939); cf. *Ibid.* No. 11, 24–5.—A discussion of the analyses of 3 com. samples with respect to candy manuf. George Ayers

Improvement in the viscosity of pasteurized cream through subsequent heat-treatment. Hilda F. Wiese, J. H. Nair and R. S. Fleming. *J. Dairy Sci.* **22**, 875–81(1939).—The process of increasing the viscosity of cream involving immediately warming the pasteurized cream to 86°F. in 20 to 25 min., vat cooling from 86°F. to 45°F. in 12 to 15 min., followed by surface cooling to 45°F. is termed the rebodying process. The fat phase of normal cream plays the most important role in the cream rebodying process. The fat membrane material of normal milk globules was found to be the most effective butterfat stabilizer for artificial cream and always resulted in a cream which would respond to the rebodying process. Stabilization of the butterfat with all or part of the constituents of normal skim milk did not yield artificial creams which would respond to rebodying. None of the emulsions prepd. from other than the normal fat globule membrane material responded to the rebodying expts. The constituents of the aq. phase of normal cream exert a beneficial effect on the rebodying process but this effect is not noted

except when the butterfat is stabilized by its normal membrane. The compn. of the butterfat appears to be a factor in the stability of cream subjected to the rebodying process. A. H. Johnson

Weight loss of stored margarine. A. Schloemer. *Z. Untersuch. Lebensm.* **78**, 138–41(1939).—Loss of 2% in wt. by evapn. of moisture occurred in 1 to 15 weeks in 1/4-kg. packaged com. margarines during storage. The wt. loss of the 1/2-kg. packages was slower. M. M. Piskur

Determination of insoluble substances in fruits and in berries. M. Kotlyarenko and A. Popel. *Spirto-Vodochnaya Prom.* **1938**, No. 10, 23–5; *Khim. Referat. Zhur.* 2, No. 2, 89–90(1939).—An extn. cylinder of glass, provided with a stopcock, is described. It is heated in a thermostat at 70–80°. Place a 25-g. sample in the cylinder in a preliminarily dried and weighed paper case, cover it with hot water. After every 20–30 min. change the water in the cylinder until the wash water gives no reaction for sugar with Fehling soln. Wash the cylinder 2–3 times with 96% alc., filling it for 20–30 min. Dry the paper case with the sample at 105° to const. wt. The detn. requires 15 hrs. W. R. Henn

Apple preservation with the aid of certain oils. Ia. Scupin. *Obst- u. Gemüseb.* **35**, 48–9(1939); *Rev. Applied Mycol.* **18**, 533.—Apples treated with 3 different oils at harvesting showed less incidence of *Gloeosporium album* after storage for 3, 4, 5 and 6 months in the case of 2 oils than controls but more in the case of the third oil. The third oil (No. 2243) caused injury to the fruit. O. E. S.

Factory and field application of maturity test for peas. S. L. Jodidi. *Canning Trade* **61**, 7–12(1939); cf. *C. A.* **34**, 186⁹.—J.'s maturity test which is based on the sp. gr. of peas and shows that peas of lower or higher sp. gr. indicate a better or poorer quality, resp., is characterized by the following properties: The test is accurate up to a few hundredths of one %, which is of special importance in sweet varieties of peas whose grades differ but very little. The test is rapid, requiring but 5 min. or less. It is free from waste, because the samples tested remain perfectly clean and can be added to the bulk of peas for canning or other processing. The whole app. costs only $25–50. S. L. Jodidi

Food value of artificially dried sweet lupine. W. Kirsch and H. Jantzon. *Biedermanns Zentr. B. Tierernähr.* **11**, 273–5 (1939).—Sweet lupine artificially dried in a rotary drier contains 11.82% digestible crude protein and 10.93% digestible pure protein. The digestibility of the protein is reduced by artificial drying. Felix Saunders

The chemist in the carbonated beverage industry. H. A. Showalter. *Can. Chem. Proc. Inds.* **24**, 621–2, 624 (1939).—The chemist is interested primarily in this industry in: (1) the cleaning of the bottles, (2) the control of the water supply and (3) the production of suitable carbonation. Control of these and tests on finished goods are discussed briefly. W. H. Boynton

Extermination of warehouse ticks. M. F. Ermolaev and A. E. Krivul'tsova. *Len i Konoplya* **1938**, No. 1, 23–7; *Khim. Referat. Zhur.* 2, No. 2, 100(1939).—Naphthalene, chalk, ordinary and the double superphosphates and talcum were tested for a rapid extermination of grain ticks. Naphthalene is recommended for wide use. The most effective dose was 500–1000 g. of naphthalene for each ton of the grain. W. R. Henn

Staff reports. Southern division. N. A. R. Pollock. *Queensland Dept. Agr. and Stock, Ann. Rept.* **1937–38**, 47–53.—Analyses are given of Sudan grass (young growth and in flower), chick pea (*Cicer arietinum*) (plant, seed and husk), several varieties of fodder grasses and 5 varieties of grain sorghums (plants and grain). Data on the digestible nutrients in the grain sorghums are also given. K. D. Jacob

Storing of carbohydrates by forage grasses. A. S. Morozov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 407–9(1939)(in English).—Investigations of *Bromus inermis* Leyss., *Lolium perenne*, *Festuca pratense*, and some other forage grasses, cleaned, killed, dried, and ground, gave the following results (figures given in tables): (1) Carbohydrates accumulate chiefly in roots, stems, shortened internodes and leaves. The carbohydrates stored are chiefly inulin-like substances and hemicellulose. (2) Sucrose always predominates over monosaccharides, its increase being attended by an increase in the total content of carbohydrates. (3) The carbohydrate content increases with the growth of the plant, attaining a max. at flowering. 4 references. A. H. Krappe

Roughage quality and quantity in the dairy ration, a review. C. F. Huffman. *J. Dairy Sci.* **22**, 889–980(1939). A. H. Johnson

Production of concentrated fodder and the cultivation of alfalfa. A. Demolon. *Compt. rend. acad. agr. France* **25**, 885–94(1939).—Alfalfa requires a high-Ca soil which assures a forage of high alkalescence. This is particularly valuable for dairies. Repeated addns. of large doses of $Ca(NO_3)_2$ for alfalfa cultivation on a loam soil result in a significant decrease in the N content of the crop. A general discussion of the raising of alfalfa is given. J. R. A.

The drying of sugar beets, leaves, and tops as well as albuminous green fodder. H. Claassen. *Centr. Zuckerind.* **47**, 801–2(1939).—After drum drying the crude protein content of sugar-beet chips was 10–11%; of agriculture waste, 16.5–19.8%; alfalfa, 19.9–21.3%; red clover, 18.8–19.5%; vetch mixt., 24.1–24.8% and pure vetch, 29.1%. High digestibility was claimed for sugar-beet fodder. W. W. Binkley

Food value of artificially dried beet tops as fodder for milk cows and work horses. Robert Ehinger. *Biedermanns Zentr. B. Tierernähr.* **11**, 389–427(1939).—The coeff. of digestibility of dried beet leaves was lower than that for the fresh leaves. Both dairy cattle and work horses eat dried beet leaves readily up to 6 kg. The fodder has no harmful effects on either animals. Felix Saunders

Feeding whole oats to work horses. Gerhard Winkler. *Biedermanns Zentr. B. Tierernähr.* **11**, 428–34(1939).—Work horses use whole and rolled oats equally well. Felix Saunders

---

Variations in the cooking quality of potatoes as influenced by fertilizers (Blood, Haddock) **15**. Report of the agricultural chemist [on pasture grasses, roughage, etc.] (Gurney) **15**. Extruded tubing of nitrocellulose compn. [for sausage casings] (U. S. pat. 2,175,313) **23**.

Bleaching flour and the like. Souren Z. Avedikian. U. S. 2,175,172, Oct. 10. Bleaching is effected by use of an addn. compd. of SO_2 with a nitrite such as that of Na, Li, K or Ca in very small proportion, which also improves the water-absorption value of the flour and the texture of bread made from it.

Inhibiting oxidative deterioration of compositions containing glyceride oils and fats, etc. Sidney Musher (to Musher Foundation Inc.). U. S. 2,176,022, Oct. 10. Food emulsions contg. oils and fats, etc., are stabilized against oxidative deterioration by adding to them a small proportion of an unbleached cereal flour such as that of oats, degerminated maize or barley. U. S. 2,176,023 relates to stabilizing products such as cream, butter and ice cream by adding less than 2% of a similar material. U. S. 2,176,024 relates to the similar use of a finely divided deoiled seed residue such as deoiled soybean flour.

Stabilizing foods, etc., against oxidative deterioration. Sidney Musher (to Musher Foundation Inc.). U. S. 2,176,026, Oct. 10. An aq. or alc. ext. such as one of unbleached oat or corn flour is added in small proportion to products such as mayonnaise, liquid egg white, biscuits or coffee. U. S. 2,176,027, relates to the similar stabilization of water-contg. food compns. such as cream, concd. orange juice, cream cheese, ice cream or salad dressings. U. S. 2,176,028 relates to similar stabilization of meat and fishery products. U. S. 2,176,029 relates to stabilization of foods with an alc. extract of a cereal flour which before extn. contains less than 5% total phospholipins. U. S. 2,176,030 relates to stabilization of glyceride oils and foods contg. them by use of an alc. extract such as one of deoiled peanut press cake or deoiled soybean flour. U. S.

2,176,031 relates to a like use of a finely divided defatted cacao residue or its alc. ext.

Stabilizing water-containing foods such as milk and cream against oxidative deterioration. Sidney Musher (to Musher Foundation Inc.). U. S. 2,176,033, Oct. 10. A small proportion of crude cane sugar or crude beet sugar is added as a stabilizing agent. U. S. 2,176,034 relates to the conjoint use of a sugar and water-sol. antioxygens such as those extd. from unbleached corn. U. S. 2,176,035 relates to the use together of a sugar and water-sol. antioxygens such as those of deoiled soybean flour. U. S. 2,176,036 relates to the use together of salt and antioxygens such as those extd. from corn. U. S. 2,176,037 relates to the use together of cereal or seed materials such as oat flour and an aq. or alc. ext. such as that of unbleached whole oat flour, for stabilizing various foods.

Apparatus for measuring the curd tension of milk. Laurence Batchelder (to Submarine Signal Co.). U. S. 2,175,173, Oct. 10. App. used includes a curd-penetrating knife, a supporting frame for the knife, a container for holding Hg on which the frame may float, and a scale and indicator for indicating the surface level of Hg with respect to the float. Various other structural and operative details are described.

Centrifugal separator suitable for separation of cream from milk. Hans O. Lindgren (to De Laval Separator Co.). U. S. 2,174,272, Sept. 26. Various details of structure and operation for discharge regulation.

Stabilizing desiccated milk products. Faw Y. Chuck. U. S. 2,174,734, Oct. 3. A process for producing a dry stable milk product from a source material contg. sufficient α- and β-lactose anhydrides as to render the material markedly hygroscopic involves dehydrating the source material to remove therefrom all but about 10% of the water therein and so the partially dehydrated material is powdery, agitating the partially dehydrated material at a temp. below 93.5° for a time sufficient to hydrate any hygroscopic components in the material and to stabilize the partially dehydrated material, and finally removing substantially any moisture in excess of that present as water of hydration of constituents of the stabilized material.

Frozen foods such as fish. Robert H. Bedford. U. S. 2,175,680, Oct. 10. Foods such as fish are provided with a transparent noncracking ice glaze formed from an aq. soln. of a polyhydric alc., ketonic alc. or aldehydic alc. such as glycerol, ethylene glycol, arabinose, glucose, mannose, galactose, fructose, sucrose or maltose, preferably brought to a pH of about 5.5, as by use of HCl.

Hydrogenated vegetable-oil shortening. Truman M. Godfrey and Victor Serbell (to Lever Bros. Co.). U. S. 2,174,364, Sept. 26. App. is described, and a method of finishing substantially dry hydrogenated vegetable-oil plastic shortening in which the oleaginous material comprising the same in a liquid state is converted into a semi-solid plastic condition, involving simultaneously agitating and chilling the material uniformly and rapidly to crystallize at least a portion of it; terminating the agitating and chilling operation and withdrawing the oleaginous material in a crystd. creamy viscous condition such as would be capable of retaining air and when the resultant latent heat of crystn. available is such as to impart to the oleaginous material a temp. approx. 25° to 30°, and agitating the material in creamy viscous condition while it acquires the tempering temp. before packaging when the resultant latent heat of crystn. available is at least sufficient to impart to the oleaginous material a temp. approximating a predetd. tempering temp.; withdrawing the oleaginous material in a crystd. creamy viscous condition capable of retaining air; and permitting the material to acquire such predetd. tempering temp.

Blended shortenings. Arne Gudheim (to Lever Bros. Co). U. S. 2,174,365, Sept. 26. A plastic shortening which may carry an inert gas or air, of uniform appearance and texture, comprises a base of partially hydrogenated vegetable oil that is semisolid but somewhat softer than desired at room temp., with which is mixed 0.5 to 5% of a hard fat having a titer of not less than 65°, the hard fat being prepd. by hydrogenating a vegetable oil which, when completely hydrogenated, has a titer of not less than 65°, whereby the mixt. has a plasticity at room temp. suiting it for culinary operations, and retains its plasticity over a wide temp. range. Various examples with details are given.

Cooking salt mixture. Frederick C. E. Harry and Henry H. York (to Chemtex Ltd.). U. S. 2,175,955, Oct. 10. See Brit. 507,904 (*C. A.* **34**, 542[8]).

Apparatus for expressing and separating juices and rind oils from citrus fruits. Frederick L. McCulloch. U. S. 2,174,909, Oct. 3. Various structural, mech. and operative details.

Retarding deterioration of hides, fish, meat, fruits, vegetables, etc. Sidney Musher (to Musher Foundation Inc.). U. S. 2,176,025, Oct. 10. The materials are treated with a saline soln. and with a cereal flour such as that of maize, oats, wheat, rye or barley. Various examples with details are given.

Containers such as metal cans for holding foods or beverages. William C. Rainer (to Crown Cork & Seal Co.). U. S. 2,175,972, Oct. 10. A metal container is provided with a relatively thin layer of shellac on its inner surface with a thicker layer of wax such as paraffin wax on the shellac coating, the shellac being in sufficient amount to overcome the surface tension differential and congealing force of the wax and to enhance its elasticity during solidification and thereby avoid fractures of the wax coating at the seam and mouth portions of the container.

13—CHEMICAL INDUSTRY AND MISCELLANEOUS INDUSTRIAL PRODUCTS

(PLASTICS, RESINOIDS, INSULATORS, ADHESIVES, ETC.)

HERMAN A. BRUSON

The technical industries of Rhode Island. Willard L. Morgan. *Trans. Am. Inst. Chem. Engrs.* **35**, 779–87 (1939).—The industries of R. I. produce mainly consumer goods and are characterized by wide variety and by the use of highly skilled labor. They originate from the capital derived during the early sailing days and from the application of machinery and water power in the development of the cotton industry which was started in the U. S. in this section. Textile industries are today the dominant activity, with jewelry and machinery following. Chemicals have been subordinant to these industries. The only heavy chem. industry is the Rumford Chemical Co. The manuf. of alkalies in the U. S. was largely brought about by R. I. interests. A review of the labor shows it to be essentially native whites. C. L. Mantell

A new development for promoting the physical-chemical control of technical operations. P. Wulff. *Chem. Fabrik* **1939**, 494–5; cf. *C. A.* **33**, 7621[7].—An outline of the duties and aims of the "Research and Consulting Office for phys.-chem. factory control and laboratory technic." J. H. Moore

The poisonous war gases. Johs. C. Bock. *Arch. Pharm. Chem.* **46**, 567–88(1939). Otto Johnson

Radium poisoning: A review of present knowledge in relation to war risks. J. Read. *Brit. J. Radiol.* **12**, 632–7(1939).—The possibility is considered of a bomb destroying a Ra container and scattering the element, and of persons subsequently ingesting or inhaling lethal doses. The literature on Ra poisoning and on inhalation of dust is reviewed; no new material is presented. Bibliography. E. H. Quimby

Physicochemical properties of poisonous substances used in warfare. G. Gavrilov. *Khimiya i Oborona* **1938**, No. 6, 11–13; *Khim. Referat. Zhur.* **2**, No. 1, 113(1939).—

The following phys. properties of the poisonous substances are described: vapor pressure, volatility, d. of vapors, adsorption by activated charcoal, color, odor, soly., and b. p., together with their significance for war use and for defense from poisonous substances. Chem. stability under storage conditions and in use, ease and velocity of hydrolysis, oxidation by O of the air, reactivity with the usual degasifiers, and the detection and the distinguishing of the poisonous are discussed. W. R. Henn

Chronic exposure to benzene. I. The industrial aspects. Manfred Bowditch and Hervey B. Elkins. *J. Ind. Hyg. Toxicol.* **21**, 321-30 (1939).—The commonly accepted max. allowable concn. for benzene vapor is 100 p. p. m. Also 50% is proposed as the limiting safe urine/sulfate ratio. Based on plant studies, these 2 standards are not correlative. Benzene vapor concn. of 75 p. p. m. is proposed as the max. **II. The clinical effects.** Francis T. Hunter. *J. Ind. Hyg. Toxicol.* **21**, 331-54 (1939).—Eighty-nine individuals exposed to benzene fumes were observed and studied. Ten cases were fatal. Benzene poisoning may produce polycythemia or anemia; leucocytosis or leucopenia; leucemia; eosinophilia, megalocytosis or microcytosis; the presence of immature marrow elements in an otherwise normal blood. Complete blood pictures should be used in the diagnosis of benzene poisoning. Acclimatization to C_6H_6 fumes does not occur. **III. The pathologic results.** Tracy B. Mallory, Edward A. Gall and Wm. J. Brickley. *J. Ind. Hyg. Toxicol.* **21**, 355-94 (1939).—Histologic material from 19 patients (14 autopsies and 5 biopsies) is described. Not merely bone marrow but the entire hematopoietic system characteristically shows changes. Hyperplastic reactions are more common in the male, hypoplastic in the female. A. L. Elder

The hematological effects of benzene poisoning. Lowell A. Erf and C. P. Rhoads. *J. Ind. Hyg. Toxicol.* **21**, 421-34 (1939).—Hematological findings on 9 patients with C_6H_6 poisoning are reported. The increased rate of destruction of erythrocytes may be one cause of anemia of benzene poisoning. A. L. Elder

Benzene poisoning in the rotogravure printing industry in New York City. Leonard Greenburg, May R. Mayers, Leonard Goldwater and Adelaide R. Smith. *J. Ind. Hyg. Toxicol.* **21**, 395-420 (1939).—Benzene poisoning in 3 fast-press rotogravure printing plants in New York City is reported. Concns. of C_6H_6 vapor varied from 11 to 1060 p. p. m. Several cases of poisoning occurred where the concn. was less than 100 p. p. m. The use of C_6H_6 was discontinued in these plants. All men originally exposed are being examd. periodically. Blood studies and urine sulfate detns. are reported. A. L. Elder

The acute and subacute toxicity of morpholine. Thomas F. Shea, Jr. *J. Ind. Hyg. Toxicol.* **21**, 236-45 (1939).—Morpholine is used with fatty acids as an emulsifying agent for polishes, etc. When fed undild., it is a deadly poison. The m. l. d. of dild. morpholine for albino rats is 1.6 g. per kg. Application to the skin damages the secreting tubules of the kidneys. Lung damage is similar to that of ammonia. A concn. of 12,000 p. p. m. in the air is barely tolerable to human subjects. Neutralized morpholine when absorbed through the skin causes no toxic symptoms. Numerous animal expts. are reported. A. L. Elder

Tissue reaction to some carbon arc dusts. E. L. MacQuiddy, J. Perry Tollman, Leroy W. La Towsky and Stanley Schonberger. *J. Ind. Hyg. Toxicol.* **21**, 498-513 (1939).—Some high-intensity carbon arc ashes appear to cause mildly proliferative reactions when injected intraperitoneally in the albino rat. Arc dusts administered by intratracheal and subcutaneous routes in rabbits are relatively inert. The rare earth metal salts, some of the carbon arc ashes, $Ca_3(PO_4)_2$, CuO and CaF_2 appear to be essentially inert. A. L. Elder

Acute poisoning in animals after intraperitoneal and intratracheal administration of dusts. J. Perry Tollman, E. L. MacQuiddy and Leroy W. La Towsky. *J. Ind. Hyg. Toxicol.* **21**, 514-16 (1939).—Injection of certain dusts caused acute death which was due to sol. cupric ion. Intraperitoneal injection of 2.5 mg. of $CuSO_4$ into rats caused death in 1-3 hrs. A. L. Elder

Volatilization of lead below 800°. Paul F. Rezin and Philip Drinker. *J. Ind. Hyg. Toxicol.* **21**, 461-3 (1939).—Significant amts. of Pb are carried off from molten baths. A. L. Elder

Removal of chloropicrin from railroad cars after disinfection. V. I. Efimenko. *Higiena i Sanitariya* **1938**, No. 2, 77-9; *Khim. Referat. Zhur.* **2**, No. 1, 114 (1939).—The method is based on the ability of chloropicrin in alc. to give with sulfates salts of nitromethanedisulfonic acid. It is recommended to burn S (1.5-2 kg./car) and to atomize after 1.5 hrs. denaturated alc. (3-3.5 l./car). The entire treatment takes 36-48 hrs. W. R. Henn

Synthetic resin cements. A. Foulon. *Nitrocellulose* **10**, 205-6 (1939).—A review. E. M. Symmes

The hardening of phenol-formaldehyde resins. II. Franz Hanus, Erich Fuchs and Erich Ziegler. *J. prakt. Chem.* **153**, 327-36 (1939); cf. *C. A.* **33**, 5378[8].—Further evidence establishes the formation of ether bridges as a primary reaction in the resinification of dimethylolphenols. The following were prepd. from CH_2O, NaOH and the corresponding *p*-substituted phenol: *4-ethyl-2,6-dimethylolphenol* (I), m. 85.8-86.6°, *2,6-dimethylol-4-propylphenol*, m. 85.4-85.8°, *4-butyl-2,6-dimethylolphenol* (II), m. 67.0-67.4°, *4-tert-butyl-2,6-dimethylolphenol dialcohol* (III), m. 74-5°. On heating all these lose about 1 mol. H_2O and 0.37-0.5 mol. CH_2O at 100-200°. The temp. at which CH_2O evolution begins is higher the greater the size of the substituent, and is also higher for II than III. The *p-ClH$_3$C$_6$H$_3$SO$_3$H ester* of I m. 130-1° and loses 1 mol. H_2O at 150-90° but practically no CH_2O; the corresponding ester of 4-cyclohexyl-2,6-dimethylolphenol behaves similarly. The *p-ClH$_3$C$_6$H$_3$SO$_3$H ester* of III (impure) m. 140°. A 35% yield of *1-hydroxy-2,6-bis(bromomethyl)-4-cyclohexyl-benzene* (IV), m. 81.8°, is obtained from HBr and the resin formed by the loss of 1 mol. H_2O from 4-cyclohexyl-2,6-dimethylolphenol at 140°; IV is also formed directly from HBr and the dialcohol. The *dibromide* of *2,6-bis(bromomethyl)-p-tolyl p-toluenesulfonate*, m. 122.3-122.5, is obtained either from *p*-cresol dialcohol *p*-toluenesulfonate or from its resinification product formed by loss of 1 mol. H_2O at 204°, by treatment with HBr. A. F. S.

Study of the electric insulating properties of paper boards by the method of rapid aging. Yu. V. Koritskiĭ, A. A. Volkova and B. V. Kossovich. *Bumashnaya Prom.* **17**, No. 8, 27-33 (1939).—Paper boards and condenser paper were subjected to rapid aging in Russian transformer oil and in imported acid-refined mineral oil at 150°. The η and mech. properties were detd. after aging and the results are given in tables and graphs. The boards aged more intensively in oil than in air. The sulfate specimens were most resistant against heat in the oil. B. Z. Kamich

Preparation of adhesives from raw materials obtained in U. S. S. R. V. N. Tsvetkov. *Legkaya Prom.* **1938**, No. 5, 99-109; *Khim. Referat. Zhur.* **2**, No. 1, 105 (1939).—A no. of formulas for new adhesives and for their utilization are given. Addn. to synthetic rubber of 75-200% (of the dry residue) of rosin gives best results. Gas black and MgO give best results as active fillers. Benzene was used as solvent for adhesives from synthetic rubber. Formulas for adhesives prepd. from gutta-percha with rosin are given. Butyl and ethyl acetates were used as solvents instead of the toxic benzene and dichloroethane. W. R. Henn

Importance of chemistry in pest control. R. C. Roark. *Pests* **7**, No. 11, 14-17 (1939).—A review discussing the chemistry of pyrethrum, derris, cube, timbo, F compds., borax, As compds., $TlSO_4$, P compds., tartar emetic, petroleum oils and fumigants. Henry H. Richardson

Unusual pest problems. J. J. Davis. *Pests* **7**, No. 12, 15 (1939).—$Ca(CN)_2$ dust is recommended to eradicate *bees*, *hornets* and *wasps* around and in buildings or carp grounds. Henry H. Richardson

Interesting household pest control problems. P. N. Annand. *Pests* **7**, No. 12, 6-7 (1939).—The problems involved with fumigants, termite-control chemicals and

chemicals used to control insects attacking fabrics, foods and man are discussed. Henry H. Richardson

Test methods for recording moribund kill (given by household sprays). H. E. Whitmire. *Soap* (*Sanitary Products Sect.*) **15**, No. 11, 99, 101, 103, 123 (1939).—The addn. of rotenone and related compds. to household sprays increased the no. of moribund flies present 24 hrs. after spraying because of the slower toxic action of these compds. (*C. A.* **28**, 2837[9]). W. suggests that after flies have been sprayed by the Peet Grady method (*C. A.* 22, 4734) they be placed in an open-top screen cage placed inside another large cage so that dead, moribund and active flies can be more easily sepd. H. H. Richardson

Construction and use of an olfactometer for muscoid flies, and a discussion of interpreting results. Craig Eagleson. *Soap* (*Sanitary Products Sect.*) **15**, No. 12, 123, 125, 127 (1939).—A U-shaped metal tube 15 cm. in diam. is used in testing the attractant or repellant qualities of different chemicals to the house fly *Musca domestica*, stable fly *Stomoxys calcitrans* and screw worm fly *Cochliomyia americana*. The flies are placed in the tube one arm of which is perfused with the vapor of the chemical tested. At regular intervals counts are made of the no. of flies located on the screen at the end of the arms of the U. A formula is given for calcg. the efficiency of the different chemicals. Two references. Henry H. Richardson

The control of rats and mice. Donald A. Spencer. *Pests* **7**, No. 12, 8–9 (1939).—A substitute is needed for Tl because of its high cost and low supply. As_2O_3 ground to particles of 3–5 microns was about 5 times as toxic as standard-size As_2O_3 (passing 100-mesh sieve). Finer grinding of Zn_3P_2 also increases efficiency. High temps. generated in grinding *red squill* will detoxify the powder. Many so-called attractant chemicals used in com. baits are ineffective. Moist baits and fresh foods are usually more effective than dry baits and preserved foods. Henry H. Richardson

---

Canister for gas masks. Augustin M. Prentiss. U. S. 2,174,528, Oct. 3. Various structural details.

Oxygen distributor for use with face masks. Frank G. Manson. U. S. 2,174,523, Oct. 3. Various details of an app. with baffles for deflecting O as desired.

Forming articles such as cups, jars or bottles from organic plastic material such as cellulose derivative and synthetic resin compositions. Enoch T. Ferngren (to Plax Corp.). U. S. 2,175,053, Oct. 3. Various details of app. and operation. U. S. 2,175,054 (Enoch T. Ferngren and Wm. H. Kopitke, joint inventors; to same assignee) relates to an app. suitable for forming hollowware from org. plastic material.

Thermoplastic molding powder. Robert V. Townend and Weaver R. Clayton (to Wm. Zinsser & Co.). U. S. 2,175,232, Oct. 10. A molding powder is formed of shellac, ZnO and CaO, MgO or Pb oxide.

Molding thermoplastic materials. Hans Gastrow (to Franz Braun A.-G.). U. S. 2,174,311, Sept. 26. App. is described, and a method suitable for the manuf. of molded articles from materials such as cellulose acetate or polyvinyl compds. which comprises introducing the thermoplastic material to be molded in granular form into a preheating chamber, preheating the material at a temp. lower than that required to produce fusion thereof, the while agitating the same and discharging the granular preheated material into a molding cylinder.

Polyvinyl halide compositions suitable for hot molding. Claude H. Alexander (to B. F. Goodrich Co.). U. S. 2,174,545, Oct. 3. For stabilizing gamma polyvinyl chloride, water glass is incorporated with it on a hot mill, followed by milling until the water has evapd.

Synthetic resins. Israel Rosenblum. U. S. 2,175,215, Oct. 10. An oil-sol. resin suitable for use in coating compns. is produced by treating materials such as amyl phenol about 100 with phenol 100, 100% formaldehyde 94 and the monoglyceride of a drying oil such as that of linseed oil 200 parts (suitably with heating to 150° until an oil-sol. condensate is obtained).

Phenolic-formaldehyde resins. Winfrid Hentrich and Fritz Schlegel (to Henkel & Cie. G. m. b. H.). U. S. 2,175,393, Oct. 10. Condensation products which are suitable for coatings or for molding are produced by condensing a phenol, an olefin such as α-butylene and CH_2O or its polymers, with use of perchloric acid (suitably at 80°).

Resinous products from lactic acid. Paul D. Watson (to the people for free use). U. S. 2,174,491, Sept. 26. A resinous product suitable for use in coating wood, metals, etc., is obtained by a process which involves heating aq. lactic acid in contact with a high-boiling petroleum fraction ranging from 155° to 216°, while distg. off the free and combined water; continuously returning the distd. entraining liquid to the mixt.; sepg. the resulting product from the entraining liquid; adding furfural, glycerol and ethyl alc. thereto, and subjecting the resulting product in substantially thin layers to temps. ranging from 150° to 170° for a period of 2–6 weeks.

Urea-formaldehyde reaction product suitable for casting and molding. Leonard Smidth. U. S. 2,174,535, Oct. 3. A process of producing urea-CH_2O condensation products suitable for casting and molding comprises mixing CH_2O and urea in a molar ratio of 2 to 1.1–1.33, causing the mixt. to react under conditions of a pH value above about 5 which form a cloudy soln., continuing the reaction until the viscosity of the reacting soln. has increased to an extent indicated by an increase in the time of flow of a few sec. from a described standard pipet which period in any case is insufficient to form a clear soln. having hydrophobic properties, then evapg. off the water present under acidity, temp. and time conditions which do not appreciably advance the reaction, until a sample of the material will form a ball in cold water.

Phenolic condensation products. Ludwig Cserny (to Resinous Products & Chemical Co.). U. S. 2,175,793, Oct. 10. A process of producing glass-clear, transparent, light-resistant condenstion products involves condensing a phenol with 1–3 mol. equivs. of CH_2O in the presence of an alkali, acidifying with lactic acid, adding a reactive urea-CH_2O condensation product, and heating to harden completely the mixt.

Stable solutions of urea-formaldehyde condensation products. Oskar R. Ludwig (to Resinous Products & Chemical Co.). U. S. 2,175,475, Oct. 10. A process of prepg. a stable aq. soln. of a urea-CH_2O intermediate condensation product involves heating a neutral aq. soln. of urea and CH_2O in the presence of an amt. of an alk. earth metal chloride chemically equiv. to 3–25% of $CaCl_2$ based on the wt. of urea, until amorphous products of relatively low mol. wt. are formed, and then cooling the mixt. to stop the reaction.

Heat insulation. Wm. S. Wilson (to Monsanto Chemical Co.). U. S. 2,174,770, Oct. 3. Finely divided Si or ferro-Si is used with materials such as silica aerogel.

Electrical insulating compositions suitable for use in transformers, etc. Arthur A. Levine and Oliver W. Cass (to E. I. du Pont de Nemours & Co.). U. S. 2,174,289, Sept. 26. A nuclear chlorinated ethylbenzene contg. 3 to 5 Cl atoms per mol. is used with a nuclear chlorinated isopropylbenzene contg. 4.0 to 4.5 atoms of Cl per mol., which serves as a freeze-point depressant. Cf. *C. A.* **33**, 2254[1].

Composite insulating slabs. Paul S. Denning (to F. E. Schundler & Co.). U. S. 2,175,715, Oct. 10. App. is described, and a method of making an insulating slab from granules of exfoliated vermiculite fiber, and cement wherein the quantity of vermiculite is substantially greater than the quantity of cement, which method is characterized by suspending granules of exfoliated vermiculite together with thin plates or laminae of vermiculite in a cementitious slurry in which the vermiculite is buoyant, the slurry contg. a small percentage of fiber, placing the mixt. in a mold having a perforated bottom, applying suction to draw out the liquid constituent of the slurry, the fiber holding the vermiculite in slightly sepd. condition to facilitate withdrawal of the liquid, the liquid being withdrawn without substantially compressing the vermiculite so as to leave the latter free to arrange its particles with their flat faces generally parallel to the bottom.

Insulating fluids such as oil in pipes around insulated electric cables. Charles E. Bennett (to Okonite-Callender Cable Co.). U. S. 2,174,961, Oct. 3. Various details of app. for automatic pressure regulation.

Apparatus for testing the insulating properties of assembled spark plugs with porcelain insulation. Cleveland C. Soper (to Firestone Tire & Rubber Co.). U. S. 2,175,038, Oct. 3. Various structural, elec. and operative details.

Coating rubber-insulated wires or the like. Charles W. Abbott. U. S. 2,175,099, Oct. 3. App. is described, and a method for continuously applying to a rubber element, like the rubber covering of a conductor, a viscous coating material having volatile constituent and effecting an intimate bond therebetween which involves continuously extruding vulcanizable rubber compn. onto a longitudinally moving conductor, feeding the conductor with the compn. thereon throughout a continuous vulcanizer chamber provided with a suitable heating medium substantially to vulcanize the rubber compn. and to impart to the conductor and its covering a heat content at substantially the temp. of vulcanization, applying to the surface of the rubber covering as it continues to move and while still in heated condition a coating material the volatile constituent of which is substantially instantaneously volatilized by the heat content of the rubber element, withdrawing heat from the rubber covering and conductor prior to applying the coating material to suit the heat content of the rubber covering and conductor to the evapn. characteristic of the volatile constituent of the coating material and thereby detg. the rate of setting of the coating material, and reeling up the rubber-covered conductor with the set coating on the rubber.

Copper wire coated with vinyl resin. Raymond H. Thielking (to Schenectady Varnish Co.). U. S. 2,174,912, Oct. 3. A Cu wire suitable for elec. coils, etc., is provided with a smooth, continuous, flexible, adherent coating comprising the conjoint polymerization product of vinyl chloride and vinyl acetate polymerization to a mol. wt. above 10,000.

Polymerized nitriles. Anderson W. Ralston (to Armour and Co.). U. S. 2,175,092, Oct. 3. See Can. 382,579 (*C. A.* **33**, 8627[7]).

γ-Polyvinyl chloride. Claude H. Alexander (to B. F. Goodrich Co.). U. S. 2,175,049, Oct. 3. A mixt. of this compd., suitable for use as a *dielectric*, is prepd. by incorporating it with PbO and a thianthrene such as 2,6-dimethylthianthrene.

Dielectric benzotrifluoride compositions suitable for use in transformers, etc. Lee C. Holt and Herbert W. Daudt (to Kinetic Chemicals, Inc.). U. S. 2,174,512, Oct. 3. Use is made, alone or in mixts., of compds., such as tetrachlorobenzotrifluoride (which may be made by chlorinating benzotrifluoride and which b. about 247–9°, freezes at about 10°, and has a viscosity of about 35 sec. at 37.8° and a dielec. const. at 25° of about 4.5). U. S. 2,174,513 relates to products obtained by chlorinating benzotrifluoride, with production of a dichlorobenzotrifluoride b 178–180° alone or mixed with related compds. and having dielec. properties. Several examples with details are given.

Waterproof adhesives suitable for general use. Edwin O. Groskopf (to Patent and Licensing Corp.). U. S. 2,175,797, Oct. 10. A substantially odorless, uniformly sprayable and brushable adhesive comprises an aq. emulsion contg. approx. 40–45% of an adhesive thermoplastic material, approx. 0.8 to 1.2% of soap as the emulsifying agent for the thermoplastic material, approx. 1.3% of clay whereby to inhibit flow under heat of a dried film deposited from the compn. without impairing the rapid setting properties of the wet film, and approx. 6 to 9% of rubber in dispersed form whereby to impart elasticity and increased bonding strength to the dried film of the compn., said thermoplastic material consisting of approx. equal parts by wt. of asphalt not readily miscible with rubber and a material selected from the group consisting of cumar resin, albino asphalt and asphalts low in asphaltenes whereby to render the first-named asphalt component of the thermoplastic material miscible with said rubber.

Adhesives and sizings from seed meals such as peanut or soy bean meal. John F. Corwin and Henry V. Dunham. U. S. 2,174,438, Sept. 26. A readily dispersible adhesive base is prepd. by dissolving matter from a seed meal in an alk. soln. such as one of NH_3 or borax, sepg. insol. matter from the soln., and evapg. the soln. to substantial dryness.

Thermoadhesive compositions suitable for use on paper tapes, etc. Ernest L. Kallander (to Dennison Mfg. Co.). U. S. 2,174,885, Oct. 3. Thermoadhesive compns. comprise a polyvinyl resin having a softening point of about 65°, shellac having a softening point of about 70° and a fluxing resin having a softening point falling within a range of about 32–54°, the polyvinyl resin, shellac, and fluxing resin all being compatible and being present in the compn. in approx. the proportions of 60, 20, and 20, resp., to impart to the compn. a softening point of about 57°, and the fluxing resin being prepd. by condensing derivs. of the terpene series with polycarboxylic acid and esterifying with polyhydric alc. Cf. *C. A.* **33**, 3926[1].

Sound-deadening adhesive suitable for use with pads of vehicle bodies. Joseph A. Torri (to J. W. Mortell Co.). U. S. 2,175,767, Oct. 10. A noninflammable, sound-deadening adhesive, adapted to secure pads to sheet metal, contains Na silicate approx. 60, emulsified asphalt 12 and an inert filler such as clay 28 parts.

Solid solution of acetates of sugars. Victor Walthausen and Lylla R. Metry. U. S. 2,174,541, Oct. 3. By acetylating a partially dried invert sugar sirup, an *adhesive* is produced comprising a solid soln. contg. sucrose octa-acetate 20–80 and invert sugar penta-acetates 80–20 parts. Such an adhesive does not readily discolor and is relatively nonbrittle.

Wetting agents, etc. Alfred W. Baldwin, Henry A. Piggott, Francis S. Statham and Imperial Chemical Industries Ltd. Brit. 508,477, June 28, 1939. Sulfonated derivs. of amidomethyl compds. having the formula $RCONHCH_2R'OR''$, where R is an aliphatic radical having at least 8 C atoms, R′ is a radical of the C_6H_3 or $C_{10}H_3$ series and R″ is H or a radical of the aliphatic, aliphatic-aromatic or aromatic series, are prepd. by (1) direct sulfonation of the parent amidomethyl compd., (2) reaction of a sulfonated phenol or phenol ether with CH_2O and an amide of formula $RCONH_2$ or with the methylol deriv. of such an amide, or (3) reaction of a phenol or phenol ether, simultaneously with a sulfonating agent and a methylol compd. of an amide of formula $RCONH_2$ or a mixt. of such an amide with CH_2O. Among examples, (1) stearohydroxybenzylamide, prepd. by condensing stearohydroxymethylamide (I) with PhOH by means of $ZnCl_2$, is sulfonated with $H_2SO_4.H_2O$, (2) laurohydroxymethylamide is condensed with Na 2-naphthol-3,6-disulfonate by means of $ZnCl_2$ in glacial AcOH, and (3) I is condensed and sulfonated with anisole.

Menthane derivatives. Joseph L. Richmond (to E. I. du Pont de Nemours & Co.). U. S. 2,174,505, Sept. 26. By treatment of menthane with a gaseous mixt. of SO_2 and Cl (suitably at 30–80° with exposure to actinic light), compds. are obtained such as menthanedisulfonyl chloride, *useful as wetting agents* and for other purposes.

Treating liquid alkanes with sulfur dioxide and chlorine. John M. Tinker and Arthur L. Fox (to E. I. du Pont de Nemours & Co.). U. S. 2,174,507, Sept. 26. A liquid alkane contg. 5 to 12 C atoms (such as C_6H_{14} or C_7H_{16} for the production of *mercerizing assistants*) is treated with admixed gaseous SO_2 and Cl at a temp. below the decompn. point of the formed hydrocarbon sulfonyl chlorides. U. S. 2,174,508 (Arthur L. Fox, sole inventor; to same assignee) relates to treating a normally nongaseous branched chain satd. aliphatic hydrocarbon (such as isooctane for the production of a *mercerizing assistant*) with a gaseous mixt. of SO_2 and Cl (suitably at 40°). U. S. 2,174,509 relates to reactions such as that for the production of a disulfonyl chloride from cyclohexane by treatment with admixed SO_2 and Cl. Numerous uses of the products of these patents and their derivs. are specified, as *wetting*,

emulsifying, weed-killing, fungicidal, lubricating or *tanning agents.*

Reaction of alicyclic hydrocarbons with chlorine and sulfur dioxide. Arthur L. Fox (to E. I. du Pont de Nemours & Co.). U. S. 2,174,506, Sept. 26. For effecting reactions such as the production of sulfonyl chloride derivs., etc., an alicyclic compd. such as dodecylcyclohexane is treated with a gaseous mixt. of SO_2 and Cl. Numerous examples for producing *wetting agents*, etc., are given.

Condensation products suitable for textile treatments, etc., and derived from carboxylic acids. Hermann Schuette and Max Wittwer (to I. G. Farbenind. A.-G.). U. S. 2,174,760, Oct. 3. By the reaction of stearic acid or various other carboxylic acids under pressure successively with reagents such as ethylene oxide and propylene oxide (suitably at 130–140°), products are obtained suitable for use as *wetting, washing, dispersing, leveling,* or *softening agents* or the like in the textile, paper, lacquer, leather, rubber or other industries or in cosmetics or pharmaceutical prepns. U. S. 2,174,761 relates to condensation products which may be produced by heating hydroxy compds. such as cetyl alc. or dodecyl alc. successively with ethylene oxide and propylene oxide, with or without subsequent treatment with a sulfonating reagent. U. S. 2,174,762 relates to the production of condensation products, for various like uses, by treating an amine such as dodecylamine or cetyl amine, successively, with reagents such as epichlorohydrin and propylene oxide or with propylene oxide and ethylene oxide. Numerous uses of the products are mentioned.

Sodium silicate detergents. Walter S. Riggs and Clarence W. Burkhart (to Pennsylvania Salt Mfg. Co.). U. S. 2,175,781, Oct. 10. A process of making a Na silicate-contg. product capable of use as a detergent comprising a reaction product whose mol. ratio of Na_2O to acidic oxide is from approx. 1:1 to 2:1 comprises mixing together, in the absence of sufficient water to dissolve a substantial portion of the reactants, a Na sub-silicate contg. a higher mol. ratio of Na_2O to acidic oxide than 1:1 and higher than that of the product desired, and a Na compd. selected from the group consisting of water glass, $NaHCO_3$, NaH_2PO_4, Na_2HPO_4, a Na borate having a mol. ratio of B_2O_3 to Na oxide greater than 1:1, the reactants being present in such mol. proportions that the ratio of Na_2O to acidic oxide of the reactants in the reaction mixture is approx. from 1:1 to 2:1, and treating while stirring the mixt.

Polyamides suitable for use in coatings, etc. Wallace H. Carothers (to E. I. du Pont de Nemours & Co.). U. S. 2,174,619, Oct. 3. From initial materials such as fumaric acid and decamethylenediamine and the like there are obtained (suitably by heating with phenol at 150–160° and vacuum distn. of the phenol) polymeric reaction products of compds. consisting substantially solely of equimol. proportions of bifunctional polyamide-forming reactants the sum of whose radical lengths is at least 9, the amide-forming groups in the reactants being attached to aliphatic C atoms, at least one of the reactants contg. an unsatd. C—C linkage of the nonbenzenoid type in the chain sepg. the amide-forming group. Numerous examples are given.

Bonded carbon articles. Edwin F. Kiefer (to National Carbon Co.). U. S. 2,174,886, Oct. 3. Molded carbon members are bonded with a cement contg. essentially a resinified deriv. of furfuryl or furfural alc. or their mixts. U. S. 2,174,887 relates to baked carbon articles such as parts of chem. app. the pores of which are substantially filled by a similar resinified product.

Saturated gaskets of paper or the like. Leon E. Hoogstoel (to Behr-Manning Corp.). U. S. 2,175,773, Oct. 10. App. is described, and a method of making gaskets of predetd. size and shape from paper-like webs including cellulose fibers in an amt. to cause the webs to change dimensions upon satn. with a binder soln. which swells cellulose, comprising satg. the web. with a binder soln. contg. a flexibilizing agent, and a material selected from the classes consisting of bone glues, hide glues and casein, drying the satd. web to produce a satd. web at least the cross dimension of which differs substantially from the same dimension of the untreated web, cutting gaskets of definite predetd. size and shape therefrom and subsequently tanning the binder within the gaskets so cut to produce gaskets of the same size and shape as the gaskets cut from the untanned web whereby the satg. materials in the waste remain untanned and may be recovered for reuse and whereby the scrap paper may be reprocessed. Glycerol or sorbitol may be used as the flexibilizing agent. Cf. *C. A.* 33, 2252[5].

Saturated paper gaskets. Elmer C. Schacht and Nicholas E. Oglesby (to Behr-Manning Corp.). U. S. 2,175,774, Oct. 10. App. is described, and a process of making satd. paper gaskets of definite size and shape from paper contg. cellulose fibers in an amt. which will cause the paper to change dimensions upon satn. comprises swelling the paper to a degree controlled in accordance with the characteristics of the paper and the binder used for satn. thereof, cutting a blank from the paper in such a swollen condition and subsequently satg. the blank with a binder contg. an agent which swells cellulose whereby the final dried satd. article has substantially the same shape and the same dimensions in the plane of the paper as the pre-cut blank. The binder used may comprise a soln. contg. glue and sorbitol. Cf. *C. A.* 33, 2252[5].

Friction facing suitable for clutches. Morton F. Judd (to Raybestos-Manhattan, Inc.). U. S. 2,175,399, Oct. 10. App. is described, and a method of forming a friction element suitable for a clutch facing, which comprises, convolutely winding a composite strip comprising a thickness of nonwoven fibrous material and a thickness of woven textile fabric, the strip being impregnated with a thermoplastic heat-hardenable binder compn., shaped to provide longitudinally extending recessed and projecting portions on the opposite sides of the strip; and wound coils of interesting relationship to form an annular body while maintaining the textile fabric thereof in outward formation and subjecting the body to heat and pressure to consolidate it and harden the binder thereof.

Molded friction materials suitable for brake and clutch facings, etc. Wm. Nanfeldt (to World Bestos Corp.). U. S. 2,175,480, Oct. 10. Asbestos fiber, PbO, albumin and friction materials such as PbO are used together.

Stabilizing glue, casein and other protein materials. Sidney Musher (to Musher Foundation Inc.). U. S. 2,176,038, Oct. 10. To inhibit decompn., the materials (such as sizing for paper, etc.) are mixed with an unbleached cereal flour such as oat flour or an ext. contg. water- or alc.-sol. antioxygens.

Preserving oxidizable substances. United States Rubber Products, Inc. Brit. 508,442, June 30, 1939. *Rubber, unsatd. fatty oils, essential oils, petroleum oils* and *their derivs.* such as *gasolines, soaps, aldehydes* and *synthetic resins* are preserved by incorporation therein of a small proportion, e. g., 0.1–5%, of a compd. of formula RNHR′-NHY, where R is an aryl group, R′ an arylene group and Y a COOH radical the H atom of which is replaced by an alkyl, aryl or aralkyl group, which may be substituted or unsubstituted. The compds. may be formed by the interaction of a primary-amino-substituted diarylamine and a chlorocarbonic ester. In an example, *p*-aminophenyl-*p*-tolylamine in alc. soln. is treated with Et chlorocarbonate in the presence of AcONa to yield *p*-(*p*-tolylamino)phenylurethan.

Chloromethyl compounds of sulfonamides. I. G. Farbenindustrie A.-G. Brit. 508,794, July 4, 1939. A sulfonamide that has at least 1 exchangeable H atom at the amide N and also contains a hydrocarbon radical having at least 4 C atoms, which may contain substituents and (or) may be interrupted by at least 1 O, S or N atom, is caused to react with CH_2O or a polymer thereof and HCl at ordinary or raised temp., or HCl is caused to react with a methylol compd. obtained by the reaction of CH_2O or a polymer thereof with a sulfonamide as defined above. The products may be used for the *treatment of textiles, leather, paper, plastic masses,* etc. Among examples, (1) octadecylsulfonamide (obtainable by the action of liquid NH_3 on octadecylsulfonyl chloride) is dissolved in methylene chloride, paraformaldehyde (I) is added and HCl intro-

ed into the cold soln., (2) p isododecylcyclohe oil is
lensed with Na chloroeth ulfonate, the product
eated with PCl_5 and then with liquid NH_3, and the
lting sulfonamide is caused to react with I and HCl in
), and (3) octadecylsulfonomethylolamide is treated
HCl in methylene chloride.

luminum sound records. Junius D. Edwards (to
ninum Co. of America). U. S. 2,174,720, Oct. 3.
und-recording blank comprises an Al disk coated with a
y acid having lubricating properties such as ricinoleic
(which may be mixed with mineral oil).

Removing enamel from enameled articles. Max Zimmermann and Werner Funke (to I. G. Farbenind. A.-G.). U. S. 2,174,454, Sept. 26. For removal of the enamel, enameled articles are subjected to the action of an aq. soln. of HCl and H_2SO_4 in about equal amts. (suitably about 20% each) at a temp. of about 20–30°.

Smoke-screen materials. James F. Booker and Roger L. Annis (to Intermetal Corp.). U. S. 2,175,790, Oct. 10. $TiCl_4$ or $SnCl_4$ is used in chem. combination with a S chloride and with a substantial excess of one of the chlorides.

14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

ifty years of water-works advance. M. N. Baker. . *News-Record* **123**, 617–18(1939).—Conditions are pared in regard to the no. of water-works systems, no. of water- and sewage-treatment plants and the noid death rate. R. E. Thompson

iltered water for Chicago. Loran D. Gayton. *Eng. s-Record* **123**, 682–5(1939).—In the 320-million gallon day filter plant now under construction, there will be filters and the sedimentation tanks will be 32.5 ft. , with intermediate settling floors at half the depth. mixing period will be 45 min. and the settling period s. If acid-treated Na silicate is employed to strengthen floc, av. filtration rates of 2.5 gal. per sq. ft. per min. inter and 3 gal. in summer, with max. of 3 and 4 gal., ., may be employed: otherwise, the av. and max. s should not exceed 2 and 2.5 gal., resp. The water l for continuous sludge removal and for filter washing be reclaimed. A surface-washing system will be pro- d. R. E. Thompson

hanghai (China) Waterworks Co., Ltd., Annual Re-, 1938. W. P. Rial. 53 pp.(1939).—The av. daily sumption was 46.36 million gallons. The turbidity of Whangpoo River water was reduced from an av. of to 20 p. p. m. with an av. dose of 0.91 grain per gallon lum. All the water applied to the rapid sand filters prechlorinated, the av. dosage being 1.01 p. p. m. he total output, 29% was from the slow sand plant and 6 from the rapid sand plant. The av. rates of filtration e 1.71 and 100 gallons per sq. ft. per hr., resp. The no. of days between the cleaning of the slow sand units 16.56 and the water used for washing the rapid sand rs averaged 2.59%. Larvae of *Diptera chironomus* in appeared in the effluent of some of the rapid sand rs (cf. *C. A.* **32**, 7621[6]) and their presence was corred with an increase in the effective size of the sand. Reing the effective size by adding fresh sand corrected the ible. In addn. to prechlorination, 0.35 p. p. m. Cl applied to the rapid sand filter effluent and 0.24 p. p. at the main engines. Consumers' complaints regarding er quality numbered 27, 7 of which referred to palata- y. Of 1509 samples of water from the distribution em examd. for *B. coli*, 95% were neg. in 100 cc., 3.8% in 100 cc., 0.7% in 10 cc., 0.4 in 1 cc., and 0.1 in 0.1 The cost of steam per 1000 lb. was $1.6653 and B. t. u. sumed per lb. of steam produced averaged 1828. The cost per million B. t. u. was $0.73. R. E. T.

lkaline ground water of slight hardness at Bucharest. is Stanisavlievici. *Gas- u. Wasserfach* **82**, 697–700 39).—The analyses of waters contg. Na_2CO_3 which oc- in London, East Prussia and Westphalia are given and trasted with that of a deep artesian well at Bucharest. latter water was well adapted for drinking, process boiler feed water. Wells sunk within city limits re- e strict supervision to ensure satisfactory bacteriol. lity, but are very desirable in case of air raids. R. W. Ryan

olloidal substances in natural waters. M. A. Kulakov. *l. acad. sci. U. R. S. S., Sér. géograph. géophys.* **1938**, 1, 73–91; *Khim. Referat. Zhur.* **2**, No. 2, 26(1939).—content of the colloidal substances in water was detd. the method of ultrafiltration. In Lake Baikal and its tributaries the colloid content varied from 8×10^{-5} to 136×10^{-5}%, and in the Leningrad lakes from 5×10^{-5} to 103×10^{-5}%. Usually the natural waters contain more org. colloids (humic substances) than inorg. colloids. The soln. of electrolytes is the dispersion medium, and such compds. as SiO_2, $Fe(OH)_3$ and $Al(OH)_3$, and the humic substances are the dispersed phase. The sources of colloids in the hydrosphere (weathering, the action of tides, the breaking up of rock formations in the channel, formation of colloidal $Fe(OH)_3$ by the hydrolysis of the Fe salts, etc.) and the significance of the colloidal-chem. properties of natural waters in chem., phys. and hydrological investigations are discussed. W. R. Henn

Expression of the results of chemical analyses of well waters and a method of analysis. V. I. Malyshev. *Azerbaĭdzhanskoe Neftyanoe Khoz.* **1938**, No. 7–8, 15–17; *Khim. Referat. Zhur.* **2**, No. 3, 79(1939).—The alky. of water should be expressed in 4 components: bicarbonates, carbonates, org. acids and the borate compds. Only the gravimetric method can be used for the detn. of sulfates. All results of analyses must be converted to percentage by wt. W. R. Henn

Electrometric determinations of the oxidation-reduction potential in water wells. T. I. Nekhotenova. *Microbiology* (U. S. S. R.) **7**, No. 2, 186–97(1938); *Khim. Referat. Zhur.* **2**, No. 2, 68–9(1939).—The usual methods used for the detn. of the O content (Winkler), of the oxidation ability and of the biol. requirements for O are not sufficient for the characteristics of the oxidation-reduction conditions of the medium which contributes to the development of bacteria. Simple electrometric cells are proposed which are lowered directly into the well for the measurement of the p. d. on a Pt electrode (immersed in the water under investigation) relative to the calomel electrode. The app. was tested on tap water, well water and on a room aquarium. A const. p. d. value in waters with an established O equil. (aquarium) is obtained almost instantly, and in 1–4 hrs. in samples of fresh water. The values of E_h obtained in different river waters at different depths and at different points varied from 0.1356 to 0.5307. Parallel detns. of pH, O_2 (according to Winkler), O consumption and H_2S were made. The proposed method gives a new empirical means of detn. of the biol. conditions existing in a given well. W. R. Henn

The physical-chemical state of the hot springs at Monfalcone. Bartolomeo Doro. *Ann. chim. applicata* **29**, 374–80(1939); cf. *C. A.* **33**, 8863[8].—The observed f.-p. lowering, 0.777°, of these waters does not agree very well with the value calcd. by applying the theory of Debye and Hückel, 0.674°, based on the coeff. of activity of the waters. A. W. Contieri

Manganese in a thermal spring in West-Central Utah. Eugene Callaghan and H. E. Thomas. *Econ. Geol.* **34**, 905–20(1939).—The Abraham Hot Spring has a total discharge of over 1200 gallons a min. at temps. as high as 182°F. Five complete analyses of these alk. waters show about 3900 p. p. m. dissolved solids, high in Na, Ca, Cl and sulfate. The dome built by the spring contains seams about a ft. thick, from which 715 tons of ore averaging 20% Mn was mined. The seams consist chiefly of pyrolusite, psilomelane, limonite and calcite. The present Mn

content of the waters is 0.3 to 1.2 p. p. m. and the Mn deposition must have constituted a distinct episode in the history of the spring. The source of the Mn is unknown. An analysis of the ore is given; the high BaO content (4.3%) is noteworthy. Michael Fleischer

Routing nightmares of water conditioning. R. E. Hall, E. P. Partridge and T. H. Daugherty. *Mech. Engr.* **61**, 715–21 (1939).—Suggestions for the prevention of cracking in upper tube ends of boiler water tubes are, maintenance of the sulfate:alky. ratio above 3, maintenance of an equally important Cl:alky. ratio (value not given), feeding of lignin or certain of the tannins, or sulfite waste liquors if obtainable. The design and construction of the boiler should be checked to make certain that no portions of drum or tubes are supported by other than intended means. The formation of steam line and turbine deposits may be caused by fog carryover resulting from too great velocity of steam and water as it is discharged from the steam cross-over tubes into the steam take-off drum. Installation of addnl. cross-over tubes reduces this steam velocity. New boilers can be effectively and rapidly cleaned from grease, etc., by use of 3 lb. of Calgonite (40% $NaPO_3$, 15% $Na_3PO_4.H_2O$, 40% Na metasilicate pentahydrate, and 5% NaOH), 0.6 lb. of NaOH, and 0.1 lb. of dispersive tannin per 1000 lb. water. The use of 2 lb. of Na hexametaphosphate per million lb. of raw water is effective in prevention of scale in condensers. Na Al silicate scale formation can be prevented by removal of the Al portion from the feed water. Treatment with CO_2 to lower the pH value to 7, at which the alumina will ppt. out, is recommended. This ppt. can then be filtered from the water. Desuperheating should be carried out by addn. of only so much water that it will not be entirely evapd. and thereby prevent scale or ppt. formation at the point of evapn. H. E. Messmore

Comparison of MacConkey's broth and standard lactose broth as media for detection of coliform organisms in water. M. H. McCrady. *Am. J. Pub. Health* 29, 1250–7 (1939).—The MacConkey presumptive (presence of gas within 48 hrs.) did not prove to be, in general, a satisfactory indication of the presence of coliform organisms. False presumptives (or at least presumptives from which such organisms were not isolated by means of the usual complete confirmation procedure) constituted 2, 20, 39, and 40% of all MacConkey presumptives encountered by the Maryland, Quebec, Toronto and New York labs., resp. Complete confirmation of MacConkey presumptives yielded about as many coliform isolations as did like confirmation of the larger no. of lactose broth presumptives, or of brilliant green bile confirmatory gas pos. The economy in no. of presumptives to be confirmed obtained through the use of MacConkey broth, however, did not appear to surpass that which was secured in a previous study, through the use of a fuchsin broth (cf. *C. A.* **32**, 1370[8]). The effect of inhibiting agents employed in these 2 media upon coliform organisms that may be contained in finished waters has yet to be detd. On the whole, the procedure employing lactose broth and confirmation (gas only) in secondary brilliant green bile appeared to yield more satisfactory results than the other procedures. In the Toronto lab., a no. of false positives were encountered in brilliant green bile as well as in MacConkey broth; but there also the procedure employing brilliant green bile, whether or not followed by complete confirmation, proved to be as satisfactory or more so than that in which MacConkey broth was used. Eight references. J. A. K.

A sewage-works laboratory facilitates operation. Norman J. Howard. *Eng. Contract Record* **52**, No. 42, 18–19, 30 (1939).—A general discussion. R. E. T.

Gas hazards in sewerage systems. A. T. Byram. *Eng. Contract Record* **52**, No. 42, 26–8 (1939).—Means of avoiding explosions and gas hazards in sewers and sewage-disposal plants are discussed. R. E. Thompson

Methane from sewage. The Croyden plant. J. P. Lawrie. *Chem. Products* **2**, 155–6 (1939); cf. *C. A.* **33**, 8869[9].—At the Beddington Sewage Works and Farm of the County Borough of Croyden serving a population of 330,000 the total dry-weather flow of sewage is approx. 11½ million gals. daily and the total wet sludge treated amounts to about 300 tons per day. This is utilized on farm land, at the av. rate of 2 lb. of wet sludge per sq. yard per day. This dries in 2 weeks during favorable weather and is then ploughed in. The cost of disposing of the digested sludge on land amounts to 2.008 pence per ton. The sewage-treatment plant includes sedimentation tanks, 3 processes of biol. type, percolating filters and a battery of 6 cork-insulated digestion tanks with a gross capacity of nearly 4,000,000 gals., giving a digestion period of 8 weeks. One heater is arranged to each pair of tanks and the sludge is circulated and heated to 79–85°F. There is a sep. gas holder of sufficient capacity to cover the periods of min. gas evolution. The gas produced contains CH_4 69%, CO_2 30%, B. t. u. 690 gross. The quantity of CH_4 produced is 300,000 cu. ft. daily. Leopold Scheflan

Power from sludge gas at Albuquerque. W. W. Wheeler. *Eng. News-Record* **123**, 842–3 (1939).—The new 5-million gal. per day sewage-treatment plant consists of revolving screens of the comminutor type, machines for feeding lime and chlorinated copperas or other coagulants, a flocculating basin equipped with revolving paddles, a clarifier with sludge-removing and scum-skimming mechanisms, 3 trickling filters contg. 6 ft. of crushed gravel, primary and secondary sludge-digestion tanks and drying beds. The sludge gas is used in a gas engine connected to an elec. generator, in the lab., and for heating purposes. The jacket water from the engine is circulated through the primary digestion tank and the flocculation basin. The cost of the plant was $233,500. R. E. Thompson

The problem of (sewage) sludge disposal. Wm. Raisch. *Eng. Contract Record* **52**, No. 42, 34 (1939).—A brief discussion, with particular reference to incineration. R. E. Thompson

Relation of industrial wastes to sewerage problems. Darwin W. Townsend. *Eng. Contract Record* **52**, No. 42, 36, 38 (1939).—A discussion of the effects of industrial wastes on sewers, sewage works and treatment processes, their admission to or exclusion from sewer systems and pretreatment of specific types of wastes prior to admission to sewers. R. E. Thompson

Proportioning device (suitable for use in treating boiler feed water with scale-reducing substances, etc.). Emil J. Formhals (to Formhals Engineering Co.). U. S. 2,174,784, Oct. 3. Various structural and operative details of a device for proportioned measuring and pumping.

Thickening sewage sludge. John R. Downes and Thomas R. Komline. U. S. 2,174,873, Oct. 3. An arrangement of app. is described, and a method of thickening sewage sludge which involves freezing it, thawing the frozen sludge and draining off water released by the freezing and thawing.

Marine type pressure separator for separating oil from oil-polluted water. Edward W. Green and Geo. R. Unthank. U. S. 2,175,563, Oct. 10. Various structural details.

15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

M. S. ANDERSON AND K. D. JACOB

The humification reactions occurring in composting straw. L. Schulte. *Bodenkunde u. Pflanzenernahr.* **14**, 297–322(1939).—In practical scale expts., soaked cut straw with 0.7 or 1.4% dry wt. N as $CaCN_2$ or $CO(NH_2)_2$ + CaO was packed solidly or loosely for initial heating to 60–70° and then compacted in tight pits of 8.8 cu. m. capacity. After a total storage period of 8–9 months, examn. of the material indicated: Total loss in wt. was about 10% greater with the initial hot fermentation, and slightly less with the larger than with the smaller addn. of N. AcBr-insol. humus formation was apparently a little greater with the single addn. of N and hot fermentation, but when corrected for abs. values immediate compaction resulted in the greatest net formation of humus. Some slight differences in humus combinations with the 2 Ca carriers were apparent, but colorimetric studies indicated that in all cases only the brown humic acid type was present. The expt. was inconclusive in other respects, but in general the indications from similar work (cf. *C. A.* **32**, 9375[1]), that heating is undesirable and losses are smaller but less humus is formed with the greater addn. of N, are substantiated. Seventeen references. C. J. S.

Evaporation of moisture from soil in large lysimeter pots. P. L. Gow. *Hawaiian Planters' Record* **43**, 287–90 (1939). K. D. Jacob

Report of the chemistry section. R. E. R. Grimmett. *New Zealand Dept. Agr., Ann. Rept.* **1938-39**, 67-71; cf. *C. A.* **33**, 3051[7].—*Co investigations.* Samples of New Zealand ultrabasic magnesian rocks contained 67–115 p. p. m Co. Certain North Auckland soils assocd. with Co-deficient pastures contained up to 10 p. p. m. total Co, but the Co present was relatively insol., even in strong acid. Typical limestones contained 0.2–5.1 p. p. m. Co. The av. Co content of the livers of bush-sick sheep was about 0.04 p. p. m. or less, but for healthy animals more than 0.1 p. p. m. A similar difference was observed for cattle. There was no evidence of Cu deficiency assocd. with bush sickness in the North Island. *Arsenic in the Reporoa district.*—Representative samples of soil to 9-in. depth in pasture lands contained 0.0008–0.525% As. Mud deposits contained 0.0068–1.9% As, either as sulfides or in combination with Fe in impure limonite. In 39 samples of water from springs, streams and surface depressions the As_2O_3 content ranged from a trace to 2.6 grains/gal. *Chem. control of ragwort.*—$NaClO_3$, either as a spray or as lime-chlorate dust, was more effective in killing the roots of ragwort when it was applied in wet weather than in dry periods and winter applications seemed to be more effective than those made at other seasons. The treatment did not prevent the germination of seeds that were already on the ground. Applications of 300 lb. or more per acre caused a reduction in the clover and an increase in the Yorkshire fog on the plots. Injections of chlorate into the soil or applications on the soil surrounding the plants were not as effective as those applied to the foliage in the usual way. K. D. Jacob

[Report on] chemistry. N. Craig. *Mauritius Dept. Agr., Ann. Rept. Sugar-Cane Research Sta.* **8**, 33–46 (1937)(Pub., 1938); cf. *C. A.* **32**, 1031[7], 1032[1].—In tests on a series of normal *Mauritius soils*, negligible differences in pH values were obtained by the collodion bag and the Kuhn colorimetric methods. With the Volk-Truog method (cf. *C. A.* **28**, 5570[1]), 2 successive 5-min. extns. using 225 cc. *N* NH_4OAc for each extn. to each 30 g. soil extd. 98% of the total exchangeable K, whereas a 5-min. treatment with double the quantity of NH_4OAc extd. only 82%. The Truog method (cf. *C. A.* **31**, 6795[1]) gave low results for available P in highly laterized, immature soils that were rich in org. matter, because of failure of the method to dissolve org. P compds.; Dyer's citric acid method and Hance's (cf. *C. A.* **31**, 7161[2]) rapid chem. method gave higher results on such soils and Hance's method was preferable because it was easier and quicker in operation. The immature, sugar-cane soils of Lallmatie and Bon Accueil are deficient in available P, very low in exchangeable K and exceptionally high in org. matter (16.2–20.5%). In preliminary expts., chem. analysis of the leaves of the growing plants gave promise as a method for the detn. of the *fertilizer requirements of sugar-cane soils.* K. D. Jacob

Report of the agricultural chemist. E. H. Gurney. *Queensland Dept. Agr. and Stock, Ann. Rept.* **1936–37**, 94–109; cf. *C. A.* **31**, 5419[4].—Mech. and chem. analyses and properties of numerous samples of *Queensland soils* are tabulated, as well as chem. analyses of numerous samples of *Queensland pasture grasses, roughage, herbage, sorghum seed and shrubs. Ibid.* **1937-38**, 130–44.—Analyses of soils, pasture grasses, roughage, herbage, shrubs and *grains* are given. Figures on the *seasonal fluctuations of HCN in several varieties of Queensland plants* are tabulated. K. D. Jacob

The effect of lime and of drilling superphosphate on soils on which subterranean clover does not thrive. E. F. Fricke. *Tasmanian J. Agr.* **10**, 110–19(1939).—Pot cultures with soils on which subterranean clover did not thrive showed that the majority of these soils responded to treatment with com. lime and to superphosphate close to the seeds as in drilling. Lack of response to lime in the first yr. may be followed by a large response in the second or subsequent yrs. J. R. Adams

A lysimeter study of losses of applied potash by leaching from an acid soil. P. L. Gow. *Hawaiian Planters' Record* **43**, 263–76(1939).—In ratoon sugar-cane pots, K applied as either neutral salt or carbonate was not leached to any serious extent. When K was applied to cane pots at the same time as $(NH_4)_2SO_4$, the leaching of K was not significantly greater than that which occurred when the application of K was delayed until after nitrification of the $(NH_4)_2SO_4$ had taken place. Somewhat lower losses of K were indicated in uncropped pots which did not receive K until after nitrification had occurred. No important conservation of K was gained by the use of K_2CO_3 in cane pots, but lower losses of K were indicated by the use of K_2CO_3 in uncropped pots. Retention of applied K by an acid soil in the absence of vegetation was poor, but in the presence of cane was very good, indicating highly efficient uptake of K by ratoon cane. Seriously increased loss of K by leaching as a result of long-continued use of acid-forming fertilizers appears unlikely to occur in soils cropped to cane. K. D. Jacob

Soluble phosphoric acid in soils fertilized with phosphates and treated with steam. P. N. Koshel'kov. *Trudy N. I. U. I. F., Sbornik "Fosfor. Udobr. i ikh Kachestva"* No. **141**, 261–77(1938); *Khim. Referat. Zhur.* **2**, No. 2, 98(1939).—The changes in the water-sol. P_2O_5 taking place when the soil is fertilized with different phosphates (superphosphate, phosphorite, phosphate of Fe) and when it is treated with steam were investigated. The soly. curves of P_2O_5 and the method of the hot dialysis and electrodialysis at different ratios of soil to water were used. Besides P_2O_5 the amt. of Ca in the soln., the elec. cond. and the dry residue were detd. The decrease of the P_2O_5 content is connected with the increase of the dispersion ability of the soil when treated with steam. The mol.-dispersed form of P_2O_5, which passes into the ultrafiltrate (through the collodian sack), and the colloidal peptized form of P_2O_5 (not passing through the sack) are differentiated by different assimilation. W. R. Henn

Availability to plants of phosphoric acid of the difficultly soluble phosphates in saline soils. E. I. Ratner. *Trudy N. I. U. I. F., Sbornik "Fosfor. Udobr. i ikh Kachestva"* No. **141**, 239–55(1938); *Khim. Referat. Zhur.* **2**, No. 3, 64–5(1939).—The mobility of P_2O_5 of $FePO_4$ and of $AlPO_4$ increases considerably with the increase of the percentage content of exchangeable Na. The mobility of P_2O_5 of the phosphorites changes very little on increase of Na in the soil. The effect of exchangeable Na on the mobility of P_2O_5 of the phosphorite in chernozem is consider-

ably greater than in saline soils. With a high content of exchangeable Na in chernozem the mobility of P_2O_5 of apatite increases, but the satn. with Na decreases the quality of the soil as a medium for the growth of plants. On poor humus horizons of saline soils a noticeable increase of the soly. of P_2O_5 of phosphorite takes place only after substitution of 40% of the total exchangeable bases by Na. In saline soils the P_2O_5 in the phosphates of the sesquioxides is sufficiently mobile and is available to plants. The greater the content of the exchangeable Na in the soil the greater the mobility of P_2O_5 of these phosphates. Addn. of gypsum to the saline soils causes a sharp decrease of the availability to plants of P_2O_5. A large amt. of org. substances increases the effect of exchangeable Na on the soly. of P_2O_5 of the difficultly sol. phosphates. The effect of exchangeable Na on the availability of P_2O_5 in chernozem is very small in comparison with the effect of an equiv. amt. of exchangeable H. W. R. Henn

Methods for the investigation of phosphorus fertilizers. A. V. Sokolov. *Trudy N. I. U. I. F., Sbornik "Fosfor. Udobr. i ikh Kachestva"* No. **141**, 87–96(1938); *Khim. Referat. Zhur.* **2**, No. 2, 98(1939).—The comparative effectiveness of the P_2O_5 unit in fertilizers cannot be connected directly with the crop increase obtained. A no. of suggestions are given for the planning of expts. in which the different forms of P fertilizers are compared. W. R. Henn

Importance [to plants] of elements occurring in traces only. C. Krügel and H. Heinrich. *Superphosphate* **12**, 141–5, 161–4(1939).—A review and discussion. K. D. Jacob

Urea as a source of nitrogen for potatoes in the Hastings, Florida, area. B. W. Hundertmark and R. V. Allison. *Am. Potato J.* **16**, 322–9(1939).— In expts. on Bladen fine sandy loam and Portsmouth fine sand soils, 50% of the N in a mixed fertilizer for potatoes was derived from urea instead of natural org. sources, with the other half supplied as $NaNO_3$ 15 and $(NH_4)_2SO_4$ 35%, without appreciably affecting the yield. The use of 20% of the N in the form of natural org. compds., when the balance was supplied by a mixt. of equal parts of urea and $(NH_4)_2SO_4$, did not affect the yield of tubers as compared with either the check treatment or all-urea mixts., though it did favorably influence the phys. condition and the drillability of the mixt. No stimulation in growth of vine or consistent increase in yields of tubers could be attributed to the use of a mineral supplement of Mn, Zn and B. K. D. Jacob

Variations in the cooking quality of potatoes as influenced by fertilizers. P. T. Blood and J. L. Haddock. *Am. Potato J.* **16**, 329–35(1939).—As compared to the results obtained with a 4:8:7 fertilizer mixt., the av. relative yield was increased but the cooking quality of the tubers was decreased by the use of a 4:8:14 mixt. in a 6-yr. expt., whereas with a 4:16 7 mixt. the yield and cooking quality were both increased. Potatoes that received no fertilizer showed the highest cooking quality but produced the lowest yields. A small amt. of B in the fertilizer seemed to improve the general external appearance of the tubers but did not increase the cooking quality. K. D. Jacob

[Report on] research botany. The early fertilizer requirements of sugar cane. H. Evans. *Mauritius Dept. Agr., Ann. Rept. Sugar-Cane Research Sta.* **8**, 58–9(1937) (Pub. 1938).—Cores were removed from the middle internodes of cane cuttings by means of a cork-borer, the holes filled with a mixt. of equal parts of urea and K_2HPO_4 and sealed with cork stoppers and the cuttings grown in moist sawdust for 3 months. As compared to the controls, the treated cuttings produced more shoots and showed much better growth of shoots and roots. Also, the leaves and stems of shoots from the treated cuttings showed higher percentages of N, P and K in the dry matter than did those from the controls. In field expts., internally treated cuttings gave better results than did either the controls or the cuttings that received the same quantity of fertilizer mixt. placed in the ground outside the cutting. NH_4 salts had a marked toxic effect when they were placed in the cutting. K. D. Jacob

1 **The prob[illegible] organic manuring—possibilities of town refuse.** E. [illegible] Rupp. *Fertiliser, Feeding Stuffs, Farm Supplies J.* **24**, 607–8(1939).—An org. fertilizer is prepd. from the household refuse of the Royal Borough of Kensington by removing the glass, metals, paper and rags, crushing, spraying with a culture soln. of bacteria and fungi and then fermenting for 16 days in large chambers made of brick and coated with bitumen. The product is a 2 nearly odorless brown powder contg. org. matter 30, insol. inorg. matter 40 and moisture 30%. In 1-yr. expts. the N in the product was usually equal to, in some cases significantly superior to, that in farmyard manure in increasing the yields of kale and sugar beets, and appeared to be about 25–50% as effective as the N in $(NH_4)_2SO_4$. K. D. Jacob

The value of the characteristics conferred on the grape vine by fertilizing. E. Vinet. *Compt. rend. acad. agr. France* **25**, 894–902(1939).—Final results of this work are 3 not given but the use of K_2O fertilizers markedly increased the K_2O content of the woody portion of the vine and the saccharine production. K_2SO_4 gave greater increases than KCl. J. R. Adams

Phosphorite flour. I. S. Pospelov. *Sel'khozgiz.* **1938**, 18 pp.; *Khim. Referat. Zhur.* **2**, No. 2, 96–7(1939).—A description of the production of phosphorite flour and of 4 soils where it is used (meadows, pastures, virgin soils). The use of phosphorite flour together with other fertilizers (manure, lime and peat), methods for their use and of the chlorinated phosphorite flour are given. W. R. Henn

The different kinds of potassium fertilizers. D. V. Druzhinin. *Sotsialist. Rekonstruktsiya Sel'skogo Khozyaĭstva* **1938**, No. 9, 127–34; *Khim. Referat. Zhur.* **2**., No. 2, 100(1939).—Sylvinite is the best form of K fertilizer for all kinds of beets in soils poor in Na. K_2SO_4 is best for potatoes, citrus fruits, grapes and tobacco. KNO_3 is the best form of K-N fertilizers for flax, tobacco and in some 5 cases for potatoes. W. R. Henn

Pineapple investigations. H. K. Lewcock. *Queensland Dept. Agr. and Stock, Ann. Rept.* **1936–37**, 85–9.—Applications of K *fertilizers* markedly increased the yield of pineapples. While no distinguishable difference in the rate of growth during the 1st 12 months was noted be- 6 tween plants receiving KCl and K_2SO_4 in the fertilizing mixts, the yield from the sulfate plots was appreciably greater than that from the chloride plots. The fertilizing value of the N and P in inorg. fertilizers was markedly superior to that of these elements in org. fertilizers. A very pronounced increase in the vigor of growth of pineapples on manganiferous soils was obtained by spraying the plants with Fe sulfate at intervals of 3–4 weeks, particularly during the winter months. Plants grown in 7 paper mulch did not exhibit the same symptoms of Fe deficiency during the winter as did those set out in exposed soil. Semiannual applications of Fe filings to the hearts of young pineapple plants corrected the Fe-deficiency symptoms, but the plants were markedly retarded in growth compared with adjoining plants that had been treated with Fe sulfate spray. There were indications that Fe present in a soil with a low buffer capacity can be 8 made available to pineapple plants by suitably adjusting its reaction, whereas it cannot be so released in a highly buffered soil. **Report of the plant physiology section.** *Ibid.* **1937–38**, 40–4.—Incidence of the *"crookneck" disease of pineapples* was markedly reduced by spraying the young plants with a soln. of H_3BO_3 at monthly intervals. K. D. Jacob

Chemical delintering and budding of cottonseeds. N. Chebotaev. *Sovet. Khlopok* **1938**, No. 5, 117–18; *Khim. Referat. Zhur.* **2**, No. 1, 60(1939).—Delintering by means 9 of 175 g. of concd. H_2SO_4 per kg. of cottonseed, for 20–30 min. at 20°, increased the crop by 1 cental/hectare. Budding the seeds after delintering increased the crop by 1.8 centals/hectare. Delintering budded seeds caused a sharp thinning of the plants and a sharp decrease of the crop. W. R. Henn

Disease control and stimulation of cane cuttings by the hot-water treatment. J. P. Martin and R. K. Conant.

Hawaiian Planters' Record **43**, 277–85(1939).—Germination was hastened, growth of the sprouts was stimulated and control of the chlorotic streak disease was favored by soaking sugar-cane cuttings in hot water (50–52°) for 20 25 min. The treatment killed all insects, either within or on the cuttings, and produced much more rapid germination and growth of shoots than did dipping the freshly cut ends of the seed pieces in 1% Ceresan soln. K. D. J.

Asparagus rust control with copper-containing sprays. H. Hülsenberg. *Nachr. Schädl Bekampf.* (Leverkusen) **14**, 65 72(1939); *Rev. Applied Mycol.* **18**, 649.—Conflicting results in the control of asparagus rust (*Puccinia asparagi*) with Cu-contg. sprays were investigated. It is concluded that effective control can be secured by the treatment of young plantings a fortnight before the expected appearance of the acidia with 2 subsequent applications; by treatment 10 days after thinning out and 1 or 2 further sprays at 3 weekly intervals; and by 3 treatments for plantings 3 years old. Oden E. Sheppard

The use of chloropicrin as a seed treatment for black rot of kale. T. J. Nugent and H. T. Cook. *Larvicide Log* **1**, 114–19(1938); *Rev. Applied Mycol.* **18**, 565.—With 0.88 ml. per l. of chloropicrin kale seeds were subjected to the gas for 24 hrs. and caused an increase of sterile seeds from 2.9 (untreated) to 79.3% and reduced the incidence of fungal and bacterial contamination from 77 to 1.6 and from 43 to 16%, resp. Germination percentages for seeds treated with chloropicrin, $HgCl_2$ and hot water were 64, 72 and 61, resp., compared with 75% for the controls. Up to 40° at a moisture content of 6.5% even 3.52 ml. chloropicrin per l. did little injury to the seeds but at 14.5% moisture practically all the seeds were killed. Oden E. Sheppard

The long-winged thrips (Scirtothrips longipennis Bagn.) and its control in greenhouses. H. Andison. *Proc. Entomol. Soc. Brit. Columbia* No. **34**, 13 17(1938). Control of the insect on begonia and cyclamen plants was best obtained by spraying at 7–10-day intervals with 1 mixt. contg. 3 oz. of a kerosene-linseed oil soap emulsion to 1 gal. water with 1–2 teaspoons of nicotine sulfate per gal. of spray soln. The stock emulsion is prepd. by dissolving 1 oz. linseed oil soap in 5 oz. hot water, adding 10 oz. kerosene and agitating until emulsification is complete. Volck oil, Paris green and molasses-nicotine sprays caused slight to severe burning of the foliage which increased as the successive applications were made. Naphthalene and nicotine dusts were ineffective. K. D. Jacob

Control of canary fly. P. H. Thomas. *Tasmanian J. Agr.* **10**, 152 3(1939).—The substitution of a lime sulfur spraying for the first of 2 nicotine sulfate sprayings is not as efficient in the control of canary fly as the double spraying with nicotine. J. R. Adams

The pomegranate fruit butterfly (Virachola livia Klug)—morphology, life history and control. A. D. Hanna. *Ministry Agr. Egypt, Tech. Sci. Service, Bull.* **186**, 54 pp. (1939).—From the standpoint of economy and efficiency, the insect was best controlled by spraying the pomegranate bushes with a mixt. of Na_2SiF_6 125, lime about 140, casein 12, flour 25, Quena mud 380–500 g. and water 4 gal., applied at the rate of 2 gal./tree for the 1st spraying, 1 gal. for the 2nd, 3rd and 4th sprayings, resp., and 0.5 gal. each for the 5th and 6th sprayings. K. D. Jacob

Biology and control of the oak leaf roller (Tortrix viridana L.) in Westphalia. E. Erler. *Anz. Schädlingskunde* **15**, 85–93, 105–8(1939).—This moth larva, becoming increasingly important as a pest of oak, is effectively controlled only by chem. methods. Expts. were made with 3 com. dusts. Forestit, a contact poison (cf. Marcus, *C. A.* **27**, 5875[1]), gave 60–70% control. Detal, a dinitrocresol prepn., after 4 days, showed that 100% of the larvae were killed, and the residue was quite apparent despite a heavy shower on the 2nd day after dusting. Forstesturmit, a Ca arsenate poison contg. about 10% active component, gave 50% max. kill. Thus Detal is the only poison of the 3 tested giving satisfactory and economical control. Edwin J. Seiferle

Oil emulsions for the destruction of winter pupae of the eudemis, a European vine moth. F. Stellwaag. *Anz. Schädlingskunde* **15**, 97–105(1939).—The eudemis, *Polychrosis botrana*, a most important pest of *grape*, overwinters as the pupa in a cocoon, so the problem involved in winter control is to penetrate the cocoon and wet the pupa. Com. contact poisons alone do not do this. A com. lubricating oil soap added to the soln. at 0.5% assisted in wetting the cocoon but its use is uneconomical and it sometimes injures the foliage. Another com. prepn., 2002 N, at 0.1%, concn. wetted the pupae, but when used at 0.2% with 5 different contact poisons produced no kill because of rapid drying. Quick breaking mineral oil emulsions possessed all desirable properties. In lab. expts. 100% kill was attained by 2% oil emulsion (I) + 0.2% com. nicotine (II), I + 0.3% crude nicotine (III), I + 2% com. pyrethrum (IV) (pyrethrin content unknown), I + 0.5% rotenone, 3% oil emulsion (V) + 0.2% III, and V + 1% IV. The sepd. emulsion is inactive; thorough stirring is therefore necessary to prevent demulsification. Field expts. were made by spraying the vines and placing over them wire screen cages 9 or 18 m. by 2 m. to prevent loss of adult moths. Oil emulsion + 0.15% II sprayed on 44 vines gave 100% kill, for on 182 first buds no larvae were found. On untreated vines 201 larvae were found on 174 buds. Oil emulsion + 2% IV on 88 vines also gave 100% control. I + II at 0.2 and 0.3% concn. sprayed in large-scale field expts. produced a considerable reduction in no. of moths, but did not reach the desired 95% control. Greenhouse expts. with oil emulsion and special field expts with 2, 4 and 6% oil emulsions + 0.2% II showed no injury to the plants. I + 0.15% nicotine rapidly killed the moth larva, *Oenophthira pilleriana*, and oil emulsions were effective against the mites, *Epitrimerus vitis* and *Eriophyes vitis*, all grape pests. Edwin J. Seiferle

The control of mole crickets with barium fluosilicate. A. Kassab. *Ministry Agr. Egypt, Tech. Sci. Service, Bull.* **193**, 13 pp.(1939).—A bait composed of $BaSiF_6$ 5 and water 25 parts per 100 parts of grain is as effective as a similar bait contg. 5 parts Zn_3P_2 in controlling the mole cricket (*Gryllotalpa* sp.). The $BaSiF_6$ bait is not as rapid as the Zn_3P_2 bait in its lethal action but both baits have the same ultimate effect. It has the advantage over the phosphide bait in that it is insol. in water, odorless, easily handled and harmless to the leaves of plants. The $BaSiF_6$ bait loses its effectiveness in 9 10 days after its prepn. A dose of 100 mg. $BaSiF_6$ was lethal to hens weighing approx. 1.5 kg., whereas the fatal dose for pigeons was 170 mg. K. D. Jacob

Apple black spot (Venturia inaequalis) investigations. J. O. Henrick. *Tasmanian J. Agr.* **10**, 150–1(1939).—In efforts to eradicate apple black spot, infected leaves were sprayed with solns. of $CO(NH_2)_2$, $(NH_4)_2SO_4$, NH_4Cl, $(NH_4)_2CO_3$, K_2SO_4, KCl and com. lime sulfur. The ammonia compds. increased the rate of leaf decompn. Under the dry conditions prevailing all the leaf treatments appeared to have an inhibiting effect on ascospore formation both in the field and lab.-field trials. J. R. A.

Report of the veterinary laboratory, Wallaceville. C. S. M. Hopkirk. *New Zealand Dept. Agr., Ann. Rept.* **1938 39**, 23–33.—*Arsenic poisoning of cattle.*—Administration of 4 grains As (as Na arsenite) daily for 3 days caused no increase in the As content of the milk and urine of a heifer. This was followed after 10 days by 3 successive daily administrations of 16 grains As and the death of the animal occurred 3 days later. Mud, contg. approx. 3.5 grains As_2O_3 per oz. (partly in the form of the sulfide), from farms in the Reporoa district on which mortalities, supposedly due to As poisoning, had occurred, was fed to a steer at the rate of 20 oz. daily for approx. 11 weeks without the development of serious symptoms. *Cu poisoning of sheep.*—Four fully grown crossbred sheep were each administered 100 cc. of a 1% $CuSO_4$ soln. daily. The livers of the animals, which died in 33–77 days, contained 1950–4030 p. p. m. of Cu on the dry basis. There was no relation between the Cu content of the livers and the rapidity of death, but there was a marked similarity between the figures and those for Cu in the livers of animals that died from natural cases of *enzootic icterus*. *Effect of Zn on pigs.*

—Milk contg. 0.125–0.25 g. Zn lactate per gal. was fed to pigs at the rate of approx. 3 gal./day for about 3 months without any adverse symptoms. K. D. Jacob

[Experiments on] lime sulfur. F. B. Coleman. *Queensland Dept. Agr. and Stock, Ann. Rept.* **1936-37**, 128; **1937-38**, 127-8.—High-grade lime S (19.4–21.1% polysulfide S) showed little or no deterioration when it was stored for 7 months in tightly closed 45-gal. drums, whether the drums were full or only ⅓ full or whether they were stored in the shade or exposed to the sun. Deterioration was somewhat greater in low-grade lime S (14.2 14.7% polysulfide S), particularly when the drums were only ⅓ full. K. D. Jacob

Some common facts about pyrethrum products as insecticides. Cady S. Corl. *Soap* (*Sanitary Products Sect.*) **15**, No. 12, 115, 117, 119, 121(1939).—The present rating of pyrethrum flowers is (1) Kenya flowers 1.3–1.5% pyrethrins, (2) Japanese 0.9–1.0% and (3) Dalmatian 0.6–0.7%, and Brazilian 0.6–0.7%. Exts. of pyrethrum should be kept out of contact with Pb, Zn, brass, galvanized metal as well as glass. Other factors are reviewed. Henry H. Richardson

Leaching of sodium pyroarsenate through soil. Geo. L. Hockenyos. *Pests* **7**, No. 12, 16–17(1939).—Leaching of $Na_4As_2O_7$ was less in clay and soil with org. matter than in sandy soil. H. believes that many of the unusual results with $Na_4As_2O_7$ as a termite poison can be explained by the differences in soils. Henry H. Richardson

Action of alkylmagnesium halides on coumarin and related compds.—synthesis of 2,2-dialkyl-1,2-benzopyrans [insecticidal activity] (Shriner, Sharp) **10**. Production of coned. fodder and the cultivation of alfalfa (Demolon) **12**. Colorimetric silicomolybdic acid method for detg. nicotine [in soil] (Sutherland, *et al.*) **17**. Importance of chemistry in pest control (Roark) **13**. Treating liquid alkanes with SO_2 and Cl [to produce weed-killing and fungicidal products] (U. S. pats. 2,174,507-9) **13**. Colorimetric detn. of Al [in soil] (Rode) **7**.

Seed-germinating wafer. Albert C. Fischer. U. S. 2,175,113, Oct. 3. A wafer suitable for use with seeds such as those being tested for germinating properties comprises a float such as a cork disk carrying a contacting film of germinating soil suitable for the seed.

Apparatus (with a rotating drum) for aerating fertilizing materials, etc. Augustus J. Sackett. U. S. 2,174,896, Oct. 3. Various structural, mech. and operative details. U. S. 2,174,897 also relates to app. for treatment, as in drying and cooling, and grinding, fertilizer materials, crab shells, fish, tankage, etc.

Emulsifiable oil suitable for plant sprays, etc. Marcellus T. Flaxman (to Union Oil Co. of Calif.). U. S. 2,175,988, Oct. 10. A small proportion (suitably 0.5–5%) of undecylenic acid is used as an emulsifying, wetting and spreading agent with a mineral spray oil.

Insecticides containing 9-chlorofluorene. Houston V. Claborn and Lloyd E. Smith (to the people of the U. S. A. for free use). U. S. 2,175,109, Oct. 3. 9-Chlorofluorene is used in dusting powders or sprays.

Stable nicotine compounds suitable for insecticidal or fungicidal use. Grover D. Turnbow. U. S. 2,175,980, Oct. 10. A substantially stable compn. contains nicotine and Cu hydroxide combined with casein or albumin and CH_2O (the degree of stability being detd. by the CH_2O content).

Fungicidal oils. Edward F. English and Alexis Voorhies, Jr. (to Standard Oil Development Co.). U. S. 2,174,258, Sept. 26. A fungicidal oil suitable for impregnating wood such as cross-ties may be prepd. by destructive hydrogenation of a distillate oil and is composed substantially of aromatic, naphthenic and unsatd. hydrocarbons, has an aniline point of about −7° to −62° and a gravity of 8° to 20° A. P. I.

16—THE FERMENTATION INDUSTRIES

C. N. FREY

Hydrolysis of plant waste materials and the manufacture of alcohol from the hydrolysis products. N. Gutgerts. *Spirto-Vodochnaya Prom.* **1938**, No. 6, 4–8; *Khim. Referat. Zhur.* **2**, No. 1, 118(1939).—In the Dnepropetrovskii exptl. plant the product of the one-phase hydrolysis at 90–2° is treated at 85° with a mixt. of lime and $CaCO_3$ suspension (70 30) 20°Bé. to pH = 4.8–5.2. The duration of the process is 90 min. During the reaction aldehydes and a part of the volatile acids are blown out with air. The product is filtered-pressed, cooled to 30°, and the turbid filtrate again filtered through peat. The clear filtrate is fermented with pure-culture yeast for 36–48 hrs. The concn. of the reducing substances is 2.5–3%. Twenty-five kg. of $(NH_4)_2SO_4$ and 17 kg. of superphosphate per 100 cu. m. are added. Attempts to ferment the neutral solns. by the continuous method under lab. conditions were successful, but the method is not adaptable to plant conditions owing to the high sterility of the work required. The crude alc. is distd. off from the mash, and is stored. The residue is utilized in the yeast production department. An av. of 100–110 l. of 100% alc. is obtained from 1 ton of straw. This yield can be increased to 116–120 l. by more efficient methods. W. R. Henn

Sorbose from sorbitol. Semiplant-scale production by Acetobacter suboxydans. P. A. Wells, L. B. Lockwood, J. J. Stubbs, E. T. Roe, N. Porges and E. A. Gastrock. *Ind. Eng. Chem.* **31**, 1518–21(1939).—Studies on *l*-sorbose production from *d*-sorbitol by submerged growths of *A. suboxydans* revealed that coned. corn steep liquor was a satisfactory nutrient substitute for dried yeast ext., but necessitated the use of octadecyl alc. as an antifoam agent. In the presence of a slight excess of $CaCO_3$ which afforded satisfactory pH control, *d*-sorbitol, in concns. up to 30%, was rapidly oxidized to *l*-sorbose. Pilotplant-scale results showed no essential differences from those obtained on a lab. scale. When 20% sorbitol solns. were used under the most favorable conditions, the yields of sorbose, obtained in fermentation periods of 25 hrs. on both pilotplant- and lab. scale, were in excess of 90%. Recovery yields of cryst. sorbose approximated 70%. J. C. Jurrjens

Standardized Wohlgemuth procedure for α-amylase activity (Sandstedt, *et al.*) **11B**. Study of a new Me_2CO-resistant stock of Me_2CO-EtOH bacteria with special reference to the possibility of increasing the concn. of industrial mashes (Chumak) **11C**. Containers for holding beverages (U. S. pat. 2,175,972) **12**.

Alcohol recovery from fermented grape pomace. Enrico Prati. U. S. 2,174,707, Oct. 3. For recovery of alc. values from fermented grape pomace by distn., pomace including only about 5–20% of the fruit seeds is run through a mill with added water and the liquefied mass is passed through a continuous still in which alc. is removed.

Incorporating vitamin D with malted or fermented liquors. Jacques W. D. Chesney (to New Discoveries, Inc.). U. S. 2,175,340, Oct. 10. A coned. oil-free alc. soln. contg. vitamin D in stable form is added to a product such as beer contg. at least 0.25% alc. and also contg. dissolved CO_2, just prior to its transfer to the commercial containers in which it is to be sold.

Increasing yeast production and activity. Roger J. Williams (to Standard Brands Inc.). U. S. 2,174,543, Oct. 3. A small proportion of ethanolamine is used in yeast production to increase the rate of propagation and total yield obtainable, or in the use of yeast as for alc. production or in leavening bread to stimulate the activity of the yeast for the purpose desired. One part of ethanolamine in 12,000 parts of a culture medium gives good results.

17—PHARMACEUTICALS, COSMETICS AND PERFUMES

W. O. EMERY

Pharmacognostical study on Strophanthus cumingii A DC. from the Philippines. Jose K. Santos. *Univ. Philippines Nat. and Applied Sci. Bull.* **7**, 103–22(1939).—The bark, wood and pericarp of immature fruits and seeds of *S. cumingii* contain traces of strophanthin similarly to those of the seeds of *S. kombe*, Oliver and *S. hispidus*, DC. C. R. Addinall

An apparatus for the technical preparation of salves and emulsions containing emanation, perfume, or pharmaceuticals. B. Rajewsky and E. Burkhardt. *Kolloid-Z.* **89**, 320–4(1939).—A detailed description of an app. designed primarily for rapid prepn. of solns. of Ra emanation (I) in petrolatum. Heated petrolatum is forced through a nozzle into an aq. soln. of I, forming an emulsion. The I quickly distributes itself between the phases, mostly passing into the petrolatum; the emulsion is then cooled and seps., and the desired petrolatum soln. of I forced into a tube. Also described is a nozzle contg. an electrically charged pin for making charged fogs and suspensions. A. O. A.

Analysis of juniper berries. P. Casparis and W. Freund. *Pharm. Acta Helv.* **13**, 307–315(1938).—The following substances have been isolated: resin 8% (mainly resin acids; phenols and esters absent), essential oil, "juniperin" 0.36% (probably a mixt. of a tannin with a sugar or sugars; reactions given), a mixed *glyceride* of α-isostearic acid (?) and 15-hydroxypentadecoic acid, m. 84° (*Ac* deriv., m. 59°), *l*-malic acid, invert sugar and K salts. B. C. P. A.

New hydrocarbon from juniper oil. P. Casparis and W. Freund. *Pharm. Acta Helv.* **14**, 1 8(1939).—Oil from juniper berries collected in the Tyrol and from Italian fruits gave by fractional distn. 0.17–0.345% of *junene* (I), $C_{10}H_{16}$, b_{760} 164 6°, b_8 53–5°, α_D^{20} (1 dm.) +19.6° to +20.1°, possessing strong diuretic properties; a soln. in Ac_2O gave a red coloration with H_2SO_4. Reduction (H_2, Pd-$BaSO_4$, AcOH) of I gave *dihydrojunene*, $C_{10}H_{18}$, b_{760} 170°, b_8 58–61°, α_D^{20} (5 cm.) −6.5°. With HCl in AcOH I gave an additive product, b_8 76 86°, α_D^{20} −0.3°, and no cryst. products with Br, NOCl or HI, and did not react with BzO_2H. It is probably a cyclopentene deriv. similar to but not identical with the chamene of Kafuku, *et al.* (*C. A.* **25**, 2424). The juniper oils contained α-pinene, camphene and cadinene and, from the consts. of the terpene fraction, 5–15% of I. B. C. P. A.

Stabilization of hydrogen peroxide. Karl Höll. *Deut. Apoth.-Ztg.* **54**, 946(1939).—Expts. are reported which show the keeping qualities of 7.5% H_2O_2 with and without the addn. of stabilizers like BzOH, acetanilide and nipagin over a period of 2 yrs. With addn. of 0.1% of nipagin to 7.3% H_2O_2, e. g., there was a diminution in activity of only 0.2% during the 2-yr. period. W. O. E.

Production of stable solutions of calcium gluconate. J. Pfirschke and G. Peukert. *Deut. Apoth.-Ztg.* **54**, 992 (1939).—The production of such solns. in highly concd. supersatd. form is readily effected by addn. of min. amts. of Ca *d*-glucoheptonate. W. O. E.

Synthetic fat acids, in the place of oleic acid, for the preparation of Vasolimentum Erg. B. 5. Richard Holdermann. *Deut. Apoth.-Ztg.* **54**, 1091–2(1939). W. O. E.

Pharmaceutical coloring agents—substitute for Bordeaux B. C. L. M. Brown. *Quart. J. Pharm. Pharmacol.* **12**, 332–46(1939).—Sixteen dyestuffs were examd. for their suitability for coloring pharmaceuticals, and the effects of acid, alkali, salt concn., heavy metals and alkaloids were studied. Six dyestuffs were selected and the effects of oxidizing and reducing systems detd. Also their characteristic color reactions with concd. H_2SO_4 and their relative tinctorial values were detd. Their suitability for use in those prepns. of the National Health Insurance Formulary and the Brit. Pharmaceutical Codex which are artificially colored were examd., and suggestions offered. The keeping properties of Liquor Azorubri were investigated and an alternative formula was suggested. It has been shown that the dyes can be extd. from acid aq. solns. (and from acidified pharmaceuticals) by AmOH, and a scheme of analysis, by means of which the dyestuff can be identified, has been prepd. No satisfactory method was found for the estn. of dyestuffs in pharmaceuticals. W. O. E.

Absorption spectrophotometry in pharmaceutical analysis. I. Estrogenic preparations. W. F. Elvidge. *Quart. J. Pharm. Pharmacol.* **12**, 347–60(1939).—Preliminary results are presented on attempts to use spectrometric absorption methods in the routine control of tablets and ampoules of certain estrogenic compds. The results are promising, particularly in those cases where the hormone can be sepd. from the diluent, and it is intended to pursue this subject further, and to obtain more data. Curves are given for diethylstilbestrol (I), and its dipropionate, hexestrol(dihydro-I), estradiol monobenzoate and progesterone, together with the numerical values of their extinction coeffs. Tentative values have been assumed, which may be modified when more samples are examd. W. O. E.

Natural and artificial soft paraffins. Harry Brindle. *Quart. J. Pharm. Pharmacol.* **12**, 361–79(1939).—A simple test is proposed to distinguish between "natural" and "artificial" soft paraffins. The test consists in detg. the deposition temp., or soln. temp., of a soln. of the soft paraffin in a mixt. of glacial AcOH and CCl_4. The vols. of cryst. deposit, if any, and of the upper oily layer which seps., are also detd. Freedom from adulteration with liquid paraffin and hard paraffin is indicated by: (1) a high soln. temp., (2) a low vol. of cryst. deposit and (3) a considerable vol. of sepd. upper oily layer. W. O. E.

Nonstaining iodine ointment. J. C. Penman. *Quart. J. Pharm. Pharmacol.* **12**, 380–91(1939).— Large variations in results are obtained in the assay of com. samples of nonstaining I ointment. It is suggested that the Brit. Pharmaceutical Codex adopt a standard for total I content of not less than 4%. During the action of I alone on fatty oils, partial hydrolysis of the glycerides occurs. In the presence of I the glycerides of the unsatd. acids form pungent-smelling substances. A resin-like sticky sludge occurs when undissolved I is kept in contact with the fatty oils and with oleic acid. Iodine dissolved in fatty oils does not deposit a resin-like sludge. Alternative methods for the prepn. of nonstaining I ointment are given. It is indicated that the effect of heat upon the compounded ointment is to produce resin-like deposits. Fourteen references. W. O. E.

Stability of solutions of adrenaline hydrochloride. H. R. Rowlinson and S. W. F. Underhill. *Quart. J. Pharm. Pharmacol.* **12**, 392–8(1939).—Liquor adrenalinae hydrochloridi Brit. Pharm. retains its full potency for 16 months when stored under CO_2 at lab. temp. At 37.5° about half the potency was lost in 8 months. The addn of 0.5% Na metabisulfite or the substitution of HCl by SO_2 in the prepn. has little influence on the maintenance or loss of potency under these conditions of storage, but preserves the color of the soln. for a longer period. The color of a soln. of adrenaline-HCl is not an indication of its potency. Clear, colorless solns. lost 50% of their potency, while colored solns. may retain their full activity. The addn. of 0.1% of Na metabisulfite improves the keeping qualities of Liquor adrenalinae hydrochloridi Brit. Pharm. Eight references. W. O. E.

Rapid colorimetric assay of belladonna and stramonium, including their preparations. Noel L. Allport and Ewart S. Wilson. *Quart. J. Pharm. Pharmacol.* **12**, 399–408 (1939).—Morin's adaptation of Vitali's color test for solanaceous alkaloids has been modified in order to make it quant., and it is shown that, provided the alkaloid is first dissolved in dil. AcOH, the intensity of the color produced by the test is a function of the quantity of alkaloid present. By use of the Lovibond tintometer the color test was utilized for the development of a rapid alkaloidal assay of belladonna leaf, belladonna root, stramonium leaf

and their galenical prepns. Essentially, the method consists in the $CHCl_3$ extn. of a small quantity of the drug (or the prepn. previously absorbed on sawdust), agitation of the percolate with dil. AcOH soln. and detn. of the alkaloidal concn. in the sepd. acid aq. layer by means of the color test. An alkaloidal assay can be completed within an hr., or less, and the results compare favorably with those obtained by the official methods. W. O. E.

Occurrence of free vitamin A alcohol in fish livers. Thomas H. Mead. *Quart. J. Pharm. Pharmacol.* **12**, 409-12(1939).—It would appear that a small proportion of free vitamin A is present in the oil extd. from the fresh livers in spite of the attempt to reduce hydrolysis after the death of the fish. Seven references. W. O. E. 2

Assay of some mercurial ointments. G. J. W. Ferrey. *Quart. J. Pharm. Pharmacol.* **12**, 413-19(1939); cf. *C. A.* **33**, 1092[1].—Methods are developed for the assay of 4 mercurial ointments; the principles of reduction of the Hg compd. present to metal, and amalgamation with Zn dust or filings are used. The value of ethylene glycol monoethyl ether as a menstruum for sapon. in the assay of mercurial ointments contg. paraffins is shown. Six references. W. O. E. 3

Extraction process for the assay of phenol ointment. R. Maxwell Savage. *Quart. J. Pharm. Pharmacol.* **12**, 420-2(1939).—The extn. by dil. acid of phenol from its soln. in light petroleum was studied. A method of assay for phenol ointment is described. W. O. E. 4

Tannic acid gauze. R. Maxwell Savage and W. P. Chambers. *Quart. J. Pharm. Pharmacol.* **12**, 423-37(1939).—Methods of analyzing tannic acid solns. are discussed and certain suggestions offered. Tannic acid gauzes are found to be stable materials over 27 months' storage, no definite deterioration having been noted. Adsorption of tannic acid occurs, but is about equal to that which occurs with plain gauze soaked in fresh tannic acid soln. The conditions in compresses were studied. Apparent increases in gallic acid are traced mainly to differential adsorption and not to hydrolysis. Methods of detg. the total amt. of tannic acid in gauze are developed. Nine references. W. O. E. 5

Alkaloidal assay of lobelia and its preparations. H. A. Caulkin. *Quart. J. Pharm. Pharmacol.* **12**, 438-45(1939).—In the case of tinctures, acidify 50 ml. with 1 ml. dil. AcOH, add 25 ml. distd. H_2O and evap. in a porcelain basin to about 20 ml. Filter through a small funnel plugged with cotton wool into a separator, wash the residue in the basin with successive small quantities of H_2O acidulated with AcOH until all the alkaloids are removed. Render the liquid alk. with dil. NH_4OH and ext. with successive quantities of $CHCl_3$ until free from alkaloids, washing each quantity of $CHCl_3$ with the same 5 ml. of distd. H_2O. Ext. the $CHCl_3$ soln. of the alkaloids with 2% H_2SO_4 until the acid liquid ceases to give any reaction with Mayer's reagent, wash the mixed acid liquid once with 5 ml. of $CHCl_3$ and the $CHCl_3$ with 5 ml. of 0.1 *N* H_2SO_4 which is added to the main acid soln. Make the acid liquids alk. with dil. NH_4OH and ext. with successive quantities of $CHCl_3$, each portion of $CHCl_3$ being washed with the same 5 ml. of H_2O. Distil off the $CHCl_3$ until about 2 ml. remains, add 5 ml. abs. EtOH and evap. to dryness at a low temp. Make 2 further addns. each of 2 ml. abs. EtOH and evap. to dryness after each addn. Dry finally at 80°. Det. the amt. of alkaloid in the residue (1) by addn. of an excess of 0.02 *N* H_2SO_4 and titrating the excess acid with 0.02 *N* NaOH; (2) by converting the alkaloids into their HCl salts and detg. their Cl content by the addn. of 0.1 *N* $AgNO_3$ in excess and titrating with 0.1 *N* NH_4CNS; (3) by dissolving the alkaloids in dil. HCl and pptg. with silicotungstic acid. Results obtained by this procedure are reported. Eight references. W. O. E. 6

Stabilization of hydrogen peroxide solutions for pharmaceutical purposes. S. M. Tritton. *Quart. J. Pharm. Pharmacol.* **12**, 446-50(1939).—It is shown that the addn. of certain substances like acetanilide, phenazone, BzOH, thiourea, urea and hexamine tends to inhibit the decompn. of H_2O_2 by catalase. W. O. E. 7

Chemical assay of powdered ergot. Cyril Daglish and Frank Wokes. *Quart. J. Pharm. Pharmacol.* **12**, 451-67 (1939).—The Pharmacopeia Lab. method (employing a single 5-hr. extn.) does not remove all the alkaloid, even if the amt. of NH_3 is increased or dil. NH_3 is used, although this factor certainly does influence the results. The Brit. Pharmacopeia, 1932, method (shaking for $^1/_2$ hr. at room temp.) also failed to remove all the alkaloid from any of 6 samples examd. No clear evidence was obtained that the efficiency of the Brit. Pharmacopeia, 1932, method depended on the alkaloidal content of the ergot. The efficiency of Hampshire and Page's method (cf. *C. A.* **32**, 6002[6]), on the other hand, was definitely higher with low-potency ergots, in which it exceeded the efficiency of the Pharmacopeial method. A new method is described of assaying powd. ergot by shaking at room temp. with Ac-Me and NH_3 for half an hr.; it shows an av. efficiency of 93%. Seven references. W. O. E. 8

Review of analyses of drugs taken under the adulteration acts. J. F. Liverseege. *Quart. J. Pharm. Pharmacol.* **12**, 468-77(1939).—12 references. W. O. E. 9

Preparation of tablet triturates for use in hypodermic injections. G. W. G. Smithers. *Quart. J. Pharm. Pharmacol.* **12**, 478-88(1939).—Details of the prepn. of certain types of tablet triturates commonly in demand are described, together with the variations observed in the properties of such triturates when proportion and strength of alc., temp. of drying and quantity and nature of the active medicament vary. Four references. W. O. E.

Disintegration of tablets. C. L. M. Brown. *Quart. J. Pharm. Pharmacol.* **12**, 489-500(1939).—The present position respecting the standardization of tablets and the methods used by various workers to det. the disintegration of tablets was outlined. A new form of app. for testing tablets was described and details were given of expts. performed with it: the effects of compression and of 3 different ingredients (potato starch, gelonide and MgO_2) were shown, the results of an examn. of a no. of com. tablets were given and the effect upon disintegration of medicaments exhibited in "granular" form was shown. Three new terms applied to tablets—dry breaking wt., wet breaking wt., and disintegration ratio—were introduced and fully described. Purely as a guide to other workers tentative values were assigned to each of the 3 terms. Ten references. W. O. E.

Preparation of compressed tablets. I. Measurement of the rate of disintegration of compressed tablets. H. Berry. *Quart. J. Pharm. Pharmacol.* **12**, 501-10(1939). A method of measuring the rate of disintegration of compressed tablets has been suggested. The factors affecting the rate of the disintegration of compressed tablets have been investigated. W. O. E.

Estimation of small quantities of arsanilic acid in tryparsamide. C. A. MacDonald and J. G. Reynolds. *Quart. J. Pharm. Pharmacol* **12**, 534-40(1939).—A method is given for the estn. of small quantities of arsanilic acid in tryparsamide. The Pharmacopeial limit test for arsanilic acid in tryparsamide is satisfactory provided the sample contains mere traces of arsanilic acid. When a sample of tryparsamide contains more than traces of arsanilic acid, it is not possible by the Pharmacopeial test alone, to det. whether the sample may be said to satisfy the requirements of the Pharmacopeia or to be very much over the limit. W. O. E.

Riboflavin in liver extract. G. E. Shaw. *Quart. J. Pharm. Pharmacol.* **12**, 541-9(1939).—By careful heat-treatment an aq. liver ext. can be prepd. which, although it contains riboflavin, is nonfluorescent. A plain aq. ext. of liver at about pH 5.6 when boiled for about 30 sec. forms a ppt., and the clear yellow fluorescent filtrate, when extd. under certain conditions with benzyl alc., yield fluorescent material. It would not be expected that boiling for 30 sec. at pH 5.6 would split off phosphate from a nucleotide, but a polynucleotide might be broken down into simpler nucleotides. Where the riboflavin is in the form of a polynucleotide, especially when one of the constituent nucleotides is adenine, it is insol. in benzyl alc. Similarly, when the complex is conjugated with a protein, it is still insol. When the vitamin is in the form of a

nucleotide, or as its mononucleotide it is sol. in benzyl alc. A method has been described for the estn. of riboflavin in com. liver exts. The instability of riboflavin to HNO_3 has been shown. The form in which riboflavin exists in com. liver exts. has been discussed. Twenty-one references. W. O. E.

Preparation of solutions of gum acacia for intravenous injection. H. Gartside. *Quart. J. Pharm. Pharmacol.* 12, 550-62(1939).—Attention is directed to the quality of gum acacia used for the prepn. of a soln. for intravenous injection. A satisfactory method is described for the prepn. of a 4-fold concd. soln. and a 6% soln. of acacia-saline, together with a note on acacia-saline with dextrose. It is shown that the natural acidity of the soln. can be neutralized to an optimum pH, but neutralization beyond this point results only in the discoloration of the soln. When tested physiologically, on rabbits or mice, the solns. were satisfactory. W. O. E.

Easton's sirup—examination of the changes occurring during storage. W. T. Wing. *Quart. J. Pharm. Pharmacol.* 12, 563-72(1939).—The following formula is suggested as an improvement over the older prepn.: Fe 8.6 g., H_3PO_4 35.0 ml., strychnine-HCl 0.3 g., quinine-HCl 13.3 g., dil. HCl 50.0 ml., sirup 660.0 ml., glycerol 140.0 ml. and distd. H_2O to 1000.0 mls. The mode of compounding is given in detail. Ten references. W. O. E.

Preservation of pharmacopeial paraldehyde. James S. Toal. *Quart. J. Pharm. Pharmacol.* 12, 573-9(1939).—Expts. were carried out to show that freshly prepd. paraldehyde decomps. on storage. It has been demonstrated that the addn. of small amts. of phenolic compds. retards decompn. W. O. E.

Heart poisons. K. Brunner. *Pharm. Zentralhalle* 80, 605-13, 619-21, 630-3(1939).—An enumeration of the more important members of this group. 31 references. W. O. E.

Detection of codeine in papaverine hydrochloride. A. Iermstad and B. Fretheim. *Pharm. Zentralhalle* 80, 629-30(1939).—Dissolve 0.05 g. of the sample and 0.02 g. sulfanilic acid in 1 cc. 0.1 *N*-HCl and 0.5 cc. 1% $NaNO_2$ soln. After 1 min. add 2 cc. 4.0 *N* NaOH soln. Heat the mixt. 5 min. in the water bath in a test tube covered with a watch glass; no reddening of the liquid should result. W. O. E.

The more recent investigational results on ergot alkaloids and their relations to pharmaceutical practice. Benno Schwenke. *Pharm. Zentralhalle* 80, 641-6, 653-8 (1939). W. O. E.

Quirinus oil from Tegern Sea. Heinrich Huber. *Süddeut. Apoth.-Ztg.* 79, 749-50(1939).—A brief account is given of the natural oil emanating from about the Tegern Sea and said to possess curative properties. W. O. E.

Application of active alumina in pharmacy and cosmetics. Walter Meyer. *Süddeut. Apoth.-Ztg.* 79, 773-6, 781-8 (1939). W. O. E.

Assay of a sample of opium ninety years old. With some remarks on the history of morphinometric assay. Horatio C. Wood and Arthur Osol. *Am. J. Pharm.* 111, 380-4(1939).—From the review of the early literature on opium assay the authors conclude that the method of Guillermond (*J. Pharmacie*, 14, 463 (1828,) was employed when the sample of opium was assayed originally. As this process gives too high results it seems probable that the original morphine content (supposedly 10%) was not materially lower than the 9.72% which the authors obtained 90 years later. Results therefore seem to indicate that the morphine content of opium does not alter greatly under ordinary methods of storage. W. G. G.

Preservatives for nasal jellies and ophthalmic solutions. Louis Gershenfeld and David Tomkin. *Am. J. Pharm.* 111, 385-99(1939).—Nasal jellies: The following preservatives displayed either bacteriostatic or bactericidal properties, did not attack the collapsible tubes, and did not possess an objectionable color, odor, or appearance after a period of 4½ months: 0.05% ethyl hydroxybenzoate of sodium, 0.03% propyl hydroxybenzoate of sodium (not bactericidal), 0.1% hydroxyquinoline sulfate, 0.2% HCHO, 1:3000 hexylresorcinol, 0.01% azochloramid, 0.01% 2-naphthol, 0.01% merthiolate, 0.02% butoben not bactericidal, 0.002% phenylmercuric acetate, 0.002% phenylmercuric nitrate, 0.5% chlorobutanol. Ophthalmic solns.: chlorobutanol (0.5%), chlorothymol (0.01%), merthiolate (0.01%), phenylmercuric acetate (0.002%), and phenylmercuric nitrate (0.002%) displayed bactericidal power after 6 days. The following displayed bactericidal properties after 20 days: 0.05% ethyl hydroxybenzoate of sodium, 0.05% propyl hydroxybenzoate of sodium, 0.5% sodium benzoate, 0.02% butoben, 0.05% hydroxyquinoline sulfate, 0.01% mercurophen (ppts.) and 0.1% collargolum. Methyl hydroxybenzoate of sodium (0.15%), sodium benzoate (0.1%), acriflavine (0.01%), synthetic camphor (0.1%), phenyl hydroxy mercuric chloride (satd. soln.), and Cu sulfate (0.01%) were bactericidal after 35 days. W. G. Gaessler

Colorimetric silicomolybdic acid method for determining small quantities of nicotine. G. L. Sutherland, R. P. Daroga and A. G. Pollard. *J. Soc. Chem. Ind.* 58, 284-8 (1939); cf. Hofmann, *C. A.* 27, 3288.—The following Hoffman reagents were used: (1) silicomolybdic acid: 14.4 g. of MoO_3 is dissolved in *N* NaOH by warming. A soln. of Na_2SiO_3 contg. 0.7 g. SiO_2 is added, followed by 10% HCl which is stirred in, in small portions, until the soln. becomes green (about 200 ml.). The soln. is dild. to 900 ml. with H_2O and placed on a boiling water bath for 3 hrs. After standing for 24 hrs. at room temp., excess SiO_2 is filtered off and the filtrate is dild. to 1 l. (2) Wash liquid: 10% NaCl in 0.5% HCl. (3) Reducing soln.: 1 g. of glycine is dissolved in 15 ml. of 20% aq. Na_2S soln.; 5 ml. of NH_4OH (sp. gr. 0.880) is added in small portions while stirring, and the soln. is dild. to 100 ml. The detn. is conducted as follows: Add 2 ml. of reagent (1) to a 100-ml. beaker contg. the nicotine in 15 ml. of 1% HCl. Warm and shake the beaker until the ppt. dissolves or is obtained in a dense compact form if there is too much to dissolve readily. If the ppt. appears to be large, add 1 ml. more of reagent. After standing at least 2 hrs. at room temp., collect the ppt. on a disk of No. 42 Whatman paper in a small (No. 00) Gooch crucible. Wash the beaker and ppt. with successive quantities of 1.0, 0.5 and 0.5 ml. of the wash liquid. Empty and wash the filter flask. Pipet 2-3 ml. of the reducing soln. into the beaker and dissolve any residual ppt. present. Pour this soln. carefully into the Gooch crucible and stir the contents of the crucible with a glass rod. Then suck the soln. into the filter flask, followed by the washings of the beaker and filter. Transfer the liquid and washings to a 50-ml. graduated flask and dil. to the mark. Place the flask in a water bath at 45° for 25 min. and then match the color against permanent glass standards in a Tintometer or against special glass standards in the disk of a B. D. H. Lovibond nesslerizer. Colors of low intensity (less than 0.5 mg. of nicotine) were fully developed in 20 min., while deeper colors (greater than 1 mg. of nicotine) required 30 min. at 45°. Det. nicotine in *soil* in the following manner: Add 3 g. of CaO and 20 g. of NaCl to a suspension of soil contg. 1.5 mg. of nicotine in 200 ml. of water. Pass a current of steam through the heated suspension and collect 250 ml. of distillate in a receiver contg. 10 ml. of 1% HCl (a special app. for the steam distn. is described by Higgins, *et al.*, *C. A.* 33, 9200[4]). Evap. the distillate to 5–10 ml. and make up to approx. 15 ml. with 1% HCl. Ppt. the nicotine with the silicomolybdic acid reagent and proceed as directed above. The amt. of nicotine recovered from the soil was ± 2% of the quantity added. L. W. G.

South African fish products. I. Liver oils from the stockfish or hake (Merluccius capensis, Cast), and from the kingklip or cape ling (Genypterus capensis, Smith). C. J. Molteno and W. S. Rapson. *J. Soc. Chem. Ind.* 58, 297-8(1939); cf. *C. A.* 33, 8114[9].—The liver oils from the stockfish (I) are light yellow in color and have acid nos. less than 0.4. About 5% of stearin seps. from the oil on chilling. Seasonal variations in quality of the oil are very small although there is a marked increase in yield from the livers during the summer months, with a corresponding increase in I no. and a decrease in vitamin A potency. The following data are given for fish of

different sizes: av. wt. 12–16, 8–14, 1–2 lb.; av. wt. of livers 430, 286, 9.5 g.; oil in livers 36, 42, 11%; I no. of oil (Wijs) 126, 131, —; vitamin A in oil 1.1, 0.31, 0.30%, resp. Kingklip liver oils (II) are similar in color to I but contain relatively little stearin. Seasonal variations in yield and quality resemble those shown by I. During spring and summer, however, there is a much greater decrease in liver-oil content in the case of II but the vitamin A content of the oil is not affected. The oils from the larger kingklip are of considerable com. value since they are remarkably free from any fishy or unpleasant odors, contain very little stearin and compare favorably with halibut-liver oils in vitamin A potency. L. Wilson Greene

Chemical microscopy of essential oils. III. L. Wilson Greene. *Perfumery Essent. Oil Record* **30**, 309–16(1939); cf. *C. A.* **33**, 3068⁹.—The chemical principles and methods of essential oil microscopy are discussed. Crystn. reaction products, useful for characterizing these products, were obtained with the following oils and reagents: bergamot oil with satd. solns. of NaOH in EtOH and BuOH; bitter almond oil and benzaldehyde with phenylhydrazine (I), $NaHSO_3$ soln. (II), alk. $KMnO_4$ soln. and semicarbazide hydrochloride soln.; caraway oil and carvone with I; cassia oil and cinnamon bark oil with I, II and a 60% aq. Na phenate soln. (III); catnip oil with I; cumin oil with I and III; fennel oil and dog-fennel oil with I; and wintergreen oil, sweet birch oil and Me salicylate with III and with satd. solns. of KOH in MeOH and PrOH. A list of 131 different oils giving neg. results with I is presented. Crystn. reaction products are illustrated by 13 sketches. 11 references. L. Wilson Greene

Analysis of pills containing plasmocid and atebrin. N. S. Goryunova. *Farmatsiya* **1938**, No. 1–2, 4–9; *Khim. Referat. Zhur.* 2, No. 2, 85–6(1939).—The detn. is based on the ability of the insol. plasmocid and the sol. atebrin, when decompd. with alkali, to yield bases which are easily sol. in org. solvents. In addn., atebrin is sepd. from the aq. soln. with KI as a double salt. In the detn. of plasmocid its base is sepd., dissolved in an org. solvent (ether) and titrated with acid (1 cc. of 0.1 *N* HCl corresponds to 0.0287 g. of the plasmocid base). Atebrin can be titrated directly with a base in the presence of phenolphthalein (1 cc. of 0.1 *N* HCl corresponds to 0.01995 g. of the atebrin base). The sepn. of the substances from the mixt. of both compds. is performed after the sepn. and the extn. of the bases (the presence of the pill mass complicates the filtration considerably). The bases are transformed into HCl salts and the atebrin is sepd. with KI in the form of the double salt.

W. R. Henn

Evaluation of peppermint water from its surface tension. N. A. Izmaĭlov and A. G. Shvartsman. *Farmatsiya* **1938**, No. 1–2, 17; *Khim. Referat. Zhur.* 2, No. 3, 83 (1939).—The existing methods for the evaluation of aromatic waters give no indication if peppermint water prepns. comply with the pharmaceutical standards. The dependence of the surface tension of aq. peppermint solns. on the concn. of oil (calcd. to the total menthol) was detd. Addn. of NaCl increased the accuracy in the limits of the application of the detn. The error did not exceed ±3%. The vessel and the salt must be checked for the absence of admixts. of surface-active substances.

W. R. Henn

A drop-chromatographic method of analysis and its utilization in pharmacy. I. N. A. Izmaĭlov and M. S. Shraĭber. *Farmatsiya* **1938**, No. 3, 1–7; *Khim. Referat. Zhur.* 2, No. 2, 90(1939).—A drop-chromatographic method is proposed which permits observing the distribution of the substance in different zones in a drop of the substance placed on a flat layer of an adsorbent (CaO, MgO, Al_2O_3, etc.) 2 mm. thick on an object glass. The ultrachromatogram consists of concentric circular zones which are visible (owing to fluorescence) in the light of a Hg quartz lamp. The ultrachromatogram is developed with several drops of the solvent. Comparative investigations of 2 methods (performed on infusions of belladonna and of digitalin) gave full agreements of the chromatograms and the ultrachromatograms. This confirms the suitability of the drop-chromatographic method for a preliminary testing of the properties of the adsorbent and of the method of developing. The method can also be used for qual. evaluation and identification of the galenical preparations. In the last case some difficulties are caused by the indefinite color. A detn. of an exact color nomenclature of the colored zones for the drop-chromatographic analysis is contemplated. W. R. Henn

The determination of the quality of belladonna. N. V. Kuznetsov. *Farmatsiya i Farmakol.* **1938**, No. 3, 21; *Khim. Referat. Zhur.* 2, No. 3, 84(1939).—From a bush of a 2-year-old belladonna plant take 2 furcate leaves, air-dry them, take off a part of the middle vein between the 2nd and 3rd primary nerves, sep. the removed part from the parenchyma, treat it on a watch glass with 0.2 cc. of a 0.62 *N* H_2SO_4 soln. from a microburet, cover with a second watch glass and infuse for 50 min. Add a drop of Maier's reagent. The formation of a ppt. or of a turbidity shows a high quality of the leaves. A turbidity corresponds to 0.9–1% of alkaloids and a ppt. corresponds to a higher content. W. R. Henn

Microchemical reactions of barbital. E. E. Rozhdestvenskaya. *Farmatsiya* **1938**, No. 4, 1–6; *Khim. Referat. Zhur.* 2, No. 3, 83–4(1939).—All methods of analysis are confined to the extn. with ethyl acetate. Barbital is identified by microsublimation and microscopic investigation of the sublimate. Ammoniacal soln. of $AgNO_3$ is the most sensitive and the most characteristic reagent. Its sensitivity was 0.003 mg. in a drop. Salicylic and benzoic acids give ppts. of another kind. Phenobarbital, phenacetin and caffeine give no cryst. ppts. Reactions in basic solns. with an ammoniacal soln. of $CuSO_4$ also is characteristic, but the sensitivity is 0.06 mg. in a drop. Reaction with a 3% $CuSO_4$ soln. in the presence of pyridine (Zwikker's reagent) has a sensitivity of 0.02 mg. in a drop.

W. R. Henn

Determination of essential oil in alcoholic solutions. S. I. Spiridonova. *Novosti Nauki i Tekh. Efirno-Maslichnoĭ Prom.* **1938**, No. 3–4, 61–5; *Khim. Referat. Zhur.* 2, No. 3, 86(1939).—Prep. several dilns. of the alc. soln. and titrate 1 cc. of each with water from a 2-cc. microburet until the first permanent slight turbidity appears. Take the mean of the results of 3 titrations as the true value. Plot the vol. of water for the titration of 1 cc. of each soln. against the ratio of the vol. of alc. used for the diln. to the vol. of the initial soln. for each concn.

W. R. Henn

Some impressions of Finland and Finnish pharmacy. O. Ströh Andersen. *Arch. Pharm. Chem.* **46**, 630–49 (1939). Otto Johnson

Newer methods in galenic pharmacy. J. Büchi. *Dansk Tids. Farm.* **13**, 205–31(1939).—A lecture given before the Danish Pharmaceutical Soc. Otto Johnson

Coloration in codeine solutions. Kai Rørbye. *Dansk Tidsk. Farm.* **13**, 261–72(1939)(German summary).—For the prepn. of solutio codeini spirituosa and syrupus codeicus that will remain colorless for an appreciable period it is recommended that the original codeine soln. be free of color and that the sugar sirup used contain only small amts. of invert sugar. Otto Johnson

Pharmacognostic study of the leaves of Hammamelis virginiana L. Yutake Yosida. *J. Pharm. Soc. Japan* **59**, 582–605(in German, 174–7)(1939). F. I. Nakamura

Content of free eugenol in oil of Parma violet flowers. Sébastien Sabetay and Lucien Trabaud. *Compt. rend.* **209**, 843–5(1939).—Examn. of oil of Parma violet flowers of the highest quality shows it to contain approx. 21% eugenol. A similar examn. of oil from mixed leaves of Parma and Victoria violets showed the presence of mere traces of eugenol. This difference is the chief cause of the difference in scents of the oils from the leaves and flowers (cf. Ruzicka, *C. A.* **32**, 6805⁶). C. A. Silberrad

Constituents of some Indian essential oils (Carter, *et al.*) **10.** Preserving oxidizable substances [essential oils] (Brit. pat. 508,442) **13.** Fat acids and glycerides of neem oil [medicinal properties] (Hilditch, Murti) **27.**

Substance for lowering the blood pressure. Ernst Wollheim. U. S. 2,175,334, Oct. 10. See Ger. 663,994 (*C. A.* **33**, 321[4]).

Crystallizing insulin. Melville Sahyun (to Frederick Stearns & Co.). U. S. 2,174,862, Oct. 3. A process of crystg. insulin involves prepg. an aq. soln. of insulin contg. a phosphate buffer, an org. solvent such as iso-PrOH, and $ZnCl_2$ or other sol. salt of Zn, Co, Ni or Cd, and contg. about 20–100 units of insulin per cc. of the soln., adjusting the pH of the soln. to about 6.8, heating to about 60°, sepg. the ppt. from mother liquor, gradually increasing the acidity of the mother liquor to about pH 6.0 and gradually lowering its temp. to about 4°, sepg. insulin crystals formed, increasing the acidity of the mother liquor to about pH 5.2, removing the ppt. thus formed and dissolving it in dil. H_2SO_4, adjusting the acidity of the last-named soln. to about pH 3.5, and removing the resulting ppt. Cf. *C. A.* **33**, 1446[9].

Alkylethylamines. Schering A.-G. Brit. 508,726, July 5, 1939. β- Di- and -tri-alkylethylamines contg. 11–18 C atoms are prepd. by reducing the corresponding nitriles or acid amides. The starting materials may be prepd. according to the processes of Brit. 393,055, 394,087 (*C. A.* **27**, 5755), and 469,921 (*C. A.* **32**, 729[6]). The products *possess therapeutic properties*. Among examples, (1) β,β,β-tributylethylamine is obtained by the hydrogenation of tributylacetonitrile in an autoclave with use of a Ni-kieselguhr catalyst, or by similar treatment of tributylacetamide in the presence of a Ni catalyst prepd. by reduction of pptd. basic Ni carbonate, and (2) dihexylacetonitrile is shaken with H in the presence of a Raney Ni catalyst prepd. by the process of U. S. 1,915,473 (*C. A.* **27**, 4361) to give β,β-dihexylethylamine.

Composition for treatment and prevention of mycotic and similar skin infections. Douglas T. Prehn. U. S. 2,175,780, Oct. 10. Salicylic acid 2–12, menthol 2–15, and camphor 3–15% are used with a vehicle such as alc.

Procaine butyrates as local anesthetics. Gerald F. Rorer (to Wm. H. Rorer, Inc.). U. S. 2,175,782, Oct. 10. A procaine butyrate is used in various mixts. suitable for swabing or injection, as in dental work.

Concentrates of vitamin G. Lela E. Booher and Lincoln T. Work. U. S. 2,175,014, Oct. 3. A process for the prepn. of a concentrate of vitamin G from aq. solns. thereof comprises adding an amt. of silicious adsorbent material whereby the greater part of the vitamin is adsorbed from the soln.; sepg. the silicious adsorbent from the body of the soln.; treating the silicious adsorbent with water, alc. or dil. HOAc at an elevated temp.; sepg. the solvent from the adsorbent at a temp. above that at which adsorption had taken place; prepg. an aq. soln. from the eluate by removing any nonaq. solvent which may be present; adding an amt. of adsorbent C to the soln. whereby the greater part of the vitamin is removed from the soln.; sepg. the C from the soln.; eluting vitamin G from the C with benzene-alc. and sepg. the benzene-alc. from the C at an elevated temp.; and evapg. the benzene-alc. from the so-produced soln.

Preparing purified testosterone. Ernst Laqueur, Karoly G. David, Elizabeth Dingemanse and Janos Freud (to Ciba Pharmaceutical Products, Inc.). U. S. 2,175,963, Oct. 10. A soln. contg. testosterone in an org. solvent (preferably acetone of 60% concn.) which is inert to H_2SO_4 is extd. with 55–75% H_2SO_4, and the H_2SO_4 layer formed is dild. with water to a concn. not higher than 40% H_2SO_4, the soln. is extd. with a solvent immiscible with water, such as ether, the org. solvent is removed by evapn., and the residue is subjected to distn. in a high vacuum and the distillate is collected. Various details and modifications of procedure are given, and a cryst. product is obtained, m. 154–154.5° after several recrystns. from dil. acetone.

Separation of phenols from solvents such as those of germinal gland hormone solutions. Erwin Schwenk and Bradley Whitman (to Schering Corp.). U. S. 2,174,532, Oct. 3. Impure solns. such as those of hormones are treated under substantially anhyd. conditions with an excess of an inorg. alk. compd. reacting with phenolic hydroxyls to effect pptn. of the phenols, and pptd. phenolate material is sepd.

Purifying antibody compositions. Ivan A. Parfentjev (to Lederle Laboratories, Inc.). U. S. 2,175,090, Oct. 3. A method of purifying a soln. contg. antibodies assocd. with proteins involves adding a proteolytic enzyme such as pepsin, active in acid media, to the soln., adjusting the pH to about 3.0–3.2 and digesting the proteins without substantial destruction of the antibodies for about 2–6 hrs. after adding the enzyme, filtering and treating the filtrate with finely divided tri-Ca phosphate.

Germicidal alkylated halophenols. Lindley E. Mills (to Dow Chemical Co.). U. S. 2,176,010, Oct. 10. By the direct action of Cl or Br on alkyl phenols (heated to above the m. p. or in a solvent) or by other reactions such as: (1) the condensation of a halogenated phenol with an alkyl halide in the presence of a catalyst such as $ZnCl_2$ or $AlCl_3$; or, (2) hydrolysis of a di- or tri-halogenated alkyl-substituted benzene in the presence of a suitable catalyst, *e. g.*, Cu or Cu_2O; or, (3) diazotization of a halo-alkyl aniline and decompn. of the resulting product, germicidal compds. are produced such as: 2-chloro-4-*tert*-butylphenol, b_{3-4} about 85–6°; 2-bromo-4-*tert*-amylphenol, b_{6-7} 119–20°; 2,6-dibromo-4-*tert*-octylphenol, b_{3-6} 158–163°; 2-chloro-4-hexylphenol, b_{8-10} 143–6°; 2,6-dichloro-4-hexylphenol, b_8 154°; 2-bromo-4-octylphenol, b_{11} 172–3°; and 2,4-dibromo-6-octylphenol, m. 28° and b_7 190–2°. Details of the production of these compds. are given; and general mention is made of the similar production of other compds. such as 2-bromo-4-*sec*-butylphenol, 2,6-dichloro-6-isobutylphenol, 2,6-dibromo-4-*sec*-amylphenol, 2-chloro-4-*sec*-heptylphenol, 4-bromo-3-*sec*-butylphenol, and 2-chloro-6-*sec*-amylphenol. The products have a high germicidal action against *Staphylococcus aureus*, *E. typhi* and *B. typhosus*.

Bactericidal product. Meyer S. Glauser. U. S. 2,174,976, Oct. 3. A bactericidal product suitable for use on the skin is produced by heating equal amts. of *m*-dihydroxybenzene and gum camphor to the b. p. and continuing boiling for 5 min.

Cosmetic for preventing or reducing sunburn. Charles L. Parsons (50% to Henry C. Parker). U. S. 2,175,213, Oct. 10. A substantially flesh-colored, flaked, light-wt. metal powder such as dyed or pigmented Al is dispersed in a vehicle such as petrolatum, etc.

Detergents suitable for toilet use. Robert A. Duncan (to Procter & Gamble Co.). U. S. 2,175,285, Oct. 10. A detergent in bar form substantially free from soap contains predominantly a mixt. consisting of 5–60% of a satd. superglycerinated fat having at least 12 C atoms in the fat acid radical and not less than about 40% of a substantially solid water-sol. salt such as the Na salt of a compd. from the group consisting of the following, in all of which the alkyl radical contains more than 8 C atoms: sulfonated aliphatic alcs., sulfated aliphatic alcs., sulfonated aliphatic hydrocarbons, sulfated aliphatic hydrocarbons, fatty acid esters of hydroxyethane sulfonic acid, fatty acid amides of methylaminoethane sulfonic acid, fatty acid esters of dihydroxypropane sulfonic acid and alkyl ethers of dihydroxypropane sulfonic acid.

18—ACIDS, ALKALIES, SALTS AND OTHER HEAVY CHEMICALS

E. M. SYMMES

Automatic control and regulation in the production of sulfuric acid. K. F. Pavlov, E. G. Golubev and B. I. Arkhangel'skiĭ. *Avtomatika i Telemekhanika* **1938**, No. 1, 107–22; *Khim. Referat. Zhur.* **2**, No. 3, 88(1939).—By means of several examples, problems are illustrated which are encountered in the introduction of automatic control

and regulation of H_2SO_4 production. An automatic regulator for the dilu. of fuming H_2SO_4 to 98.5% is operated by measurement of the concn. of the acid by elec. resistance. W. R. Henn

Intensification of the tower sulfuric acid process. V. N. Shul'ts. *Wiss. Werke moskau. mendelejeff. chem.-tech. Inst.* **1938**, No. 3-4, 5-10; *Khim. Referat. Zhur.* **2**, No. 1, 74(1939); cf. *C. A.* **32**, 2295[3]; **33**, 1887[4].—The tower system consisted of 7 towers, 5 of which were formerly used as towers of the Glover and Gay-Lussac system. A yield of 77.5 kg./cu. m. was obtained, with an expenditure of HNO_3 of approx. 15 kg./ton of H_2SO_4. The process of H_2SO_4 formation was practically completed in the first 3 towers, which comprised 45% of the total vol. of the system. The first 2 towers served as denitrators at the same time, and absorption of the N oxides took place in the 3rd tower. This points to the possibility of combining (in definite limits) the production and the absorption parts of the tower system. W. R. Henn

Problems of the magnesium salts. N. S. Spiro. *Byull. Inst. Halurgii* **1938**, No. 1, 28-46; *Khim. Referat. Zhur.* **2**, No. 3, 98(1939).—Salt lakes are the purest, cheapest and most abundant sources of Mg. The solns. of Mg salts were electrolyzed, with diffusion diaphragms; a good yield was obtained, especially with a cathode, c. d. of 0.004-0.03 amp./sq. cm. A yield of 90-95% was obtained from the electrolysis of solns. contg. NaCl and $MgSO_4$. The ppt. contained fairly pure $Mg(OH)_2$, with admixts. of Mg(OH)Cl. A cycle was developed for the pptn. of Mg from solns. by means of NaOH, which was prepd. by electrolysis of NaCl and Na_2SO_4 from the solns. after the pptn. of Mg. In electrolysis of astrakanite contg. 150 g./l. of H_2SO_4, about 3.5-4.5 kw.-hrs. per kg. of $Mg(OH)_2$ was used. The method of extn. of $Mg(OH)_2$ from sea water according to (Ba, Ca)S + $MgCl_2$ + $2H_2O$ = (Ba, Ca)Cl_2 + $Mg(OH)_2$ + H_2S was investigated, and the method for obtaining MgO by liming was studied. Pptn. and filtration are facilitated by addn. of fine, unslaked lime, or by coagulation. The tanning exts. are good coagulants. W. R. Henn

Alkaline decomposition of kaolin for the recovery of alumina. W. D. Treadwell and H. Schneeberger. *Helv. Chim. Acta* **22**, 1048-58(1939).—A constitutional formula for kaolinite is given and discussed. Equations showing the assumed decompn. reactions are developed when mixts. of soda, $CaCO_3$ and kaolinite are heated. The decompn. of kaolinite depends upon temp. and time. The amt. of CO_2 evolved shows the extent of the reaction. Detns. were made of the proportion of immobilized alkali in the decompd. melt, and the quantities of SiO_2 going into soln. during the hydrolytic decompn. Most of the immobilized alkali in the melt can be recovered by hydrothermal decompn. The insol. residue had the compn. of a portland cement. A. W. King

Manufacture of alum, ferric sulfate and sodium aluminate. F. A. Abbiati. *J. New Engl. Water Works Assoc.* **53**, 247-54(1939).—Kalinite, alunite, pyrites schist, clay, kaolin and bauxite are basic materials for the manuf. of alum or Na aluminate, and the procedure is very similar save that H_2SO_4 is the dissolving medium with alum and an alk. soln. is used for Na aluminate. Ferrisul is the only ferric coagulant mentioned. D. K. French

Recent progress in the production of ammonium nitrate. Dino Maveri. *Chimica e industria* (Italy) **21**, 572-7(1939).—A description of the latest improvements made in the Fauser process (cf. Fauser, *C. A.* **25**, 3132; Pastonesi, *C. A.* **31**, 1963[6]). A. W. Contieri

The preparation of magnesium chloride flakes. G. S. Klebanov, V. M. Bukshtein and I. O. Evert. *Byull. Inst. Halurgii* **1938**, No. 7, 24-31; *Khim. Referat. Zhur.* **2**, No. 3, 98-9(1939).—In a lab. app., a boiler-iron cylinder of 0.5 sq. m. surface, cooled internally with water, revolves in a trough contg. fused $MgCl_2$. The crust of $MgCl_2$ is removed from the cylinder by a scraper. The optimum conditions for the prepn. of $MgCl_2$ flakes were: temp. of the melt in the trough 160-140°, velocity of cylinder 14 revolutions/min. The output was 0.3 ton/hr./sq. m. of cylinder surface and thickness of the flakes up to 1 mm. W. R. Henn

Natural soda in Siberia. A. S. Eliseev. *Byull. Inst. Halurgii* **1938**, No. 3, 42-59; *Khim. Referat. Zhur.* **2**, No. 3, 27(1939).—The soda-contg. lakes found in different parts of Siberia, which are of com. interest, are enumerated. Comparative characteristics and the tech., economic problems for their exploitation are discussed. W. R. Henn

Hydrolysis of titanium sulfate. B. A. Tsarev and Velikoslavinskiĭ. *Byull. Lako-Krasochnoĭ Prom.* **1938**, No. 6-7, 39-48; *Khim. Referat. Zhur.* **2**, No. 2, 107(1939).—As a result of preliminary expts. for the prepn. of TiO_2 by hydrolysis of dil. solns. of $Ti(SO_4)_2$ (about 120 g./l.), products of satisfactory filtering properties and color were obtained. Three methods were used: (1) a preliminary hydrolysis of 10-20% of the total vol. of soln. at a concn. of $Ti(SO_4)_2$ of 250 g./l. followed by addn. of dil. $Ti(SO_4)_2$ with a ratio (*R*) of active acid to TiO_2 of 2.45 or 2.58; (2) a preliminary hydrolysis of the $Ti(SO_4)_2$ soln. (*R* = 2.65) equal to 10-20% of the total vol., followed by the addn. of basic or neutral sulfate; (3) hydrolysis of the weak $Ti(SO_4)_2$ solns. with *R* = 2.44 in the presence of ZnO. The ZnO increased considerably the velocity of hydrolysis during the first hr., after which the velocity dropped sharply. Tests of direct hydrolysis of dil. basic or neutral solns. gave products of poor filtering properties. W. R. Henn

Helium, its sources, production and use. A. W. Trusty. *Refiner Natural Gasoline Mfr.* **18**, 325-6(1939). W. L. Benedict

Changes in the concentration of bromine in the saline waters of the lakes of the Kulundinskiĭ steppe. V. M. Bukshteĭn and N. I. Visyagin. *Byull. Inst. Halurgii* **1938**, No. 8, 48-54; *Khim. Referat. Zhur.* **2**, No. 3, 26-7(1939).—Lake Kulundinskoe contains 0.0052-0.0085%, Lake Kuchuk 0.026-0.0317%, Lake Bol'shoe Yarovoe 0.0263-0.0267%, Lake Burlinskoe 0.0547-0.0814% of Br. These values are slightly higher than values found by other investigators in 1932 and in 1935; this is attributed to evapn. of water from the lakes. Tabulated results show the change in Br concn. throughout the year for the main lakes of the Kulundinskiĭ steppe. W. R. Henn

A complete utilization of sea salt. N. S. Spiro. *Byull. Inst. Halurgii* **1938**, No. 3, 21-30; *Khim. Referat. Zhur.* **2**, No. 3, 96(1939).—The climatic conditions, transportation facilities and proximity of the Azov Sea are factors which permit a complete utilization of the strong salt solns. of waters found in Sivash for the production of NaCl, Br, MgO and its derivs. (carbonates, Sorel cement, etc.), $MgSO_4$ and Na_2SO_4. The technological scheme for the pptn. of Mg with lime is described. W. R. Henn

Industrial utilization of the Kulundinskiĭ salt deposits. V. M. Bukshteĭn. *Byull. Inst. Halurgii* **1938**, No. 7, 40-50; *Khim. Referat. Zhur.* **2**, No. 3, 26(1939).—Lake Kuchuk (160 sq. km.) is a reservoir of sulfates. About 600 million tons is contained in its saline waters and in its strata. Lake Bol'shoe Kulundinskoe (750 sq. km.) is less mineralized (7% of salts) and has no bottom deposits. The saline waters of Lake Kuchuk can be regarded as a (Na^+, Mg^{++}) $(Cl^-, SO_4^{--})H_2O$ system. Other ions are contained in very small amts. In winter, 380-640 thousand tons of mirabilite (150-60 kg./sq. m. of the saline water) is deposited. With increase of the temp. of the H_2O, the mirabilite dissolves. The d. of the saline water and its sulfate content increased steadily from 1930 to 1936 (the concn. of sulfate from 1.74 to 4%). The water remains satd. with NaCl; this might offer difficulties in the utilization of the Lake Kuchuk as a source of sulfates. Its water should be dild. with the water from the less mineralized Lake Bol'shoe Kulundinskoe. Soda, sulfates, Na_2S and a no. of other salts could be produced from it on a com. scale. Methods for the production of mirabilite are proposed. W. R. Henn

A technological scheme for the complete utilization of the Sivash saline water. R. A. Mandel. *Byull. Inst. Halurgii* **1938**, No. 5, 23-8; *Khim. Referat. Zhur.* **2**, No. 3, 96(1939).—Two different technological treatments of

the Sivash saline water are proposed consisting of a preliminary concn. (I) and of the diln. of the saline water (II). According to I, the saline water of western Sivash, of 6°Bé., contg. about 0.5% of $MgCl_2$ is evapd. in reservoirs to 13% $MgCl_2$ (a ppt. of NaCl is formed). After the sepn. of Br by blowing, the saline water is treated with a $CaCl_2$ soln. for the sepn. of SO_4^{--}. The gypsum residue is used for the manuf. of alabaster. The $MgCl_2$ soln. is partly passed into the reservoir for further evapn. and partly treated with slaked lime for the production of different grades of MgO or of $MgCO_3$. The $CaCl_2$ soln. (which remains after the pptn. of $Mg(OH)_2$) is evapd. and the sulfate pptd. from it. The part of the $MgCl_2$ soln. which was evapd. in the reservoir is used for the production of Sorel cement or of gypsum-Mg cement. In II the saline water of the southern reservoir of Sivash, of 12°Bé., is mixed with water from the Azov Sea in the ratio 1:3.43 to prevent the sepn. of gypsum in the following treatment. The dild. saline water is decarbonized with milk of lime and after sepn. of the carbonate and of Br, a ppt. of $Mg(OH)_2$ is obtained. W. R. Henn

Foam formation in natural salt solutions and its prevention. L. M. Zarudskiĭ and T. V. Korobochkina. *Byull. Inst. Halurgii* **1938**, No. 3, 13–20; *Khim. Referat. Zhur.* **2**, No. 3, 97–8(1939).—The formation of foam is caused by the simultaneous presence of carbonates, org. substances and mech. admixts. Their removal from solns. decreases considerably or overcomes completely formation of foam and increases simultaneously the surface tension. To remove foam-forming substances, chlorinated $Fe_2(SO_4)_3$ was added to the soln. until its presence could be detected in the filtrate by means of $K_4Fe(CN)_6$. A scheme for the lab. expts. is given. W. R. Henn

The concentration of hydrogen ions and the surface tension of natural salt solutions. L. M. Zarudskiĭ and T. V. Korobochkina. *Byull. Inst. Halurgii* **1938**, No. 6, 1–16; *Khim. Referat. Zhur.* **2**, No. 3, 7(1939).—A no. of curves are given of potentiometric titrations (with quinhydrone electrode) of the natural salt solns. (well water, Chusovskn and Beyuk-Shorskiĭ saline waters, etc.). All solns. investigated possessed considerable buffer properties, which were caused by the presence of salts of weak org. acids. The accuracy of the detns. was very low. Curves of parallel detns. varied greatly; this may be explained by the inconstancy of the compn. of the solns. The surface tensions in a no. of cases were greatly lowered (in spite of a large concn. of the salts) by the presence of org. compds. The characteristics of waters, of different depths and concns., depending on their chem. compn. and origin, are shown. Causes detg. their pH values (hydrolysis, equil. between CO_2 and the carbonates, etc.) are discussed. W. R. Henn

Problems and investigations of the Crimean salt-bearing lakes. V. E. Grushvitskiĭ. *Byull. Inst. Halurgii* **1938**, No. 2, 68–89; *Khim. Referat. Zhur.* **2**, No. 3, 96–7 (1939).—The Crimean lakes contain considerable amts. of Br. A method for the prepn. of fine NaCl was developed by salting out with a concd. salt soln. having a high content of $MgCl_2$. Up to 45% of the $MgSO_4$ content was obtained at 5° from the mother liquor (after the sepn. of NaCl). Conditions for the enriching and sepn. of $MgCl_2$ from the solns. and of its bleaching were investigated. Refining of crude Br, increase of its concn. and the technological production were studied. Conditions for sepn. of Na_2SO_4 (thenardite) were investigated; the contents of K in solns. and of Cl in $FeBr_3$ were detd. On the basis of the exptl. results obtained a project for the construction of the Perekop Br-producing plant was developed. W. R. Henn

Salt-bearing formations of the western slope of the Ural mountains as a base for the salt-working industry. P. I. Preobrazhenskiĭ. *Byull. Inst. Halurgii* **1938**, No. 1, 47–60; *Khim. Referat. Zhur.* **2**, No. 3, 25(1939).—The complex exploitation of the salt-bearing formations bounded by the western slope of the Ural mountains and the Kama and Volga rivers in the east is discussed. The presence of rich deposits of NaCl, sylvinite, carnallite (in Solikams, Berezniki, Usol'e and the Dedyukhin's mines), halite and salts richer in K_2SO_4, the content of Br in brines (up to 1500 mg./l. in Ust-Borovskiĭ) and of I (up to 120 mg./l. in Chusovskie Gorodki), and the presence of H_2S (up to 1000 mg./l.), and of borates, make possible the development of chem. industry in this region. The presence of petroleum (in Chusovskie Gorodki and in Ishimbaevo) and of natural gas, in conjunction with the water resources of the Kama and Volga rivers as a source of hydroelec. power, create exceptional conditions for the development of this region. W. R. Henn

Possible ways for the utilization of astrakanite. V. E. Grushvitskiĭ. *Byull. Inst. Halurgii* **1938**, No. 7, 9–23; *Khim. Referat. Zhur.* **2**, No. 3, 97(1939).—Astrakanite is found in considerable amts. in lakes near the Aral Sea. Essentially the same products (Na_2S and MgO) were obtained by the reduction of astrakanite with different gases (H_2, CH_4, CO) or with coal at high temp. Na_2S can be sepd. from MgO by lixiviating the melt with water. At optimum conditions (900–1000°) the duration of the process was 1–2 hrs. The amt. of reducing agent used was 0.1–0.7 tons per ton of astrakanite. A practically complete reduction of astrakanite was obtained when suitable reducing agents were used. A ppt. of Glauber's salt was obtained by freezing out the astrakanite transferred into soln. at −5, 0 and +5°. From a more concd. soln. a ppt. of $MgSO_4$ was formed, besides the Glauber's salt. The max. yield of Glauber's salt was 20–5% of the wt. of the soln. By isothermal evapn. of the mother liquor at 25° (after freezing out the Na_2SO_4) crystals of pure epsomite ($MgSO_4.7H_2O$) were obtained, at a $MgSO_4$ yield up to 65%. The disadvantage of this process is that Na_2SO_4 is sepd. in the form of Glauber's salt, from which the combined water must be removed. Pure Na_2SO_4 can be obtained only by salting it out with NaCl. By mixing astrakanite with NaCl in definite proportions, and keeping the mixt. in a thermostat at 55° until equil. is reached, a pure cryst. Na_2SO_4 was obtained, at a yield of SO_4^{--} up to 53% of its content in the soln. The velocity of soln., sp. gr. and mineralogical compn. of astrakanite were detd. W. R. Henn

Bleaching clays find increasing use. G. Austin Schroter. *Eng. Mining J.* **140**, 35–8, 40(Nov., 1939).—Improved demand has brought about some innovations in prospecting, mining and prepn. A discussion, including a classification of the bleaching clays, uses, geology, mining, prospecting, prepn. and milling. W. H. Boynton

Continuous activation of refining clays. M. L. Blagodarov. *Rabochiĭ Neftyanik* **1938**, No. 2, 21(1938); *Khim. Referat. Zhur.* **2**, No. 1, 91(1939); cf. *C. A.* **33**, 7500².—In lab. expts., 35% of H_2SO_4 (15–20% concn.) is passed together with finely ground clay to the top of a column. The temp. is maintained at 90°. The clay settles gradually and is removed from the bottom. H_2SO_4 is pressed out and 500% of water (on the wt. of clay) is used to wash the clay free from the acid and salts. Expts. on a semiproduction scale are contemplated. W. R. Henn

Revivifying bone char. A new method and apparatus. Edgar W. Rice. *Ind. Eng. Chem.* **31**, 1516–18(1939).—The app. comprises a rotating drum 4 ft. in diam. and 30 ft. long, with a firebrick combustion chamber at the lower end. Temp. is controlled by a thermocouple in the stream of outgoing material. The upper end is enclosed by a brick chamber with a flue to the stack and a duct to a recirculating fan. A mixt. of air and combustion gases cools the reactivated char and elevates it to the settling chamber. From this chamber the gases are led back to the combustion chamber. Oil is used as fuel; by the recirculation of gases, lower treating temp. is required. E. M. Symmes

Mech. properties and creep resistance of steels for use in equipment for NH_3 synthesis (Minkevich, Borzdyka) 9.

Sulfuric acid. Peter S. Gilchrist and James M. Rumple (to Chemical Construction Corp.). U. S. 2,174,739, Oct. 3. An arrangement of app. is described, and a method of simultaneously producing concd. H_2SO_4 from H_2S and concd. separated sludge acid which comprises burning

H_2S to form a moisture laden SO_2 gas, drying the SO_2 gas by a circulation of H_2SO_4, oxidizing the dried SO_2 to SO_3 in a contact H_2SO_4 process, introducing a portion of the dild. acid from the drying circuit together with sepd. sludge acid into a concentrator and subjecting the acid mixt. in the concentrator to heat produced as a result of the combustion of H_2S partially to conc. the acid mixt., introducing a portion of the partially concd. acid into the drying-acid circuit, absorbing the SO_3 produced by the contact process in an absorber circuit and introducing the remaining portion of the partially concd. acid from the concentrator into the absorption circuit to transform it into strong H_2SO_4.

Sulfur dioxide for producing sulfuric acid and ferric sulfate. Harmon E. Keyes. U. S. reissue 21,215, Sept. 26. A reissue of original patent No. 2,055,082 (*C. A.* **30**, 7793[4]).

Alkaline earth salts of alkyl sulfates. Anton J. Tulleners (to Shell Development Co.). U. S. 2,176,005, Oct. 10. At a temp. between 60° and 120°, a H_2SO_4-contg. alkyl acid sulfate of at least 7 C atoms is treated with a basic alk. earth metal compd. such as $Ca(OH)_2$ in the presence of sufficient acetone to cause pptn. of cryst. alk. earth metal sulfate. 3

Nitrates and chlorinated organic compounds. Mayor P. Fogler (to Solvay Process Co.). U. S. 2,174,574, Oct. 3. An arrangement of app. is described, and a process for the production of a nitrate such as $NaNO_3$ and a chlorinated org. compd. such as PhCl which involves: (1) causing HNO_3 to react with a metal chloride such as NaCl to form a nitrate and a gas contg. NOCl and Cl; (2) causing the NOCl to react with an org. compd. such as C_6H_6 to form a chlorinated compd. such as PhCl and a gas contg. N oxide and HCl; (3) passing the gas just mentioned in contact with an aq. liquor to absorb and sep. the HCl; (4) treating the N oxide with water and O to form HNO_3; and (5) utilizing the HNO_3 from step "4" to form addnl. metal nitrate. 4

Recovery of aluminum compounds from coal. Lucien Freling and Jules Dorten. U. S. 2,174,825, Oct. 3. A process for the recovery of Al compds. from coal, and the combustible waste materials obtained from the washing and screening of coal, involves mixing the raw material with milk of lime in a porportion of about 2.5% calcd. on the ash content of the raw material, burning the mixt. at temps. commonly attained in boiler furnaces, and treating the resulting ash with HCl at boiling temp. under atm. pressure. 6

Ammonium nitrate. Giacomo Fauser (to Montecatini, Società generale per l'industria mineraria ed agricola). U. S. reissue 21,217, Sept. 26. A reissue of original patent No. 1,987,552 (*C. A.* **29**, 1593[6]). 7

Calcium carbide. Frederick T. Snyder. U. S. 2,174,900, Oct. 3. An arrangement of app. is described, and a process for producing CaC_2, which, when carried out in an app. comprising an upright kiln communicating with an elec. furnace directly below, involves charging the kiln with mixed lime-producing material such as limestone or oyster shells and oil-contg. carbonaceous fuel such as wood or coal, and distg. the oil vapors from the fuel and converting the charge into lime and carbon by passing hot gases upwardly through the fuel, withdrawing the gases and vapors from the upper portion of the kiln, consuming a portion of the C content of the fuel in the kiln to effect distn. of the oil vapors by introducing O-contg. gases to the fuel bed at the lower portion of the kiln, discharging the lime and the remaining C direct to the elec. furnace without substantial heat loss, and heating the charge in the elec. furnace in a reducing atm. at a temp. sufficient to convert it into CaC_2, the process involving also stripping the oil vapors from the gases withdrawn from the kiln and cooling the residual gases, and controlling the temp. and partial pressure on the oil vapors in the distn. zone of the kiln by returning a portion, at least, of the cooled residual gases to the kiln at a point intermediate the zone at which the O-contg. gases are introduced to the kiln and the zone at which the oil-laden gases are withdrawn from the kiln. 1 2

Basic copper sulfate. Marcel Serciron. U. S. 2,175,132, Oct. 3. See Ger. 667,792 (*C. A.* **33**, 2662[1]).

Sodium tripolyphosphate. Ferdinand Bornemann and Hans Huber. U. S. 2,174,614, Oct. 3. A process for the prepn. of Na tripolyphosphate corresponding to the formula $Na_5P_3O_{10}$ from a Na phosphate melt having a stoichiometric $Na_2O:P_2O_5$ ratio of 1.667 comprises cooling the melt to bring it to the solidification point, and then further cooling it at an extremely slow rate below the softening temp. but above 300°, until substantially complete conversion to tripolyphosphate form is achieved.

Coherent zirconium silicates. Charles J. Kinzie (to Titanium Alloy Mfg. Co.). U. S. reissue 21,224, Oct. 3. A reissue of original patent No. 2,101,947 (*C. A.* **32**, 1067[3]).

Removing hydrogen sulfide from air. John C. Goshorn and Paul O. Rockwell. U. S. 2,175,190, Oct. 10. An adsorbent is used comprising activated charcoal impregnated with an inorg. compd. of an O acid of As such as Na arsenate.

Rectifying apparatus with bubble cap trays suitable for separating oxygen, nitrogen, argon and neon. Peter Peff. U. S. 2,175,360, Oct. 10. Various structural details.

Purifying native rock salt and other soluble materials. Thomas P. Campbell and Wm. B. Jacobsen. U. S. 2,175,178, Oct. 10. For purifying native rock salt, native borax or by-product chloride of lime, contg. a minor proportion of insol. earthy constituents as impurities, the finely divided material is introduced into an aq. soln., satd. with the compn., to form a pulp, and insol. impurities are collected in a froth-flotation treatment without material change in temp. by the action of a fatty acid compn. such as Na oleate and oleic acid, in a proportion of about 8 oz. per ton or less, while flotation of the solid but sol. constituents of the compn. is retarded, as by the use of lime or Na silicate. 5

Treating rock or evaporated salt. Marnell Segura (to Jefferson Island Salt Mining Co.). U. S. 2,174,450, Sept. 26. For maintaining it in soft, moist condition, rock or evapd. salt is mixed with an aq. soln. contg. $CaCl_2$ and water, each in an amount 0.1–5% the wt. of the salt.

Obtaining soluble products from alunite. Frank K. Cameron, Ernest O. Huffman and Joseph A. Taylor. U. S. 2,174,684, Oct. 3. Alunite is heated with an alkali metal sulfide (or with components forming such a sulfide, such as coal and K_2SO_4) supplying alkali metal more than sufficient to combine with the alumina of the alunite, to effect reaction with formation of sol. alkali metal aluminate; the resulting product is leached and the leach liquor is treated with a reagent such as a gas contg. CO_2 for pptg. alumina from the alkali metal aluminate formed and forming sol. salts of the alkali metal. 8

Activating clay. James W. Weir (one-third to Henry S. Montgomery). U. S. 2,174,610, Oct. 3. An activated clay suitable for use in treating oils, sugar solns., etc., is prepd. by bringing comminuted clay, suspended in water, into contact with SO_2 and Cl, and sepg. the activated clay from sol. products of reaction.

19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON AND C. H. KERR

The present position of the glass industry in Poland. H. Freytag. *Glastech. Ber.* **17**, 290–2(1939). J. F. H.

Artistic colors for glass. V. Ya. Lokshin and M. S. Fedorova. *Steklo'naya Prom.* **1938**, No. 7, 31–2; *Khim. Referat. Zhur.* **2**, No. 1, 85(1939); cf. *C. A.* **33**, 1894[9].—The best red Cd-Se pigments contain 10–20% of Se. Pigments contg. less than 10% of Se have an orange tint, while the shade of a pigment contg. more than 20% of Se

approaches brown. A mixt. contg. 78.6% of $CdCO_3$, 13.4% of S, and 8.0% of Se was investigated in detail. It was roasted at 540–50° for 10 min. X-ray investigation showed that the product was a solid soln. of α-CdS.-CdSe. The rich Pb fluxes were found unsuitable for the Se pigment; they were replaced by low-melting Pb-free fluxes. Best results were obtained from a color which was prepd. by the addn. of 10% of the analyzed pigment to the flux. W. R. Henn

The coloring substance in the so-called carbon yellow glasses. II. The coloring by polysulfides of glasses free from heavy metals. C. Neumann and A. Dietzel. *Glastech. Ber.* **17**, 286–90(1939); cf. *C. A.* **33**, 2296[8].—In Part I of this work it was shown that the so-called carbon yellow glasses owe their color not to carbon but to sulfides formed as a result of reducing conditions. By working with a base glass of the compn. 74% SiO_2 (synthetic with 0.0002% Fe_2O_3), 20% Na_2O, 6% CaO with $^1/_4$–$^1/_2$ of the Na_2O added as Na_2SO_4, and adding 2–3 equivs. of carbon, yellow to orange-red glasses result. Reducing conditions are used in melting. The colors are due to polysulfides, not to base metals such as iron. The presence of iron results in dull brownish colors. The yellow colors are due to lower polysulfides, while the orange-red and red colors are due to higher polysulfides. Aq. polysulfide solns. were studied for comparison with the glasses. There is close similarity in behavior of the absorption spectra. In dild. aq. solns. of Na_2S lower polysulfides are formed first, while in concd. Na_2S higer polysulfides are formed directly even with relatively small amts. of added S apparently involving only the ionized Na_2S. The present glass (high concn. of Na_2O) corresponds in behavior to a concd. soln. of Na_2S in which lower polysulfides are not stable. The color depth attainable in lower alkali glasses is less owing to greater volatility as well as to the tendency to form lower polysulfides. J. F. Hyde

Gases in glass. S. E. Nekrasov. *Stekol'naya Prom.* 1938, No. 7, 21–6; *Khim. Referat. Zhur.* 2, No. 1, 84 (1939). The changes of the amts. and the compn. of gases during melting were investigated. In a series of samples taken 11, 13 and 23 hrs. after the mixing, and in the second series after 3, 5, and 7 hrs., the total gas content was not materially changed. The compn. of the gas mixt undergoes considerable changes during the process of digesting. CO was found in the gases even when no carbonates were added to the mixt. It is concluded that the gases appear in glass as a result of the interaction of glass with the furnace atm. The gas content in glass produced in a high-frequency lab. oven was $^1/_{10}$ to $^1/_{12}$ of that in glass produced on an industrial scale. The production of gas in glass is very complex, is not the same for all grades of glass, and is caused by phys. soln. of the gas, satn. and supersatn., and by thermal decompns. connected with very complex mol. rearrangements of the different glass forming substances. W. R. Henn

A combination furnace for glass manufacture. M. G. Stepanenko, L. K. Kovalev and B. M. Polik. *Keram. i Steklo* 1938, No. 3, 31-9; *Khim. Referat. Zhur.* 2, No. 1, 122(1939).—Expts. on a semi-plant scale are described. The combination system combines the work of the shaft furnace and the bath furnace. In the shaft furnace fusion and glass formation take place; in the bath furnace degasification and homogenization occur. The usual reservoir of the glass-producing furnace is connected by means of a sloping duct to a shaft. Production is increased by this combination arrangement. W. R. Henn

The use of the dynamic viscometer in the glass tank furnace. M. S. Kazanskiĭ. *Stekol'naya Prom.* 1938, No. 10, 27–9; *Khim. Referat. Zhur.* 2, No. 3, 99(1939).—The dynamic viscometer of K. G. Kumanin was tested in the tank furnace of the Gor'kiĭ glass plant. A ball of heat-resisting steel, suspended on a steel wire, was immersed in the glass mass. The whole system was rotated by means of an elec. motor. The app. was found to react well to the changes of the η of the glass mass. The app. is graduated and gives the η in poises. W. R. Henn

Brick with a light filler. P. Solov'ev. *Keramika* 1939, No. 2, 16–17.—Clay brick can be made with an addn. of a considerable amt. of crushed pumice. E. E. S.

Determination of the moisture content of ceramic masses. S. Makarin. *Stroitel. Materialy* 1938, No. 3, 21–3; *Khim. Referat. Zhur.* 2, No. 2, 69(1939); cf. *C. A.* **33**, 5141[6].—A dielec. method for the detn. of the moisture content, and an app. for its measurement are described. The accuracy is ±1%. This app. can be utilized for the detn. of the moisture in ceramic masses. W. R. Henn

Separators (used in the ceramic industry). N. P. Vaganov. *Ogneupory* 1938, No. 1, 955–61; *Khim. Referat. Zhur.* 2, No. 1, 123–4(1939). W. R. Henn

Introduction of semiacid refractories in reheating furnaces of the Stalin New Kramatorsk Machine Works. K. I. Popov. *Ogneupory* 7, 141-3(1939).—Semiacid quartz-clay brick (sand:clay = 1:1) showed satisfactory service in a reheating furnace during 4 months in one case and over 6 months (still working) in another case and is preferred to grog brick. E. E. Stefanowsky

Acid- and alkali-resistance of some vitreous enamel ware. Amando Clemente and Loreto Alzate. *Univ. Philippines Nat. and Applied Sci. Bull.* **7**, 51–7(1939).—The resistances of com. samples of Swedish, American and Japanese enamel ware to dil. solns. of citric acid, AcOH and NaOH were detd. George Ayers

Installation of a large gas-fired continuous vitreous enameling furnace (Michael) **21**. Elec. device for burning in furnace linings of glass-melting furnaces (U. S. pat. 2,174,927) **4**.

Glass. Frederick L. Koethen and Ignatius J. Wernert (to E. I. du Pont de Nemours & Co.). U. S. 2,174,517, Oct. 3. In order to make a carbon amber glass, there is introduced into a glass melt about 1–5% of NaCN or other metal cyanide, cyanate or cyanamide.

Tank for melting materials such as glass. Henry H. Blau and Kenneth K. Knaell (to Carborundum Co.). U. S. 2,174,458, Sept. 26. In melting-tank construction, there are used a plurality of cast refractory blocks forming a wall and having seams between the blocks extending away from the material contacting surfaces of the blocks, the faces of the blocks at the seams being formed with complemental grooves, the grooves on opposed faces of each block being opposed but with the grooves on adjacent faces of the blocks being offset from each other, conduits positioned in the complementary grooves, and header pipes connected to the ends of the conduits and adapted to pass cooling fluid through the conduits, the conduits serving to hold the blocks in position and to cool the seam around each block whereby molten material attempting to escape through the seam is solidified.

Apparatus for feeding mold charges of molten glass. Karl E. Peiler (to Hartford-Empire Co.). U. S. 2,175,-407, Oct. 10. Various structural and operative details.

Apparatus for feeding and severing mold charges of molten glass. Frank L. O. Wadsworth (to Ball Bros. Co.). U. S. 2,174,905, Oct. 3. Various structural, mech. and operative details.

Ruby glass. Frank J. Dobrovolny, John M. Youel and Harold E. Klein (to E. I. du Pont de Nemours & Co.). U. S. 2,174,554, Oct. 3. A glass melt is used which contains a Cu compd. such as Cu cyanide or Cu_2O and a metal cyanide, cyanate or cyanamide such as NaCN.

Apparatus for forming hollow glass articles such as lamp bulbs. Leonard D. Soubier (to Owens-Ill. Glass Co.). U. S. 2,174,930, Oct. 3. Various structural, mech. and operative details.

Treating the interior of glass containers such as jars or bottles to effect neutralization of alkali. Oscar G. Burch (to Owens-Ill. Glass Co.). U. S. 2,175,076, Oct. 3. App. is described, and a method which involves annealing the containers, depositing in each container a quantity of a solid such as S in pellet form, which when fired creates an acidic gas, and subjecting the containers with the solid in them to an atm. of heat to fire the solid and create the acidic gas in the container.

Ornamental glass. Al Selsky. U. S. 2,174,899, Oct. 3. A method of prepg. an ornamental glass involves molding a glass plate with one surface having a desired design in bas-relief, silvering this surface, brushing the high spots of the bas-relief design to remove the Ag and produce a design in transparent glass, then applying Cu plate to the silvered surface, applying shellac to cover this side of the glass, and applying a rubber paint entirely covering the back.

Glass wool. Games Slayter (to Owens-Corning Fiberglas Corp.). U. S. 2,175,225, Oct. 10. App. is described, and a method of producing filamentous glass consisting of causing a stream of glass to flow continuously from a molten pool, reducing the temp. of the molten stream of glass to a point where it assumes a semisolid state, and subjecting a portion of the semisolid mass to a high-temp. blast within a confined area by which the reheated portion is progressively remelted and blown from the main body of the mass to form elongated fibers. Cf. *C. A.* **33**, 8287.

Apparatus for supporting glass sheets during case hardening. Lloyd V. Black (to Pittsburgh Plate Glass Co.). U. S. 2,174,254, Sept. 26. Various structural, mech., elec. and operative details.

Extrusion press for producing foils or plates of materials such as polymerization products for use with glass. Adolf Kampfer. U. S. 2,175,961, Oct. 10. Various structural, mech. and operative details.

Sealing glass to metals. Thomas A. Elder (to General Elec. Co.). U. S. 2,174,381, Sept. 26. A metal container such as that of an elec. discharge device with a metallic tubular projection passing through its wall has an elec. conductor such as a metal rod passing through the tubular projection and sepd. from its walls by glass fused vacuum-tight to the projection and conductor, the surface of the projection to which the fusion is made being of an alloy of Ni 28, Co 18 and Fe 54%. U. S. 2,174,382 (Thomas A. Elder and Albert C. Gable, joint inventors (to same assignee)) also relates to similar devices.

Glass seals for metal pieces such as those of metal vacuum tubes. Donald V. Edwards (to Electrons, Inc. of Del.). U. S. 2,175,019, Oct. 3. For sealing, a glass is used of the approx. compn.: Na_2O 20, SiO_2 60 and FeO 20%, which is highly elastic and tough so that after being melted to form the seal it does not rupture upon cooling.

Composite bulbs or lamps of metal, glass and ceramic material. Hans Pulfrich (to General Elec. Co.). U. S. 2,175,916, Oct. 10. A metal part has bonded to it a glass contg. approx.: SiO_2 56, Na_2O and K_2O 12, PbO 32 and Al_2O_3 1 part, and to the glass there is fusion welded a joint of ceramic material fired at an elevated temp. which may contain MgO 65–80, Be oxide 35–20 and TiO_2 0.5–2 parts. Such a product is readily made gas tight.

Joints for metal and ceramic materials such as those of spark plugs. Charles M. Carington (to K. L. G. Sparking Plugs Ltd.). U. S. 2,174,913, Oct. 3. A metal part such as a sleeve or collar and a ceramic part such as an insulator are joined by 2 or more intervening layers of foil of soft metal such as Al.

Use of styrene in sealing ceramic and metallic parts such as those of electric fittings. Thomas R. Scott and Leonard A. C. Pooley (to International Standard Elec. Corp.). U. S. 2,175,672, Oct. 10. A method of sealing the metallic part of an electrical fitting to a ceramic part thereof involves providing a filling of a cementing material mainly of styrene between the metal and ceramic parts of the fitting, providing a gasket contg. a small amt. only of sytrene at an exposed surface of the cementing material and then hardening the cementing material and the gasket by polymerization of the styrene *in situ* to bond to the walls of the electrical fitting parts and to the gasket.

Tiles suitable for use on wall surfaces. David Broadwin. U. S. 2,175,660, Oct. 10. Tiles are formed with a corrugated rear surface which is coated with paint and with an overlying layer of sand the granules of which project beyond the outer surface of the coating of paint.

Ceramic spacer material for electron-discharge devices. Lawrence R. Shardlow (to Radio Corp. of America). U. S. 2,175,707, Oct. 10. An electrode holding and insulating material of porous ceramic character is used comprising MgO 6.5–11.5, SiO_2 26–44.5 and Al_2O_3 46–66%.

Bonding abrasive grains with synthetic resins. Emil E. Novotny (to Durite Plastics, Inc.). U. S. 2,174,755, Oct. 3. For the production of articles such as slabs, abrasive grains are mixed with a resinous coating liquid such as "Durite No. S-1719" and a pulverized potentially reactive resin such as "A" stage "Durite No. KV-1000-B" in proportions to produce an initial wet mixt. which upon standing "converts itself" to a dry moldable mixt. which is formed into the desired article and hardened, as by heating.

Waterproof abrasive articles such as disks. Herbert R. Stratford (to The Stratmore Co.). U. S. 2,174,902, Oct. 3. A relatively rigid disk formed of a phenol condensation product and uniformly distributed abrasive particles has its outer portion thicker than the central portion, and has a working surface of substantial area in a plane normal to the axis of the disk.

Abrasive disks. John O. Amstuz (to Behr-Manning Corp.). U. S. 2,175,073, Oct. 3. A single layer of abrasive grains is attached to one side of a perforated thin sheet of metal such as steel by a flexible nonporous bonding material such as glue or a synthetic resin extending through the perforations of the metal to anchor the grains to the latter

20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

Survey in seventeen cement plants of atmospheric dusts and their effects upon the lungs of twenty-two hundred employees. Leroy U. Gardner, Thomas M. Durkan, Daniel M. Brumfiel and Homer L. Sampson. *J. Ind. Hyg. Toxicol.* **21**, 279–318(1939).—Very few workmen in this industry are exposed to high-silica dusts. Although dust counts are frequently high the incidence of lung infections is less than that in the general population. 2378 workmen were exaind. and only 8 showed evidence of nodular fibrosis and in 6 of these previous employment was presumably responsible. A. L. Elder

Cement from Kerch Iron and Steel Works blast-furnace slags. A. G. Tevfikov. *Tsement* **6**, No. 4/5, 57–9(1939). E. E. Stefanowsky

Fungicidal oils [for impregnating wood] (U. S. pat. 2,174,258) **15.**

Fixing pervious or loose subsoil layers. Jan van Hulst (to Patent and Licensing Corp.). U. S. 2,175,804, Oct. 10. A process for making impervious, tightening or fixing pervious or loose subsoil layers such as sand soils or other porous masses comprises first introducing an aq. dispersion of bitumen into the mass to form a partially impermeable partition, and subsequently introducing an impermeabilizing agent to form an impervious screen against the partially impermeabilized partition.

Mixture for coloring gravel, sand or shale particles, etc. Ernest G. Hewish (50% to Carl Buchholz). U. S. 2,174,632, Oct. 3. A mixt. is used contg. a color base such as chrome green or toluidine red 8–20, $CaSO_4$ 25–50, boiled linseed oil 5–10, resin varnish 15–30, pilchard oil 10–20 and Co drier 1–4%.

Shingles covered with a mat of glass fibers. Games Slayter (to Owens-Corning Fiberglas Corp.). U. S. 2,175,226, Oct. 10. Shingles such as those of tarred paper have their upper surface covered with a mat of glass fibers with open air-filled interstices.

Artificial building blocks etc. Karl E. Haustein. **U. S. 2,175,568, Oct. 10. Fibrous material such as rye**

straw is digested by an alk. chem. treatment, as with a 3° Bé. "lime-sodium lye" and the digested material is rinsed, then treated with a substance such as clay, adapted to lower its water-absorbing quality, then mixed with a pulp of cement and water, and molded and dried under pressure.

Floor- and wall-covering material. Hugo Strauch (to I. G. Farbenind. A.-G.). U. S. 2,175,096, Oct. 3. An inorg. filler such as stone flour is used with about 15–30% its quantity of an org. filler such as wood meal incorporated with an aq. emulsion of stand oil, a drying oil, an alkyd resin of soft consistency comprising a radical of a fatty acid derived from a drying oil or an oil lacquer, and an emulsifying agent (the filler and emulsion being proportioned to form a product which is moist like wet earth but not sticky). Various examples are given.

Wood preservative and stain. Percy L. Gardner. U. S. 2,175,115, Oct. 3. A highly penetrative compn. suitable for treating various woods contains crude pine gum 5, dehydrated pine oil free tar 7, and low-temp. distd. pine oil 9 parts as a penetrating solvent for the tar and gum.

21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER AND A. GEORGE STERN

Evaluation of certain normal alkylated benzenes as Diesel fuels. Gann Shen, C. E. Wood and F. H. Garner. *J. Inst. Petroleum* **25**, 695–703(1939).—The prepn. and phys. properties of Am benzene, hexylbenzene, heptylbenzene and nonylbenzene are given. The cetane no. of Am benzene is 8, hexylbenzene 26, heptylbenzene 35 and nonylbenzene 50. The lines representing the cetane no. of blends of a high reference fuel and of the pure hydrocarbons are curved in all cases; the curvature becomes greater the lower the mol. wt. of the hydrocarbon. Am benzene shows the poor ignition quality found in aromatic hydrocarbons. The aniline pt. has no significance in the evaluation of these hydrocarbons. Joseph H. Wells

Diesel-fuel characteristics influencing engine output. V. J. Blackwood and G. H. Cloud. *J. Inst. Petroleum* **25**, 684–94(1939).—Diesel fuels were tested in a 6-cylinder $5^1/_4 \times 4^1/_2$, antichamber engine capable of running up to 2000 r. p. m. for those fuel factors influencing power and fuel economy. For const. cetane no., the volumetric fuel economy improves with increasing mid-b. p. For either const. gravity or cetane no., an increase in mid-b. p. of a fuel is accompanied by an increase in heating value per gallon. Under low-speed conditions, the best consumption is obtained on the fuel of highest heating value whereas at high speeds, the fuel of superior ignition quality gives greater fuel economies. The low-viscosity fuels show somewhat higher consumption than might be expected from heating values. Joseph H. Wells

Experiments with doped fuels for high-speed Diesel engines. J. J. Broeze and J. O. Hinze. *J. Inst. Petroleum* **25**, 657–77(1939).—The effect of adding acetone peroxide as a dope to straight-run gas oils expressed either as an increase in the cetene no., or as a decrease of the ignition delay, decreases as the amt. of dope increases. The effect of the dope will be greater the greater the "chem." part of the ignition delay and does nothing to shorten the "phys. delay." The effect of a dope expressed in delay time is lower in a high-speed engine than in a low-speed engine. The addn. of dope to a fuel has little influence on the combustion process as a whole apart from its effect on the ignition quality. The amt. of incrustations and piston ring wear is slightly higher with a doped fuel than with an undoped fuel. Storage of pure $EtNO_3$ for several years has no influence on its effectiveness as a dope. Fuel doped with acetone peroxide is stable during storage. Acetone peroxide as a dope has no effect on the flash point. $EtNO_3$ decreases the flash point of the fuel. Joseph H. Wells

The application of graphical and statistical methods of hydrocarbon analysis to Diesel fuels. J. C. Vlugter, H. J. Waterman and H. A. van Westen. *J. Inst. Petroleum* **25**, 678–83(1939).—Cetene values of Diesel fuels as calcd. by Kreulen's formula (*C. A.* **31**, 5141[4]) do not agree with the detd. values. The differences are smaller if the same formula is used for calcg. the cetane values. J. H. W.

Motor fuel from butane cracking and catalytic polymerization. G. Egloff and J. C. Morrell. *Atti X° congr. intern. chim.* **3**, 734–41(1939)(in English).—The conversion of natural gas into motor fuel by a combination of gas cracking and catalytic polymerization as carried out on com. scale at the Shamrock Oil and Gas Corporation, Amarillo, Texas is described. Joseph H. Wells

Effect of carburetor adjustment, spark advance, richness and admission temperature of fuel on fuel consumption. G. Simon. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 582–94(1937)(in French).—Tests carried out to det. the savings possible by making various adjustments of carburetor, spark advance, fuel inlet temps., etc., in a single engine and at const. speed confirm the previously obtained results, although these tests are considered to be incomplete. E. J. Mahler

Influence of fuel richness and compression ratio on cylinder-head temperatures. Puisais. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 578–81(1937)(in French). The effect of motor-fuel mixts. of varying richness and at different compression ratios on cylinder-head temps. was studied in the CFR-ASTM test engine. The temp. was recorded at the spark-plug joint, in the plug itself and on the bouncing pin either at the joint or at the cylinder wall. An unequal distribution of fuel in the carbureted mixt. at the different points of the cylinder head was observed. Turbulence had a decided effect on local rises of temp. as a function of the compression. The relation between temp. and detonation varied with the fuel and with the test conditions. Addn. of tetraethyl lead had no appreciable effect on the working temp. at the same compression ratio. E. J. Mahler

Principal combustion features in explosion motors and devices for detecting and recording them. Max Serruys. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 560–5(1937)(in French).—S. defines and discusses the following features of combustion: detonation proper, pseudo-detonation, self-ignition, pre-ignition, knock and post-combustion. The merits and disadvantages of devices for recording and detecting these phenomena are pointed out. The "Detonindex," an invention of S. and used by him for 5 years, is an app. consisting of a membrane rigidly spread with a calibrated spring held in contact with the membrane at one point where a bead is held attached. Slight vibrations are not recorded. Vibrations equiv. to detonations are recorded by the breaking of an elec. contact causing a neon tube to light as a result of each detonation. Connection with a galvanometer permits the intensity of the detonation to be recorded. In this way weak but frequent detonations, and the more violent but less frequent detonations can be recorded. E. J. Mahler

Incomplete combustion products in explosion motors. A. Maillard. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 557–9(1937)(in French).—Exhaust gases were collected in a special app. and analyzed. From the oily and water layers M. isolated products of a widely differing nature, e. g., acidic compds., neutral cracked compds., and other substances probably of an aldehydic nature which resinify at low temps. forming substances analogous to those causing ring-sticking. E. J. Mahler

Gum formation on pistons in internal-combustion engines. C. A. Bouman. *IIme Congr. mondiale pétrole* **3**, Sect. 4, 524–8(1937)(in French).—For gasoline and direct-injection Diesel engines the piston temp. is the most important factor. The higher the temp. the more pronounced is the amt. of gum. Gumming at low temps. is almost negligible. Detonation in gasoline engines and sooty combustion in Diesel engines increase piston temps.

and hence the amt. of gum formed. Although the basic properties of the lubricating oils in the motor may be responsible for gum formation to a certain extent, the extreme operating conditions of the engine have a greater bearing on gum, and C deposits. Exptl. results are reported. E. J. Mahler

The determination of sulfur in solid fuel and in pyrite by combustion in oxygen. A. Seuthe. *Glückauf* **75**, 409–11 (1939).—S in solid fuels can be readily detd. by means of a small combustion furnace and a special absorbing bulb. A 1-g. sample is placed in a porcelain boat and introduced into the furnace at 1200–1250°. A rapid stream of O_2 is passed over the sample for 8 min. and the SO_2 or SO_3 produced is absorbed in a 1% soln. of H_2O_2. The H_2O_2 is then titrated with 0.05 *N* NaOH with methyl red as an indicator. One cc. of 0.05 *N* NaOH is equiv. to 0.08% S. The same method is used to det. S in pyrite except that a higher furnace temp. about 1450° is required and a larger vol. of H_2O_2 for absorption with stronger NaOH used in titrating. The higher temp. is necessary completely to burn the ash. L. P. Rockenbach

Briquetting, with special reference to the agglomeration of substances by pressure without the use of a binder. Hans Maul. *Chem. Fabrik* **1939**, 483–6.—With reference to earlier work (*C. A.* **14**, 886; **16**, 4122) the briquetting in tablet form of 150 constitutionally well-defined org. and inorg. compds. was investigated in regard to stability, compression strength, flexibility, Brinell hardness, flow under pressure, the effect of compression temp. and tablet form, aging and fatigue. The substances were prepd. for briquetting as in *C. A.* **31**, 7200⁴. Results are tabulated. J. H. Moore

Coal preparation in 1937. A. Götte. *Glückauf* **74**, 1065–79, 1093–1101, 1117–24(1938); cf. *C. A.* **32**, 8108⁴.—Progress in various countries is reviewed. Numerous illustrations are given of screening and washing plants, slurry-treatment systems, etc. B. C. P. A.

Practical determination of probable distribution of density characterizing coal-washing. André Terra. *Rev. ind. minérale* No. **446**, 409–13(1939); cf. *C. A.* **33**, 1470⁶.—The definition of the probable distribution of density resulting from, and measuring the efficiency of, coal washing, is amplified; and a simple method of detg. it (with examples) is described. C. A. S.

Coal gasification in suspension. Wilhelm Gumz. *Feuerungstech.* **27**, 257–9(1939); cf. *C. A.* **33**, 8956⁴. George Ayers

Use of city and natural gas for metal cutting. Carl Wierum. *Gas* **15**, No. 12, 29–30(1939).—When city gas is used at a pressure of about 12 lb. per sq. in., O requirements and speed of cutting metal are approx. the same as for C_2H_2. Some experimentation may be required to secure the best flame adjustment as the appearance of the flame is different from that of the C_2H_2–O flame. Precautions must be taken to avoid any back flow of O and to minimize any flashback. R. W. Ryan

The installation of a large gas-fired continuous vitreous enameling furnace. A. F. Michael. *Gas* **15**, No. 12, 34–5 (1939).—A continuous vitreous enameling furnace 82 ft. long is fired with natural gas by means of premix burners. The max. capacity of this furnace is 3000 sq. ft. of coated surface per hr.; gas requirements are about 6500 cu. ft. per hr.; this varies little with throughput. The furnace is never cooled below 1300°F. which requires 2500 to 3000 cu. ft. of natural gas during nonworking hrs. Details of the furnace and the (external) conveyor system are given. R. W. Ryan

Butane-air does standby service at Colusa, California. Harry F. Smith and John K. Heller. *Gas* **15**, No. 12, 42–4(1939).—App. is provided for making a 1300-B. t. u. butane-air gas (58% air) for emergency use in place of the normal 1015 B. t. u. natural gas. This gas will be distributed at 21 in. (water column) pressure as against 10 in. for the natural gas. Equipment is illustrated and described. R. W. Ryan

Gas-purification masses. W. Mantel and F. Backenköhler. *Glückauf* **74**, 661–9(1938).—A method for detg. the activity and capacity curves of bog Fe ore-Luxmasse mixts. is described. The reaction of fresh and spent masses after heating to high temp. with gases contg. H_2S is discussed. The activity appears to depend on the ability of the mass to absorb H_2O, and the capacity of the H_2O content and pH value. B. C. P. A.

Corrosion prevention by high purification of fuel (illuminating) gas. Horst Brückner. *Chem. Fabrik* **1939**, 489–93.—Moisture is the most fundamental cause of corrosion in gas as commonly delivered to pipe lines, both on account of its action on Fe and of its tendency to dissolve traces of other impurities. The advantages of thorough drying and the removal of oxides of N, org. S compds. and other org. compds. are discussed and methods for their removal outlined. 26 references. J. H. Moore

Hydrogen sulfide removed by tripotassium phosphate. H. N. LaCroix and L. J. Coulthurst. *Natl. Petroleum News* **31**, R-326, 27, 29, 30, 32; *Refiner Natural Gasoline Mfr.* **18**, 334–8(1939); cf. *C. A.* **33**, 9604⁸.—Cracked gas is treated with K_3PO_4 to remove H_2S. When used to purify gas for polymerization processes the operating temp. is up to 200°F. with a 31.8% soln. The soln. at equil. will contain 3000 times as much H_2S as a liquid C_3–C_4 mixt. The soln. is regenerated by heating with steam at 225–240°F. H_2S is removed from the H_2O in a stripper operating at a top temp. of 90°F. The regenerated soln. is recirculated. Countercurrent scrubbing is used. The H_2S content is reduced from as much as 3000 grains/100 cu. ft. to as little as 15 grains/100 cu. ft. W. L. B.

Increasing the content of phenols in tars. U. B. Lobkov. *Coke and Chem.* (U. S. S. R.) **1938**, No. 8–9, 42; *Khim. Referat. Zhur.* **2**, No. 1, 87(1939).—In order to obtain the light-medium fraction with the standard amts. of phenols it was necessary to lower the yield of this fraction. To obtain products of standard quality it is proposed to increase the content of phenols in the tar by improving the regime of the coke furnaces. W. R. H.

High-pressure hydrogenation of low-temperature tar. XIV. Re-processing of fractions of hydrogenated oil. Singo Andō. *J. Soc. Chem. Ind., Japan* **42**, Suppl. binding 268–71(1939); cf. *C. A.* **33**, 9596⁹.—Two products, one from mild and the other from severe hydrogenating conditions, were obtained from Hōkoku coal hydrogenation at approx. 480° and 200 atm. pressure with a type of Mo catalyst. The first product was sepd. by distn. into gasoline (b. up to 200°), middle oil (b. 200–300°) and heavy oil (b. over 300°), while the second product was sepd. by Hempel distn. into gasoline (b. up to 190°) and middle oil (b. over 190°). The 5 fractions (250–350-g. samples) were resp. subjected to hydrogenation at 463–470° in the presence of NH_4 thiomolybdate-asbestos or MoO_3 (25–45 g. catalyst) under an initial H_2 pressure of 90–100 atm. (0°) for 60–120 min. The middle-oil fractions gave high yields of gasoline, but the heavy-oil fraction was more difficult to break down. Both gasoline and middle-oil fractions increased in aromatic hydrocarbon content, while the former also increased in naphthene content. G. A.

The behavior of the so-called organic coke sulfur in coke at temperatures over 1000°. Iv. Trifonov. *Atti X° congr. intern. chim.* **3**, 659–65(1939)(in German).—A sample of metallurgical coke and coal-tar pitch coke prepd. at 1000° was extd. with acid to remove inorg. S compds. By distn. of the cokes in a N or H atm. at temps. of 1100° to 1500° there is only slight volatilization of S. At temps. above 1500°, the S volatilization curve is linear and reaches 100% at 2000°. H slightly increases the rate of volatilization of S. Joseph H. Wells

Coal veins in Malaya (Fermor) **8**. Cleavage of heterocyclic compds. of coal tar (Kruber) **10**. 1,5-Dimethylnaphthalene in coal tar (Kruber, Marx) **10**. Trimethylnaphthalenes in coal tar (Kruber) **10**. Treating [gas] wells penetrating calcareous earth formations (U. S. pat. 2,175,079) **22**. Treating gas wells with HCl to increase production (U. S. pat. 2,175,095) **22**. Use of acid in gas wells to increase production (U. S. pat. 2,175,081) **22**. Recovering liquefiable hydrocarbons from strata penetrated by [gas] wells (U. S. pat. 2,174,336) **22**.

Diesel fuel. Darwin E. Badertscher and Geo. S. Crandall (to Socony-Vacuum Oil Co.). U. S. 2,174,680, Oct. 3. A fuel oil for use in Diesel engines is prepd. by a process which involves dissolving Ac_2O in a hydrocarbon oil suitable for use as a Diesel fuel and oxidizing the Ac_2O *in situ* (suitably by use of BaO_2) to diacetyl peroxide, which serves as an ignition accelerator.

"Hydrofining" carbonaceous vapors such as those of motor-fuel distillates. Marion H. Gwynn. U. S. 2,174,510, Oct. 3. An arrangement of app. is described, and a method of continuously "hydrofining" vapors which comprises continuously bringing the vapor and an excess of H in a series of time stages into contact with a solid S-sensitive catalytic surface contg. a catalytic metal, such as Ni or Cu, the pptd. sulfide of which is black, at a plurality of temps. above about 75° but below the temp. at which substantial pyrolysis occurs with the vapor, and adjusting the temp. and H excess of each of the time stages so that relatively equal amts. of hydrofining occur in each of the stages, the plurality of temps. consisting substantially of an ascending time gradient of temp., the rise of temp. occurring as the catalytic surface becomes progressively spent, the difference between the extremes of the gradient being between about 20° and 200°, while the pressure of each stage is maintained between about 1 and 100 atm.

Apparatus for making briquets such as those of coal. John F. Crawford (to J. I. Case Co.). U. S. 2,175,342, Oct. 10. Various structural, mech. and operative details.

Continuous gasification of solid fuels such as coal or coke. Willy Linder (to Koppers Co.). U. S. 2,175,610, Oct. 10. App. is described, and a method of continuous gasification of solid fuels by reaction thereof with a mixt. of preheated air and steam comprising, maintaining a bed of continuously descending fuel; charging the fuel at the top of the bed and withdrawing the made gas continuously from the upper part of the bed; subjecting the fuel in the lower part of the bed to continuous mech. rotative agitation and ash-crushing action and continuously discharging the ash thereof in solid form from the bottom of the bed; introducing a mixt of very highly preheated air and steam into the fuel bed through the circumference thereof at a zone somewhat above the region of mech. agitation and causing the same to flow upwardly through the bed for reaction therewith and withdrawal at the upper part thereof; and concurrently with the introduction of the very highly preheated air and steam separately introducing steam and relatively cooler air into the lower portion of the bed through the mech. agitation medium to cool the same and diffusing the steam and relatively cooler air from the mech. medium into the portion of the fuel bed between the mech. medium and the region of entrance of the very highly preheated air and steam for combustion of combustible residues of the ash and causing the gas thereof to flow upwardly through the fuel bed for off-flow therefrom together with the very highly preheated air and steam introduced to the fuel bed circumferentially thereof somewhat above the mech. medium.

Water gas. Max Radtke (to Koppers Co.). U. S. 2,175,613, Oct. 10. An arrangement of app. is described, and a process for the continuous production, from distillable bituminous fuel, of water gas practically free from hydrocarbons for subsequent synthesis to hydrocarbons for motor fuel, which involves circulating a gaseous heat carrier comprising a highly heated water gas and steam mixt. in cycle through a gasification step, in which the distillable fuel is both distd. by the heat of the gaseous heat carrier to liberate hydrocarbons from the fuel and is also caused to react with the steam in the heat carrier to form water gas, and thence from the gasification step to and through a reheating step for the carrier, in which the liberated hydrocarbons in the carrier from the gasification step are caused to react to water gas and the carrier also reheated for return to the gasification step; the process further involves causing water gas newly generated in each cycle of flow of the carrier to flow through the gasification step also along to the reheating step together with the heat carrier and with the hydrocarbons distd. off in the gasification step during their return to the reheating step for conversion of the hydrocarbons to water gas and reheating of the carrier, and withdrawing the final end product water gas from the process from the reheated carrier after it has been reheated in the reheating step and before the reheated heat carrier reënters the gasification step. Cf. *C. A.* **33**, 4001[6].

Apparatus for introducing odorous vapors into gas lines. Robert M. Hutchison and Frank Y. Hutchison. U. S. 2,175,526, Oct. 10. Various structural and operative details of an app. suitable for introducing vapors such as those of "Calodorant" into natural gas lines, etc.

Determining combustible matter in waste gases from gas-fired furnaces. Dominick Labino (to Owens-Ill. Glass Co.). U. S. 2,174,923, Oct. 3. The combustibles in the gas are ignited and simultaneously the elec. cond. change in the gas is registered. Various details of app. are described.

Coke ovens with internally heated movable heating walls. Franz Puening. U. S. 2,174,832-3, Oct. 3. Various structural and operative details.

Coke-oven retort. Gustaf E. Salkvist (to Koppers Co.). U. S. 2,175,217, Oct. 10. Various structural details of door fastening, etc.

22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER AND STUART S KURTZ, JR.

Preparation of bright pyrolyzed resins from pyrolyzed petroleum products. I. E. Bespolov. *Azerbaĭdzhanskoe Neftyanoe Khoz.* **1938**, No. 11, 25–30.—The best (lightest) pyro-resins are obtained by using 3% of a 98% H_2SO_4, lighter fractions yielding a better product. Thus, by applying 8–10% of H_2SO_4 there can be obtained pyro-resins which can be used in the prepn. of oilcloth after the introduction of oil driers. Co oleate was found to improve the quality of the pyro-resins to such an extent as to produce absolutely white films. Oil drier "No. 12" also gives good results, although the color of the resins is not as satisfactory. Four % of it is added at a temp. not in excess of 50°. A mixt. of pyro-resins contg. 4% of oil drier "No. 12" and not less than 20% pyro-resins may replace pure oilcloth oil drier in the prepn. of light oilcloths. The ratio of pyro-resins may be increased when plasticizers (castor oil) are introduced. The expts. are described.

A. A. Boehtlingk

Hydrogen sulfide in Ishimbaevo crude oil. V. G. Plyusnin, E. A. Nikonova and S. S. Spasskiĭ. *Neftyanoe Khoz.* **1939**, No. 2, 46–9.—Ishimbaevo and the upper horizon Krasnokama crude oils contain dissolved H_2S; other oils such as those of Chusovskie Gorodki, Samarskaya Luka, the lower Krasnokama horizon do not contain H_2S. Krasnokama oil from the lower horizon forms pyrogenetic H_2S at about 300°. Ishimbaevo oil seps. pyrogenetic H_2S on straight distn. in the amts. of 7 kg. per ton of oil at 300° in one hr. The source of pyrogenetic H_2S at 350° is elementary S and compds. having a S grouping similar to that of the disulfides. In Ishimbaevo crude oil up to 68% of the pyrogenetic H_2S is from S compds. of the asphalt-resinous part of the crude oil and only 32% from the S compds. of the kerosene-lubricating oil fractions.

Modern instrumentation for topping, cracking and polymerization plants. Donald J. Bergman. *Refiner Natural Gasoline Mfr.* **18**, 304–11(1939); cf. *C. A.* **33**, 9605[9].

W. L. Benedict

Economics of catalytic polymerization of natural butanes. F. B. Mack. *Refiner Natural Gasoline Mfr.* **18**, 330–4(1939); cf. *C. A.* **33**, 7991[9]. W. L. Benedict

Coöperative catalytic polymerization plant operates at

1100–1200 pounds. M. G. Van Voorhis. *Natl. Petroleum News* **31**, R270, 71, 73(1939). W. L. Benedict

Color density and acid vapor indicate oil performance. W. F. Weiland. *Natl. Petroleum News* **31**, R334, 36, 38 (1939).—The oxidation tendencies of lubricating oils are measured by visible changes in color density, and corrosion and sludging tendencies are measured by the temp. at which acid vapors form. These relationships are shown graphically. W. L. Benedict

The action of aqueous solutions of acids on the liquid-phase pressure distillate. V. Butyrya and V. Bulnitskaya. *Azerbaidzhanskoe Neftyanoe Khoz.* **1938**, No. 5, 47-50; *Khim. Referat. Zhur.* **2**, No. 1, 89–90(1939).—The removal of the unstable substances from cracked gasoline by means of aq. solns. (5%, 15% and 30%) of H_2SO_4, HNO_3, H_3PO_4 and HCl as well as 10% and 15% aq. solns. of AcOH and $(COOH)_2$. The individual fractions as well as gasoline as a whole were treated with the acids. The treatment with HNO_3 gave a definite picture of the nitration process. The treatment of gasoline with aq. solns. of $(COOH)_2$ and of AcOH under pressure decreased sharply the induction period of the distn. W. R. Henn

Hydrogenation of Dubroval vapor-phase cracked gasoline. V. Getling, A. Sosnina and L. Stepantsev. *Novosti Tekhniki* **1939**, No. 19, 31–3.—Data are given on the hydrogenation of gasoline obtained in the Dubroval vapor-phase cracking. The gasoline was hydrogenated in the presence of MoS_2 at 25-100 atm. and 400°. The ratios of gasoline vapors to H were 1:2, and 1:4. The most thorough hydrogenation was obtained at 100 atm. regardless of the gasoline/H ratio. A reduction in the pressure decreased the speed of hydrogenation. A drop in the temp. to 340° also reduced the speed of hydrogenation. The hydrogenated gasoline had a high stability, an octane no. of 71-72, and a good susceptibility to tetraethyl lead. B. Z. Kamich

Desulfurization of gasoline with pyrite dross. M. Blagodarov. *Novosti Tekhniki* **1939**, No. 16, 33 4. -In the desulfurization of gasoline by the Frasch method the gasoline vapors passed through a column of pyrite dross consisting chiefly of Fe and Cu oxides. The spent packing can be partially regenerated by blowing with superheated steam at 400°. For complete regeneration the packing is removed from the column and calcined to convert the S compds. into oxides. B. Z. Kamich

The chemical composition and the antiknock properties of fuels. I. A. Rogozin. *Tekhnika Vozdushnogo Flota* **1938**, No. 8, 26–33; *Khim. Referat. Zhur.* **2**, No. 2, 112-13 (1939).- A general discussion of the causes for knocking. The primary process of oxidation and its intensity are influenced by the period of the gasoline mixt. in the zone of high temp. and by the stability of the components of the fuel (hydrocarbons) in relation to the oxidation process. The antiknock properties of different hydrocarbons are compared with some of their phys. consts. and with the relative contents of different hydrocarbons in gasolines of different origin. W. R. Henn

Lowering the solidification point of transformer oils. L. A. Aleksandriiskaya. *Novosti Tekhniki* **1938**, No. 11-12, 46-7.—By adding 0.1-0.3% paraflow to Emba transformer oils it was possible to lower the solidification points to the specified values. Elec. properties were not affected by the addn. of as much as 0.5% paraflow. The solidification points of Emba oils which had been refined with selective reagents were lowered by 9-14° depending on the amt. of paraflow added. Addn. of 0.2–1.5% paraflow to mineral oils of paraffinic base reduced the solidification point by 20–25°. Baku oil having a solidification point not lower than −45° is not affected by the addn. of paraflow. B. Z. Kamich

Laboratory method for evaluating the influence of lubricating oils on carbon deposition in internal-combustion engines. H. A. Everett and G. H. Keller. *Penna. State Coll. Bull., Eng. Expt. Sta. Ser., Bull.* No. **48**, 35 pp.(1939).—A simplified and inexpensive lab. test for predicting the C-forming characteristics of lubricating oils utilizes a battery of small, single-cylinder engines. Mechanical devices for measuring C formation were not very successful. When the oil was overheated without actual contact with flame or the incandescent products of combustion, no appreciable C was deposited (though lacquer was), but when the oil was similarly treated in contact with flame or incandescent products of combustion, C was deposited. In tests with com. engines, after thorough cleaning of the engine with gasoline, the cylinder heads were weighed to 0.001 g. Each test was conducted for five 8-hr. periods and the heads were weighed at the end of each period. The pistons were weighed only at the end of the test. After each test of an oil a 40-hr. test was made with a reference oil consisting of a blend 180 Penna. neutral oil and Penna. overhead bright stock. The data were plotted against time, to give a curve of the av. cylinder-head C formation for each oil. It is doubtful if the accuracy of individual results is closer than about ±10%. Although this method does not give a final answer on any one oil it should select oils that are good or bad as to C formation. Further tests on full-scale engines could then be carried out. A bibliography (with brief abstracts) is included. Saverio Zuffanti

Effect of fatty acid derivatives on lubricants. IV. Lubricating properties of aliphatic esters. A. W. Ralston, E. J. Hoffman and E. W. Segebrecht. *Natl. Petroleum News* **31**, R320, 322(1939); cf. *C. A.* **33**, 8975⁸.—The effect of added esters and thioesters of fatty acids was detd. by measuring the increase in temp. (°F.) due to friction on a bearing surface of the untreated oil and oil contg. 0.5% of addn. agent. The original oil was 96.4°F., Et palmitate 79.0°F., Pr laurate 81.8°F., Pr myristate 83.1°F., Bu myristate 78.6°F., Bu palmitate 79.6°F., Am palmitate 74.3°F., Et oleate 88.0°F., Et esters of unsatd. fish oil acids 92.5°F., Pr esters of unsatd. fish oil acids 90.2°F., Me thiollaurate 86.5°F., Me thiolmyristate 85.8°F., Me thiolpalmitate 83.7°F., Me thiolstearate 84.3°F., Et thiollaurate 84.1°F., Et thiolmyristate 81.0°F., Et thiolpalmitate 86.5°F., Et thiolstearate 82.7°F., Pr thiollaurate 83.3°F., Pr thiolmyristate 87.9°F., Pr thiolpalmitate 85.6°F., Pr thiolstearate 81.0°F., Pr thiololeate 83.2°F., Bu thiollaurate 87.2°F., Bu thiolmyristate 82.4°F., Bu thiolpalmitate 85.0°F., and Bu thiolstearate 81.8°F. The esters of satd. acids were more effective than the corresponding unsatd. esters. The thiol esters were less effective than the corresponding O_2 esters. W. L. B.

Automobile manufacturer's selection of lubricants. K. Brozyna: *J. Inst. Petroleum* **25**, 629–48(1939).—There are discussed for *engine oils* (*a*) the fallacy of working to specifications only, (*b*) the importance of new methods of refinery and addn. agents, (*c*) oil filters, (*d*) selection of oils, (*e*) running tests, (*f*) effect of oils on the engine, and (*g*) cold-room tests; characteristics of suitable *gear-box oil lubricants;* for *rear-axle lubricants* (*a*) extreme-pressure lubricants, (*b*) attempts to correlate the results of lab. scoring tests with those under road conditions, (*c*) torsion loaded gear-testing fixture, and (*d*) selection of worm gear lubricants; selection of *semisolid lubricants* for *chassis lubrication.* Saverio Zuffanti

Service tests with lubricants for high-speed oil engines. A. T. Wilford. *J. Inst. Petroleum* **25**, 607–22(1939); cf. *C. A.* **33**, 3644.—A discussion of lubricating-oil tests conducted by the London Passenger Transport Board covering a period of intensive development in the application of oil engines to passenger vehicles. Steps leading to the drafting of a first specification for lubricating oils for this type of engine are described, and data given pointing to a close relationship between hard asphalt produced in an oil during use and that produced in an oxidation test of the Air Board Type. The discussion also includes investigations involving detn. of the optimum periodicity of oil changes, the efficiency of a flushing oil for cleaning engine-bases, and the useful life of engine-oil by-pass filters. Results of tests with solvent-refined oils are summarized. Compared with the lubricant originally standardized in 1932, oils complying with the specifications quoted in an included appendix increased engine mileage by 11%, reduced oil consumption by nearly 7%, reduced cylinder wear by 13.5%, and decreased engine failures due to seiz-

ures and bearings by 60%. The oil has been adopted despite its much higher cost. It is estd. that a net yearly saving of a few thousand pounds will result. Experience to date proves that engines are cleaner internally than before, and in spite of some "lacquering" no trouble has been encountered. Saverio Zuffanti

Manufacture of lubricating greases and high-pressure lubricants. W. Maass. *Seifensieder-Ztg.* **66**, 172–4, 196–7, 256–7, 278–9, 298–9, 318–19, 338–9, 358–9, 377–8, 397, 417–18, 437–8, 457–8, 477–8, 497–8, 517, 557–8, 577–8, 597–8, 637–8, 657–9, 690–1, 713–14, 731–2, 745–6, 775, 785, 795, 805, 815, 825(1939).—The review presents the uses, underlying theory, raw materials and methods of manuf. of lubricants, including 101 formulas. Brief specifications for lubricants for machinery, engines, cranes, weapons, cordage, heavy rolls (graphite greases), automobiles, extreme pressure (transmission) cutting oils are included with methods of testing, chiefly those in use in U. S. A. Conversion tables for viscosities, temps. and weights are presented. A. Guillaudeu

Melting point of solid greases. D. S. Velikovskiĭ, I. P. Lukashevich and F. L. Borshchevskaya. *Refiner Natural Gasoline Mfr.* **18**, 312-17(1939).—See *C. A.* **33**, 3126⁹. W. L. Benedict

Experimental studies on nonfluid lubrication. II. High-temperature reactions of addition agents. Acid effects and the mechanism of seizure. S. Kyropoulos. *Refiner Natural Gasoline Mfr.* **18**, 320-4(1939); cf. *C. A.* **33**, 8973⁷. W. L. Benedict

Function of colloidal graphite in special-purpose lubricating oils. Raymond Szymanowitz. *Natl. Petroleum News* **31**, R310, 42, 43(1939). W. L. Benedict

Dry distillation of wood, moss and similar materials. Hilding Bergstrom and K. G. Trobeck. *Tek. Tid.* **69**, Uppl. A-C, *Kemi* 49 52, 57–63, 67–71(1939)(English summary).—Tables are given showing the compn. of residues of various kinds of wood distd. with varying amts. of NaOH, NaOH + $Ca(OH)_2$, $Ca(OH)_2$ and $Ba(OH)_2$. The yield and compn. of the oils and water-sol. products were detd. Beechwood plus an equal weight of NaOH heated to 210° at ordinary pressures yields a water-sol. residue consisting chiefly of Na carbonate and the Na salts of org. acids. An addn. of 20 to 50% of NaOH increases considerably the yield of oil in dry distn. Addn. of lime to NaOH-treated wood increases the amt. of water-sol. products in the distillate. Otto Johnson

Continuous activation of refining clays (Blagodarov) **18**. High-pressure hydrogenation of low-temp. tar [re-processing of fractions of hydrogenated oil (Andō) **21**. Preventing corrosion of oil-well compressor tubes (Sheĭnin) **9**. Selection of greases for cold-rolling metals and alloys (Pavlov, Gallaĭ) **9**. Corrosion of valves in pumps used for deep-well pumping (Sheĭnin) **9**. Container for pouring out measured portions of lubricating oil (U. S. pat. 2,175,933) **1**. Preserving oxidizable substances [petroleum oils and their derivs.] (Brit. pat. 508,442) **13**. Treating liquid alkanes with SO_2 and Cl [for producing lubricating agents] (U. S. pats. 2,174,507-8-9) **13**. Extinguishing flames of gasoline (U. S. pat. 2,174,606) **24**.

Treating light petroleum distillates. Arthur Lazar and Thomas F. McCormick (to Tide Water Associated Oil Co.). U. S. 2,175,437, Oct. 10. A process employed involves treating a petroleum oil contg. aromatic hydrocarbons with sep. dosages of an aq. alk. soln. to remove org. compds. and of H_2SO_4 having a concn. less than 90% H_2SO_4 to remove nitrogenous bases, extg. the thus purified oil with a selective solvent whereby an ext. rich in aromatic hydrocarbons is obtained, sulfonating the ext. with H_2SO_4 of a concn. greater than 90% H_2SO_4, and recovering the sulfonated products.

Apparatus utilizing hot combustion gases for heating petroleum oils to effect cracking, etc. Arthur E. Nash and Franklin E. Shelly (to Alcorn Combustion Co.). U. S. 2,175,211, Oct. 10. Various structural and operative details.

Separating water-in-oil petroleum emulsions. Jesse V. Stevens. U. S. 2,174,849, Oct. 3. App. is described, and a method of sepg. a petroleum emulsion of water in oil comprising moving the emulsion against adjacent parallel oppositely rotating rolls whose surfaces are preferentially wettable by oil, squeezing the water from the emulsion by the adhesive action of the rolls on the oil, passing the oil by cohesion and adhesion through the rolls in a film on same and away from the water, and separately collecting the oil and water.

Breaking mineral-oil emulsions. Daniel Stryker (to The Texas Co.). U. S. 2,175,818, Oct. 10. Emulsions of the water-in-oil type are broken by use of an alkali metal salt of a sulfonated mineral oil and an alkali metal hexametaphosphate.

Demulsifying crude mineral-oils. Max Powell. U. S. 2,175,699, Oct. 10. Monoglycerol ricinoleate in a small proportion is used to effect demulsification.

Refining mineral oils with organic oxides. Ernst Teres, Josef Moos and Erich Saegebarth (to Edeleanu G. m. b. H.). U. S. 2,174,765, Oct. 3. A process of refining mineral oil contg. both high viscosity index hydrocarbons and low viscosity index hydrocarbons involves extg. the oil with a selective solvent of the class consisting of cyclic org. oxides contg. one O atom and less than 4 C atoms per mol., to form a raffinate layer contg. the high viscosity index hydrocarbons, and an ext. layer contg. the low viscosity index hydrocarbons of the mineral oil dissolved in the selective solvent, sepg. the layers from each other and recovering the solvent therefrom. Ethylene oxide or propylene oxide may be used as the selective solvent.

Dyes for mineral oils. I. G. Farbenindustrie A.-G. Brit. 508,483, June 30, 1939. Oil-sol. substances are obtained by heating $C_{10}H_8$, anthracene, phenanthrene, acenaphthene or mixts. thereof, in presence of an aromatic solvent, e. g., C_6H_6, toluene, xylenes, Ph_2, PhCl, cyclohexane, with anhyd. Al halides and leading air or O through the reaction mixt. The products dissolve in mineral oils with a red color and green fluorescence.

Noncracking distillation of mineral oils such as crude oils. Cecil F. Slawson (to Texas Co.). U. S. 2,175,817, Oct. 10. Various details of a 2-stage atm.-vacuum distn. app. are described, and of a method which comprises heating the oil in a continuously flowing stream and flashing without any substantial cracking thereof into a primary fractionating zone of substantial fractionating capacity, refluxing the vapors therein, removing lighter vapors overhead to suitable condensers, withdrawing an intermediate distillate cut which is fractionated to a narrow cut, such as a kerosene fraction, as a side stream to a stripping fractionating zone of lesser fractionating capacity into which no cut lighter than the intermediate distillate cut is introduced, withdrawing bottoms from the stripping fractionating zone, passing withdrawn bottoms in a continuously flowing stream through a heating zone, returning the heated bottoms to the stripping fractionating zone to supply heat thereto to redistil the side stream therein and sep. it from entrained heavy oil and impurities, fractionating the vaporized side stream and condensing the same within the stripping fractionating zone as a close distillate cut to sep. it from retained lighter constituents, removing the distillate cut as a side stream from an intermediate point of the stripping fractionating zone, and returning uncondensed vaporized lighter constituents from the stripping zone to the main fractionating zone.

Refining hydrocarbons such as crude benzene. Gerhard Rühl (to Koppers Co.). U. S. 2,175,619, Oct. 10. An arrangement of app. is described, and a process for refining crude benzene comprises evapg. the crude benzene and sepg. the vapors distg. over below about 80° and between about 125° and about 170° from those distg. over between about 80° and about 125°, subjecting only the sepd. vapors distd. off below about 80° and those above about 125° to the influence of a high-voltage electrostatic field in the presence of O and thereby converting the unstable unsatd. to more stable compds.; condensing the thus treated and the untreated vapors, and combining the con-

densed treated vapors with the condensed untreated vapors still untreated to convert unstable unsatd. to more stable compds.

Cracking hydrocarbon oils. Lyman C. Huff (to Universal Oil Products Co.). U. S. 2,175,397, Oct. 10. An arrangement of app. is described, and a process whch comprises charging crude oil through incondensable gases previously removed from the system, passing the oil, together with condensed portions removed from the gases, to a fractionator to combine reflux condensate therewith and to revaporize the condensed portions therefrom, passing the resultant mixt. to a heating zone wherein conversion conditions of temp. and pressure are maintained, discharging the resultant heated products into a reaction zone where liquids and vapors sep., subjecting the vapors to reconversion in a secondary heating zone, passing the reconverted products to a zone of reduced pressure, withdrawing the heavier, insufficiently converted components from the zone of reduced pressure, cooling the same, combining the cooled, insufficiently converted components from the zone of reduced pressure with heavier portions withdrawn from the reaction zone, commingling the resultant mixt. with the reconverted products withdrawn from the secondary heating zone prior to their introduction into the zone of reduced pressure, supplying vapors from the zone of reduced pressure to the fractionator for fractionation therein, finally condensing the fractionated vapors and sepg. resultant distillate from incondensable gases, and scrubbing the latter with the crude oil as aforesaid.

Cracking hydrocarbon oils such as crude or reduced crude oils. Helge C. Dieserud (to Texas Co.). U. S. 2,175,180, Oct. 10. An arrangement of app. is described, and a method of converting relatively high-boiling hydrocarbon oils into lower-boiling oils of the gasoline type which comprises heating in a coil a flowing stream of charging oil to dstn. temp. and discharging the heated charging oil into a sepg. zone wherein the oil seps. into vaporous and nonvaporous portions, withdrawing the vapors from the zone and subjecting them to vapor-phase cracking, discharging the cracked vaporous products from the vapor-phase cracking operation to an enlarged coking still, withdrawing nonvaporous portions from the sepg. zone and subjecting them in a coil to liquid-phase cracking, discharging the resulting cracked products directly into an independent distg. and fractionating zone, withdrawing vaporous products from the coking still and introducing them into the independent distg. and fractionating zone, withdrawing unvaporized residual liquid products from the independent distg. and fractionating zone and discharging them directly into the coking still wherein they are converted to coke by the contained heat of the vaporous cracked products passed thereto from the vapor-phase cracking operation, withdrawing reflux condensate from the independent distg. and fractionating zone and passing the condensate to the first-named coil for treatment in the system.

Cracking hydrocarbon oils such as reduced crude oils. Percival C. Keith, Jr. (to Gasoline Products Co.). U. S. 2,174,858, Oct. 3. An arrangement of app. is described, and a process for converting higher-boiling hydrocarbons into lower-boiling hydrocarbons which comprises sepg. cracked products produced as hereinafter specified into vapors and residue in a sepg. zone and passing resultant sepd. vapors to primary, secondary and tertiary fractionating zones in succession, maintaining superatm. pressure in the sepg. and fractionating zones, introducing heavy charging stock into the secondary fractionating zone whereby a portion of the vapors therein is condensed and a portion of the charging stock is vaporized, collecting resultant reflux condensate and unvaporized charging stock and passing the same to a cracking zone wherein the oil is subjected to cracking temp. to effect cracking and produce viscosity-breaking of the heavy constituents thereof, delivering resultant cracked and viscosity-broken products into the primary fractionating zone wherein sepn. of vapors from cracked residue occurs and resultant sepd. vapors are added to the vapors flowing to the succeeding fractionating zones, subjecting vapors in the tert. fractionating zone to fractionation to form a desired distillate product and reflux condensate, passing reflux condensate from the tert. fractionating zone to a second cracking zone wherein the condensate is subjected to cracking temp. under superatm. pressure to effect conversion into lower-boiling hydrocarbons, delivering resultant cracked products into the sepg. zone as the cracked products mentioned, passing resultant residue comprising residual constituents of cracking from the sepg. zone into a lower-pressure flash zone wherein sepn. of vapors from liquid residue takes place, passing cracked residue from the primary fractionating zone to a sep. lower pressure flash zone in which sepn. of vapors from liquid residue takes place, and combining vapors evolved in the first flash zone with vapors evolved in the second flash zone and subjecting the combined vapors to dephlegmation and condensation to form condensate.

Cracking hydrocarbon oils such as gas oil. Joseph K. Roberts, Jay H. Forrester and Roy J. Diwoky (to Standard Oil Co. of Ind.). U. S. 2,175,362, Oct. 10. An arrangement of app. is described, and a process of converting heavy hydrocarbon oils into gasoline and an intermediate-boiling furnace-oil fraction wherein the heavy hydrocarbon oil is subjected to cracking in a cracking zone and the products are sepd. from tar in an evapg. zone and thereafter fractionated under pressure in a fractionating zone from which gasoline vapor is withdrawn at the top, incompletely cracked hydrocarbons are condensed and withdrawn at the bottom whence they are recycled to the cracking zone, and an intermediate-boiling furnace-oil condensate contg. dissolved gasoline is withdrawn from an intermediate point of the fractionating zone. The process also comprises conducting the furnace-oil condensate to a second fractionating zone at lower pressure where dissolved gasoline is sepd. from the furnace-oil fraction, withdrawing and condensing gasoline vapors from the fractionating zone first mentioned and sepg. uncondensable gases therefrom, conducting the gasoline condensate to a third fractionating zone and sepg. substantially all the propane therefrom together with some butane and higher hydrocarbons, condensing the sepd. propane fraction and combining it with the gasoline fraction removed from the furnace-oil distillate sepd. in the second fractionating zone, conducting the combined gasoline and propane fraction to a fourth fractionating zone maintained at higher pressure than the second and third fractionating zones, and sepg. substantially all propane and lighter hydrocarbons from butane and heavier hydrocarbons in the fourth fractionating zone.

Cracking oils such as gas oil. Eugene C. Herthel (to Sinclair Refining Co.). U. S. 2,175,663, Oct. 10. An arrangement of app. is described, and a process which involves heating a stream of higher-boiling petroleum oil to a moderate cracking temp. under a substantial superatm. pressure and subjecting the higher-boiling oil to the moderate cracking temp. for a time sufficient to effect moderate cracking of the higher-boiling oil, sepg. the composite hot oil products of this heating operation into a vapor stream and a liquid stream and separately heating each of the sepd. streams to high-cracking temps. under maintained superatm. pressure, reducing the pressure on the composite hot oil products of each of these heating operations and simultaneously cooling them to temps. at which substantial cracking ceases, sepg. the expanded and cooled products into tar fractions and vapor fractions and recovering gasoline fractions from these vapor fractions.

Sweetening hydrocarbon oils. Geo. H. Von Fuchs and Lawson E. Border (to Shell Development Co.). U. S. 2,174,810, Oct. 3. Liquid hydrocarbon material such as a "sour gasoline" contg. mercaptans is treated at a temp. below 93° with metallic Cu in the presence of an effective proportion of added H halide gas such as HCl.

Superheating oil (such as that for producing motor fuel) in the vapor phase. Frank H. Praeger and Thomas B. Leech (to Alcorn Combustion Co.). U. S. 2,174,893, Oct. 3. Various details of app. and operation.

Refining hydrocarbon distillates such as cracked gasolines. Waldo C. Ault and Carroll A. Hochwalt (to Mon-

santo Chemical Co.). U. S. 2,174,908, Oct. 3. A catalytic method of treating liquid hydrocarbons of gasoline motor fuel boiling range which are rich in gum-forming constituents, to obtain a motor fuel of good quality and substantially free from gum, involves heating the liquid below cracking temp. while the liquid phase is maintained in the presence of an acid of P such as H_3PO_4 which is substantially nonvolatile at the temp. of the treatment, the heating being continued until the gum-forming constituents are converted to relatively high-boiling products which can be sepd. by distn., sepg. the liquid hydrocarbons from the acid of P, and subsequently effecting sepn. of lower-boiling from high-boiling hydrocarbons by fractional distn.

High antiknock motor fuel. Ernest A. Ocon. U. S. 2,175,359, Oct. 10. A method for producing isoaliphatic hydrocarbons suitable as high antiknock motor fuel comprises treating oxygenated derivs. of straight-chain aliphatic hydrocarbons including alcs. and fatty acid in about the gasoline boiling range with an alkali compd. capable of saponifying fatty acids among such derivs., causing the thus treated mixt. to react with a reducing gas composed of H and CO in the presence of a catalyst with relatively high hydrogenating and low dehydrating activity at a temp. of about 315–480° at super-atm. pressure and with a space velocity of about 75 to 200 cu. ft. per hr. per cu. ft. of catalyst, fractionating vapors from this catalytic reaction to obtain an overhead of motor-fuel ingredients, and condensing such motor-fuel ingredients.

Pump and associated devices for delivery of liquids, such as Diesel engine fuel oil, under high pressure. Ernest V. Parker. U. S. 2,174,526, Oct. 3. Various structural and operative details.

Recovering liquefiable hydrocarbons from strata penetrated by wells. Jay P. Walker and Edwin V. Foran (to Eureka Process Co.). U. S. 2,174,336, Sept. 26. App. is described, and a method of recovering liquefiable hydrocarbon constituents from a gaseous reservoir in which they are in soln. with natural gas and are under high pressure within the retrograde condensation range which includes, flowing the gas from the well under high pressure within the retrograde condensation range, cooling the gas while the pressure is maintained substantially within the retrograde condensation range to condense liquefiable hydrocarbon constituents, sepg. the gas from the liquids at a high pressure substantially within the retrograde condensation range, raising the pressure of the high-pressure degraded gas only sufficiently to return it to a high-pressure gaseous reservoir, and returning the repressured gas to a gaseous reservoir through an input well and employing the returned gas to displace the gaseous products in the reservoir en masse toward the output well for prolonging high-reservoir pressures.

Treating wells penetrating calcareous earth formations. Willard H. Dow (to Dow Chemical Co.). U. S. 2,175,079, Oct. 3. A method of treating a well such as an oil or gas well penetrating a calcareous earth formation to facilitate production involves introducing into the well a charge of an aq. soln. of a weak acid such as chloroacetic acid, having an ionization const. between 8.59×10^{-5} and 1.55×10^{-3} and applying pressure to the charge to force it into the formation.

Treating wells such as oil, gas or brine wells with hydrochloric acid to increase production. Sylvia M. Stoesser (to Dow Chemical Co.). U. S. 2,175,095, Oct. 3. For preventing pptn. of gelatinous Fe and Al hydroxides in the spent acid soln., there is introduced into the well an aq. HCl soln. contg. about 0.5–10% of glycine or lactic, citric or glycolic acid, and pressure is applied to force the soln. into the formation under treatment.

Use of acid in wells such as oil, gas or brine wells to increase production. John J. Grebe (to Dow Chemical Co.). U. S. 2,175,081, Oct. 3. A strong inorg. acid such as HCl soln. contg. SO_2 is introduced into the well.

Intercepting oil-well-casing gases during welding operations. Earl G. Summers. U. S. 2,175,137, Oct. 3. A method of intercepting gas in the casing of an oil or gas well while the proximate terminals of the inner casing pipes are welded involves internally sealing the inner casing of the well and sealing the space between the inner and outer casings, both seals being below the zone of the welding operation.

Paraffin scraper suitable for use in oil-well tubing. Sidney V. Dodson. U. S. 2,175,770, Oct. 10. Various structural details.

Dewaxing oils such as mineral lubricating oil fractions. Lyle Dillon and Claude E. Swift (to Union Oil Co. of Calif.). U. S. 2,174,938, Oct. 3. An arrangement of app. is described, and a process which comprises shock chilling the oil to ppt. wax, subjecting the chilled oil contg. pptd. wax to the influence of an elec. field between electrode surfaces immersed in the oil to render the wax readily separable, and sepg. the wax from the chilled mixt. by electrodeposition upon an immersed electrode surface. Cf. *C. A.* **33**, 5174[7].

Lubricating composition for use in metal-working operations such as cold rolling or drawing. Stanley P. Waugh (75% to Tide Water Associated Oil Co.). U. S. 2,174,907, Oct. 3. A mineral oil and the sapond. product derived, as by the action of triethanolamine, from the fatty acid mixt. obtainable from a palm oil are used together in a substantially neutral aq. emulsion.

Lubricating and dielectric oil compositions. Frank M. Clark (to General Elec. Co.). U. S. 2,175,877, Oct. 10. A mineral oil or a vegetable oil such as a castor-oil mixt. or a chlorinated biphenyl mixt. is used contg. 25–50% of an alkyl phosphate ester the alkyl radical of which contains not more than 4 C atoms, such as triethyl or tributyl phosphate, which gives a lowered viscosity which is relatively uniform at various low temps.

"Beneficiating" lubricating oils. John M. Musselman and Herman P. Lankelma (to Standard Oil Co. of Ohio). U. S. 2,175,548, Oct. 10. About 0.001% or more of diphenyl carbazide or diphenyl semicarbazide is added to a lubricating oil such as one for internal-combustion engines in order to inhibit degradation in use at high temps.

Apparatus for reclaiming used lubricating oil (such as that from automobile engines) by heating and filtration under pressure. Carl E. Holt. U. S. 2,174,265, Sept. 26. Various structural and operative details.

Oil filter with a transparent casing for inspection of the oil. Lyall B. White. U. S. 2,174,769, Oct. 3. Various structural details of a device suitable for use with lubricating systems of the pressure type.

Device (with intermeshed gears) for demonstrating the viscosity characteristics of lubricants. Frederick G. Rau. U. S. 2,175,638, Oct. 10. Various structural and operative details.

Increasing the melting point of petroleum asphalt, etc. James E. Gambrill (to Atlantic Refining Co.). U. S. 2,175,189, Oct. 10. The material is mixed with NaOH 0.5–10% and the mixt. is heated to about 315–370° (suitably for 15 min. to 8 hrs.).

23—CELLULOSE AND PAPER

CARLETON E. CURRAN

Microscopic analysis of swelled cellulose. B. G. Milov. *Bumashnaya Prom.* **17**, No. 9, 7–14(1939).—Shake a cellulose sample contg. 0.17 g. abs. dry fibers with 7 cc. water in a stoppered vessel until the lumps disappear, add 7.15 cc. Cu-NH_4 soln. contg. 14 g. Cu and 195–210 g. NH_3/l., mix the contents, shake for 10 min., and withdraw a 2-mg. portion with a pipet and use 1–2 drops thereof for microscopic study. B. Z. Kamich

Lignin. XXVI. A stilbene derivative from the sulfite waste liquor. Hermann Richtzenhain and Christian v.

Hofe. *Ber.* **72B**, 1890–2(1939); cf. *C. A.* **33**, 9290⁹.—In repeating the work of Hibbert and coworkers (*C. A.* **32**, 3314⁷, and earlier papers) who, by heating the waste sulfite liquor from spruce wood with alkali, obtained about 7% vanillin (based on the lignin in the liquor), the authors obtained a further product (I) which gave vanillin on cautious oxidation and proved to be 3,3′-dimethoxy-4,4′-dihydroxystilbene. For unknown reasons the yield varied widely; in the most favorable cases it was about 1% of the lignin but in others it amounted only to traces or none at all. As I is not present before the boiling with alkali it is probably formed during the operation from some constituent of the waste liquor. This is apparently not the vanillin formed simultaneously, for vanillin alone yields no stilbene with sulfite and alkali under these conditions. The yield seems to be best when on treatment of the liquor with alkali appreciable amts. of free S appear. The liquor was heated with alkali under pressure (U. S. pat. 2,069,185, *C. A.* **31**, 1828²), then acidified with H_2SO_4, the liberated SO_2 boiled off, the filtered soln. extd. with ether, the vanillin removed from the ext. in the usual way, the soln. evapd., the residue extd. with acetone, the acetone evapd. and the product crystd. from alc. I m. 212–13°; *4,4′-di-Me ether*, prepd. with alk. Me_2SO_4, faintly yellow, m. 153°; *4,4′-diacetate*, m. 226°, is hydrogenated in AcOH with Pd-$BaSO_4$ to *3,3′-dimethoxy-4,4′-diacetoxybibenzyl*, m. 140–1°, which is sapond. by 10% NaOH to the *4,4′-di-HO compd.*, m. 158. I was synthesized for comparison by distg. trithiovanillin with Cu powder, and its di-Me ether by distg. thioveratraldehyde with Fe powder. This ether with $KMnO_4$ in acetone gave veratric acid, m. 181°. C. A. R.

Study of break-down products of lignin. P. A. Bobrov and L. I. Kolotova. *Compt. rend. acad. sci. U. R. S. S.* **24**, 49–51(1939)(in English).—The present paper reports further work on the oxidation products of lignin (cf. *C. A.* **32**, 3955⁶). The Ba salts of the hydroxy acids were evapd. and recrystd. giving a product of const. compn. contg. 53.43% Ba. This amt. corresponds to that in tartronic acid salt (53.8% Ba) and leads to the conclusion that lignin is of carbohydrate nature. Four g. of Ba salts was caused to react at 170–180° for 4 hrs. in sealed tubes with 30 ml. HI (sp. gr. 1.19) and 1.4 g. red P. The mixt. was dild. with 3 vols. of H_2O and extd. with Et_2O. The residue left after distg. off the Et_2O was treated with 25% H_2SO_4 and Zn dust in the cold and filtered. The filtrate was treated with $PbCO_3$ and Ag_2O. It was then acidified and extd. wth Et_2O. The residue had a characteristic odor of fatty acids. It was distd. into 4 fractions: (1) below 125°; (2) 125–165°; (3) 165–185° and (4) 185°. The Na salts of each of the fractions were converted into their *p*-bromophenacyl esters and recrystd. Fraction (1) was thus identified as AcOH, (2) and (3) were identified as butyric acid and (4) was identified as caproic acid. Glycolic acid was identified among the nonvolatile products of reduction. Lignin was also oxidized with 20% H_2O_2 at room temp. in the presence of 2 *N* NaOH. On acidification of the aq. soln. a voluminous white flaky ppt. was obtained in a yield of 54–60% of the oxidized lignin. The H_2O-sol. acids were similar to those obtained by the oxidation in neutral medium. The white ppt. gradually turned black on standing and lost its soly. in hot H_2O, MeOH, EtOH, AcOH, Me_2CO, and similar solvents. It could finally be dissolved only in aq. NaOH but regained the initial soly. characteristics on pptn. from its alk. soln. The substance was purified by repeated pptn. It melted with decompn. and gave a reaction for furane when heated. Na and Ba salts were obtained. The Br deriv., prepd. by bromination in glacial AcOH soln. or of its Na salt in aq. soln., was sol. in MeOH, EtOH and in EtOAc. The substance had the following ultimate analyses: C 57.39, H 5.16 and OCH_3 9.71%. The empirical formula is $C_8H_8O_4$. Mark Plunguian

Softening of water in the production of rayon. V. S. Burlakov. *Legkaya Prom.* **1938**, No. 2, 106–17; *Khim. Referat. Zhur.* **2**, No. 1, 110(1939).—A combination scheme can be used for softening water: permutite treatment with a preliminary liming. This arrangement gives light, clear water contg. a min. amt. of impurities, and having a hardness of 0.1–0.2°. W. R. Henn

Manufacture of pulp from bagasse. I. Bagasse pulp by soda process. Syosuke Tanaka and Muneo Koriyama. *J. Agr. Chem. Soc. Japan* **14**, 724–32(1938); cf. *C. A.* **34**, 261⁸.—Bagasse pulp was prepd. by the soda process; fresh and 1.5-year-old bagasse was used. New bagasse gave about 17% more pulp than old. Lignin can be removed very easily by the soda process. α-Cellulose in the old bagasse increased up to 85% when both the alkali content and pressure were increased; with new bagasse there was a max. yield of 73%. The pentosan content for the new-bagasse pulp was 26–31%, while it was only 7–10% for the old-bagasse pulp. There was about a 2–6.5% reduction in pulp during the process of bleaching. The optimum conditions for the manuf. of pulp for the new bagasse are: alkali 24%, steam pessure 2.5 atm.; for the old bagasse, alkali 24% and steam pressure 6 atm. F. I. Nakamura

Mechanism of pulp bleaching. F. P. Komarov. *Bumazhnaya Prom.* **17**, No. 8, 3–9(1939).—A review of the literature. It is concluded that in the preliminary bleaching with gaseous Cl_2 the process of chlorination prevails while in using hypochlorite the oxidation reaction predominates. Seventeen references. B. Z. Kamich

Rapid methods for determining the viscosity of pulp. F. P. Komarov. *Bumazhnaya Prom.* **17**, No. 9, 3–7 (1939).—Various methods for the rapid detn. of the η of pulp are discussed. The need for a single satisfactory method is emphasized. B. Z. Kamich

Strong acid liquor for sulfite pulping. N. N. Nepenin. *Bumazhnaya Prom.* **17**, No. 6, 3–5(1939).—Polemic on Giller's paper (*C. A.* **33**, 857⁷). B. Z. Kamich

Regeneration of sulfur dioxide at the Balakhnin sulfite cellulose plant. I. A. Nagrodskii. *Bumazhnaya Prom.* **17**, No. 7, 10–14(1939).—It is proposed to recover the SO_2 at the Balakhnin sulfite cellulose mill by a combined hot cold method in which the SO_2 is absorbed in cold acid followed by heating of the acid in a tank. The system includes 2 500-cu. m. tanks of high and medium pressure which operate successively. Before the tanks the discharge gas passes through eductors which operate on the principle of injectors. Acid enters the upper section of the eductor at a pressure of about 10 atm. while the discharge gas enters through a side pipe. The gas is well absorbed in the eductor. Flowsheet is given. B. Z. Kamich

Biological experiments with sulfite pulp waste liquor. A. O. Winter. *Finnish Paper Timber J.* **21**, 636–7(in English)(in Finnish, 646–52)(1939).—The formation of H_2S from sulfite waste liquor occurs only if the contaminated water is in the anaerobic state, and contains no SO_2 or other S compds. or sugar. Neutralization of the SO_2 with $CaCO_3$ gives rise to H_2S if the temp. is above +10°, the concn. of the waste liquor is 1.40–1.800 and the pH is between 4.6 and 7.2. Microörganisms may reduce inorg. sulfate, thiosulfate, sulfite and lignosulfonic acid to H_2S by using the biol. decompn. products of glucose, arabinose and xylose as sources of energy. Preservation of the aerobic state of the water course by lowering the O demand or pumping in addnl. water contg. O is not always satisfactory for preventing H_2S formation. Fermentation of the liquor for EtOH manuf. is ineffective since only glucose is removed. Moreover, the SO_2 is neutralized and yeast is added, resulting in strong H_2S formation. Removal of 75% of the S compds. with $Ca(OH)_2$ and reduction of the O demand by 70–80% (G. Howard, *Paper Mill* **59**, No. 31, 11(1936)) has no effect on the availability of the sugars to the microörganisms since this waste liquor readily forms H_2S. The purification of the waste liquor by preliminary biol. formation of H_2S to remove hexoses, pentoses and S compds. is impractical since the fermentation requires 3–4 weeks, and a dilu. of the liquor of 1:50. S. A. Karjala

Hydrogenation of waste sulfite liquors. P. A. Bobrov and L. I. Kolotova. *Compt. rend. acad. sci. U. R. S. S.* **24**, 46–8(1939)(in English).—Sulfite waste liquor acidified with H_2SO_4 was steam treated at 100° and then evapd. to dryness. This served to remove half of the fixed S as SO_2. This preliminary treatment led to a considerable saving of

H. The yield of the initial material was 70.5% of the wt. of dry residue obtained by direct evapn. The initial material was suspended in heavy hydrogenation oil in a proportion of 2.1. Consumption of H is first observed at the temp. range 140–170°. During further heating to 300°, the consumption of H_2 is inappreciable but appears again at temps. over 300°. High yields of heavy oils in almost complete absence of light fractions were obtained at temps. not over 340-350°, while a sharp increase in light fractions, b. below 150°, was obtained by raising the temp. above 400°. By heating for 6 hrs. at 350–450° a total yield of 55% oils was obtained. The yield of light fractions was 10% of the total amt. of oil. At temps. below 350° the yield of light fraction was not more than 8% of the oil. There was 18% of solid carbonaceous residue left after hydrogenation with an ash content of 50%. It is argued that wood, lignin, cellulose, wood-distn. tars and other products break down at temps. of 270-280°. Thermal decompn. is accompanied by a considerable evolution of H_2O, CO_2, CO, etc. The loss of fixed O lessens the consumption of H. Destructive hydrogenation must be preceded by thermal decompn. while controlled hydrogenation, such as reduction of OH acids into fatty acids, must be carried out at temps. below those of thermal decompn.

Mark Plunguian

Viscosity of paper as a criterion of pulp quality. E. V. Lipshits. *Bumazhnaya Prom.* **17**, No. 8, 10–17(1939).— Tabulated and graphical data are given on the relation of viscosity to (1) aging of paper, and (2) mech. properties and ease of grind of sulfite and sulfate pulps during various stages of bleaching with Cl_2. The η varied inversely with the duration of bleaching, the Cu nos. increased almost linearly, the content of α-cellulose decreased and reached a min. after 4 hrs., resistance against break decreased sharply at first but after 3 hrs. it reached an almost min. value, and the tensile strength increased during the first hr., then it dropped to nearly the original value in 3 hrs. and after that it changed very little. Conclusion: Bleaching produces parallel decrease in η, difficulty in grind and resistance to break. B. Z. Kamich

Calculating the dirt particles in paper. Kh. A. Frukhtbein. *Bumazhnaya Prom.* **17**, No. 7, 15–19(1939).— Various methods for calcg. the dirt particles in paper are briefly reviewed. The method of Clark is considered more accurate than the present Russian method. B. Z. K.

Chloromethyl compds. of sulfonamides [for treatment of paper] (Brit. pat. 508,794) **13.**

Cellulose. Henry Dreyfus. U. S. 2,175,257, Oct. 10. A material such as chips of poplar or spruce is subjected to the action of an alk. soln. of alky. equiv. to that of a 2.5–10% NaOH soln. at a temp. which is initially at least 120° and which rises as the treatment proceeds by 3–7° per hr. to between 155° and 180°.

Acetylating cellulose. Pierre Koetschet (to Soc. des usines chimiques Rhône-Poulenc). U. S. 2,175,842, Oct. 10. In the manuf. of fibrous acetylated cellulose, cellulose such as bleached linters is pretreated with HOAc and is then treated with an acetylating mixt. contg. Ac_2O, HOAc, a substance such as benzene which prevents the cellulose acetate from going into soln., and a catalyst free from metallic salt and which consists of a mixt. of perchloric acid with 2-20% its wt. of H_2SO_4.

Cellulose ethers. I. G. Farbenindustrie A.-G. Brit. 508,517, June 30, 1939. Materials sol. or capable of swelling in H_2O but insol. in org. solvents are produced by etherifying pretreated wood with monohaloacetic acids or their salts, e. g., monochloroacetic acid or its Na salt. The wood is pretreated with NaOH soln. at normal or increased pressure so that the lignin, pentosan and resin constituents are not substantially removed.

Cellulose esters. Ernst Berl. U. S. 2,175,103, Oct. 3. For producing a partially esterified product, wood pulp is treated with formic acid and the resulting product is further treated with a lower aliphatic acid (such as for acetylation) with use of an acid catalyst and of an anhydride to form a tri-substituted cellulose ester and the latter is dissolved by heating it with a concd. lower aliphatic acid such as formic acid in the presence of a salt of a weak acid such as borax capable of reacting with the residual acid catalyst. Various examples with details are given.

Mixed cellulose esters such as cellulose acetate methacrylate. Robert W. Maxwell (to E. I. du Pont de Nemours & Co.). U. S. 2,175,357, Oct. 10. A cellulose deriv. such as acetone-sol. cellulose acetate which is sol. in org. solvents and contains esterifiable hydroxyl groups is dissolved in a solvent such as acetone which is substantially inert to the esterifying agent, and then treated with an esterifying agent such as methacrylic anhydride with use of a catalyst such as NaOAc or other alkali or alk. earth metal carbonate, phosphate, acetate, butyrate or borate in at least sufficient proportion to react with the acid set free in the esterification.

Cellulose derivatives. The Dow Chemical Co. Brit 508,766, July 5, 1939. Alkali cellulosate is obtained by causing anhyd. cellulose to react with an alkali metal amide in liquid NH_3 at below 25° under the vapor pressure of the NH_3 at the temp. employed, the reaction being conducted in the absence of H_2O. Mono-, di- or tri-alkali cellulosate is obtained according to the proportion of alkali amide present. During the subsequent etherification of the alkali cellulosate, an org. solvent, e. g., C_6H_6, toluene, xylene, may be present. In an example, Na and $Fe(NO_3)_3$ are added to liquid NH_3 in a closed vessel and the mixt. is stirred until the blue color disappears, finely divided anhyd. cellulose is added and the mixt. is stirred for several hrs. while NH_3 is allowed to distil off slowly until at the end of the reaction only enough liquid remains to wet the mass, the mixt. is then cooled below −33° and EtBr and toluene are added, the mixt. is allowed to stand for several hrs., the temp. rising gradually to 25°, the mixt. is then poured into hot H_2O and the ethylcellulose is sepd. from the aq. suspension by extn. with a solvent.

Crimped yarns of cellulose derivatives such as cellulose acetate. Donald Finlayson (to Celanese Corp. of America). U. S. 2,174,573, Oct. 3. Yarns such as those having a basis of cellulose acetate are subjected to the operations of twisting, setting the twist, and untwisting, and subsequent treatment in a bath of hot aq. liquid to impart a higher degree of crimp.

Crinkled decorative material such as that of regenerated cellulose films. Eleanor R. Cohoe. U. S. 2,176,019, Oct. 10. A film of material such as one of regenerated cellulose or a cellulose ester or ether or gelatin is subjected to the action of a softening agent, twisted into a substantially cylindrical compact mass, subjected to such tension as to produce plastic deformation resulting in the formation of a multiplicity of permanent, fine and irregular wrinkles in the material, and is then untwisted.

Soda treatment and conversion of cellulose-fiber sheets. George A. Richter and Kenneth E. Glidden (to Brown Co.). U. S. 2,174,894, Oct. 3. A dry cellulose-fiber sheet such as one of bleached sulfite pulp is dipped in water until satd., then dipped in NaOH soln. of about 18% strength at about room temp. to effect replacement of the water by the NaOH soln., pressed to a predetd. NaOH content, and treated, as by shredding and xanthation, to convert the soda-cellulose of the sheet into another cellulose deriv.

Extruded tubing of nitrocellulose composition. Frank H. Reichel and Augustus E. Craver (to Sylvania Industrial Corp.). U. S. 2,175,313, Oct. 10. Tubing suitable for sausage casings is formed by extruding a cellulose nitrate compn. contg. about 6–11% of water, with coagulation in an aq. bath.

Treating artificial filaments, films, sheets, etc., with liquids. Atlas Powder Co. Brit. 508,682, June 30, 1939. Regenerated cellulose material is plasticized, softened and conditioned by treating with a soln. of sorbitol sirup contg. a relatively large proportion of sorbitol (I) and, in addn., substantial proportions of each of saccharitols, i. e., alcs. corresponding to saccharinic acids, Na salts of hydroxycarboxylic acids contg. 4–6 C atoms, tetrahydric alcs. and monoanhydrohexitols, and allowing the material to dry.

The treatment may be conducted during or subsequently to the production of the regenerated cellulose material. The sirup may also contain small amts. of unreduced sugar, mannitol, and Na_2SO_4. The Na salt of a hydroxycarboxylic acid may be a lactate or saccharinate. Brit. 508,519, June 30, 1939, divided on 508,682, claims a *softening* or *conditioning agent* or *compn.* comprising I, saccharitols, Na salts of hyroxycarboxylic acids, tetrahydric alcs. and monoanhydrohexitols. The several ingredients of the compn. may be brought together by mixing, or the mixt. may be obtained by reduction of glucose and treatment of the reduced liquor so as to recover therefrom a viscous aq. sirup contg. the desired ingredients. The compn. is insol. in hydrophile solvents with but few exceptions among which are AcOH, pyridine, PhOH and $AcNH_2$.

Rayon staple. Henry C. Forrest. U. S. 2,174,576, Oct. 3. App. is described and a method of making a spinnable rayon staple, which comprises extruding a cupro-ammonium cellulose soln. into a pptg. bath to produce a wet cupro-ammonium regenerated cellulose filament, subjecting the filament to treatment with liquids while setting up irregular strains in the filament by stretching and then relaxing the strains to deform the filament and drying the filament in slack condition permitting free shrinkage to retain the deformation, and so feeding and guiding the filament during such treatment that it is free from folding.

Rayon, etc. Aktiengesellschaft für Vermögensverwertung. Brit. 508,781, June 26, 1939. Rayon, spun fibers and horsehair and also bands, films, etc., are prepd. from alk. solns. of phosphoproteins or conjugated proteins to which have been added satd. or olefinic unsubstituted aliphatic carboxylic acids having 3-9 C atoms, or their derivs. such as esters or amides, with or without aliphatic amines or amino acids. Acids specified are propionic, heptylic, caprylic and caproic, and amines are $PrNH_2$, allylamine and $BuNH_2$. A small quantity of CS_2 may be added. In an example, potash lye is added slowly to a paste of acid casein and CS_2, propionic acid and $PrNH_2$ are added, the soln. is then spun into a pptg. bath and the thread is dried under tension and hardened in a formalin bath.

Drying reel for rayon thread. Louis E. Lovett (to Industrial Rayon Corp.). U. S. 2,175,205, Oct. 10. Various structural, mech. and operative details.

V-type bedplate for paper-pulp beaters. Archer L. Bolton (to John W. Bolton & Sons, Inc.). U. S. 2,174,774, Oct. 3. Various structural details.

Treating fibrous material as in the production of sulfite pulp from wood chips. Albert D. Merrill (to Chemipulp Process Inc.). U. S. 2,175,154, Oct. 3. An arrangement of app. is described, and a method of treating fibrous material which comprises soaking the material in a recirculating mass of hot alk. liquor; then draining the excess liquor and soaking the material in a recirculating mass of acid liquor maintained at elevated but below reaction temps. and then raising the temp. and cooking the material in the acid liquor.

Apparatus for pressing moving webs in papermaking machines. Harold S. Hill. U. S. 2,174,744, Oct. 3. Various structural and operative details of an app. in which water or air under pressure exerts pressure on an impervious belt which may be formed of rubber, impregnated canvas or thin steel and which serves to confine a paper web as it passes over a roll.

24—EXPLOSIVES AND EXPLOSIONS

C. G. STORM

Dynamite in an automobile plant. A method of blasting drill bits from crankshaft oil holes. O. J. Otto. *Explosives Engr.* **17**, 376(1939).—When an oil-hole drill breaks off in the crankshaft, $^1/_8$–$^1/_2$ a thimbleful of 40% ammonia gelatin dynamite is pushed down the hole and a cap and fuse are placed on the dynamite. The charge is fired, and the drill piece will then fall out on tapping with a hammer. Caliper measurements have failed to show any enlargement of the hole and exhaustive tests have shown no damage to the grain structure or other specifications of the crankshaft steel. E. M. Symmes

Explosives suitable for detonation. Willard de C. Crater (to Hercules Powder Co.). U. S. 2,174,914, Oct. 3. Ingredients used together may comprise charcoal 8, S 7, and nitrated balsa wood contg. about 9-11.5% N 10, impregnated with NH_4NO_3 10 and $NaNO_3$ 65 parts. Various similar mixts. are described.

Explosives such as ammunition priming mixtures. Willi Brün (to Remington Arms Co.). U. S. 2,175,826, Oct. 10. An explosive compn. is prepd. by moistening (without completely dissolving) a mixt. of a nitrate of Pb or Ca with a hypophosphite of K, Na, Ca, Sr, NH_4, Ba or Mn.

Treating deteriorated nitrocellulose for smokeless powder manufacture. Fredrich Olsen, Gordon C. Tibbitts and Edward B. W. Kerone (to Western Cartridge Co.). U. S. 2,175,212, Oct. 10. Deteriorated nitrocellulose contg. regions of acid concn. is softened with a solvent such as EtOAc which is immiscible with water, and the material is washed in a bath of water.

Electric blasting initiator of the delay type. Lawton A. Burrows and Wm. F. Filbert (to E. I. du Pont de Nemours & Co.). U. S. 2,175,249, Oct. 10. An ignition charge, in the form of a bead surrounding the bridge wire, comprises a complex salt of Pb nitrate with a Pb salt of a nitrophenol such as a bis basic Pb picrate.

Extinguishing flames of gasoline, etc. Xavier B. Tansill. U. S. 2,174,606, Oct. 3. A method of extinguishing the flames on the surface of a body of burning oil, gasoline, benzine, naphtha, kerosene, etc., comprises submerging a plurality of bodies of solid CO_2 in the body of burning liquid fuel so that CO_2 gas resulting from sublimation bubbles to the surface of the burning fluid and forms an atmospheric excluding blanket on the surface.

25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

A theory of the color of dyes. Linus Pauling. *Proc. Natl. Acad. Sci. U. S.* **25**, 577-82(1939).—The long-wave absorption band of a dye is assocd. with the resonance of a pos. charge from atom to atom about the mol. The source of the resonating pos. charge may be the CO group

as in benzaurin and indigo, or the —N:O, O—N:O and —N:N— groups for nitroso, nitro and azo dyes. In some cases the resonating charge results from external ionization as in Dobner's Violet. The band of longest wave length, representing the transition from the normal state with nodelesswave function to the excited state with a single nodal plane is predicted to be the most intense band for many dyes. The agreement between predicted and observed values is good. Detailed accounts are to be published. Janet E. Austin

Soluble chromium derivatives of dyestuffs. James L. Boyle. *Am. Dyestuff Reptr.* **28**, No. 24, *Proc. Am. Assoc. Textile Chem. Colorists* P746-51(1939).—The development, from a chem. standpoint, of sol. metallic derivs. of mordant dyestuffs which makes possible a substantive dyeing process requiring no mordant complexes of azo

dyestuffs is reviewed and the behavior of metallic complexes in dyeing outlined. The class of dyes most used from the production of sol. metallic derivs. is the *o*-substituted azo mordant dyes. W. H. Boynton

The management and operation of a hosiery dye house. A. G. Alexander and Clarence Wille. *Am. Dyestuff Reptr.* 28, No. 25, *Proc. Am. Assoc. Textile Chem. Colorists* P716-21(1939).—The arrangement, the dyeing equipment, the method of dyeing silk hosiery, methods for mercerizing hosiery, methods for wool hosiery, types of goods, water-supply materials and purchases, steam and power supply and controlling and recording app. are discussed. W. H. Boynton

Organizing a dyeing and finishing plant for synthetic piece goods. P. J. Wood. *Am. Dyestuff Reptr.* 28, No. 26, *Proc. Am. Assoc. Textile Chem. Colorists* P746-51 (1939). W. H. Boynton

Technical dyeing methods. II. C. L. Wall. *Textile Mfr.* 65, 454(1939); cf. *Ibid.* 411.—Limitations in adsorption methods of dyeing and the possibilities of continuous impregnation processes are discussed, and some requirements are given. Agents which assoc. with ionic groups of dyestuffs, thus preventing adsorption, are a means of improving the application of existing dyestuffs by simple impregnation. Pyridine, etc., can be used to advantage in the application of anionic dyestuffs (if the fumes are disposed of properly). Halsey E. Silliman

Protective coatings for the wooden parts of dyeing equipment. L. K. Tyumenev. *Shelk* **1938**, No. 5, 41–2; *Khim. Referat. Zhur.* 2, No. 2, 134(1939).—Bakelite lacquers can be used for protection of the wooden parts. The lacquer is applied to the wood heated to 85–90°, dried and second coat applied. Good results were obtained with the acidic ("novolak") as well as with the basic lacquers ("rezol"), although the acidic lacquer has a somewhat unpleasant odor and is less stable to bases. W. R. Henn

Textiles of tomorrow. Kenneth H. Barnard. *Am. Dyestuff Reptr.* 28, 737–41(1939).—An address. W. H. Boynton

The new artificial textiles. G. Martin. *Bull. soc. ind. Rouen* 66, 319–36(1938).—An address. C. R. P.

Refractive indexes of textile fibers: double variation method for their determination. Kenneth R. Fox. *Textile Research* 10, 79–93(1939).—The method and app. employed to secure a more precise and convenient method of measuring the refractive indexes of individual textile fibers are outlined. Refractive indexes of standard immersion fluids are shown, also curves giving temp. increase vs. heater scale reading, the effect of temp. on refractive indexes, the effect of wave length on them, and a sample of the data taken in test detns. and a measure of the dispersion in each table. Eight references. W. H. B.

The hydrophobing of artificial fibers and fabrics. Richard Flint. *Silk and Rayon* 13, 808, 834(1939).—A discussion of the nature of the chem. process of hydrophobing and of methods for hydrophobing pieces of cloth. Milton Harris

Properties and utilization of "Teca" staple fiber. Harold DeWitt Smith. *Rayon Textile Monthly* 20, 637–8, 639(1939).—See *C. A.* 33, 9628[4]. *Ibid.* 699–701. Drawing machines, slubbers, intermediates, speeders and spinning frames handle Teca satisfactorily. The conversion of Teca yarns into fabrics is outlined, also the dyeing and finishing. W. H. Boynton

The chemistry of ramie fibers; a method of degumming and analysis of the raw and degummed materials. Lilly Gomez and Isabel Concepcion. *Univ. Philippines Nat. and Applied Sci. Bull.* 7, 33–7(1939).—Uhi Hakucho ramie fibers from Davao, Mindanao, were heated under 15 lb. pressure for 1½ hrs. with a soln. composed of 2% soap and 0.2% palm oil, then bleached with 0.5% NaOCl soln. The white fibrous material obtained was treated under 10 lb. pressure for ½ hr. with a 1% soln. of $Na_2S.9H_2O$, then bleached again with 0.1% NaOCl soln. The degummed fiber, obtained in 80% yield, was soft, lustrous, strong, contained no lignin, was composed mostly of α-cellulose, and had greater dyeing capacity than cotton. Analyses of the raw and degummed materials are included. George Ayers

The use of sodium hexametaphosphate in the silk industry. K. M. Markuze and M. N. Vasil'eva. *Shelk* **1938**, No. 5, 28–32; *Khim. Referat. Zhur.* 2, No. 2, 116(1939).—Exptl. washings of silk in the presence of $(NaPO_3)_6$ showed that the fat content of the fibers was decreased, the time of washing reduced and the formation of Ca soap prevented. The use of $(NaPO_3)_6$ in indanthrene dyeing is of some practical interest. W. R. Henn

New knowledge of the physics and microscopic structure of wool. Werner Von Bergen. *Textile Research* 10, 63–9(1939).—A review. W. H. Boynton

The processing of linen piece goods in the United States. O. W. Clark. *Am. Dyestuff Reptr.* 28, 709–14, 727–9 (1939).—Const. and meticulous supervision must be employed in the processing of linen fabrics. Each quality of linen fabric requires its own set of dyeing formulas. Detailed formulas and step-by-step procedures are given for the processing of various types of linen fabrics. W. H. B.

Bleaching of linen with peroxide. O. E. Itina. *L'nopen'ko-dzhutovaya Prom.* **1938**, No. 4, 35–44; *Khim. Referat. Zhur.* 2, No. 1, 97(1939); cf. *C. A.* 33, 9002[5].—A soln. of Na_2O_2 in water was neutralized by the addn. of H_2SO_4. The optimum concn. of the peroxide for bleaching linen was 1.5–2% of O on the wt. of the cloth. Best results were obtained from bleaching at 80–5° for not less than 3 hrs., or for 1 hr. at 80° and 1 hr. at 100°. A stabilizer (Na silicate) must be added to the peroxide soln. The optimum alky. was obtained with a ratio in the bleaching soln. of SiO_2 (in the silicate) to Na_2O (total alky. of the soln.) close to 1:1. Some NaOH (2–3 g./l.) should be added to the soln. Presence of Na_2CO_3 is undesirable, and addn. of soap increases the whiteness of the cloth, but decreases slightly its capillarity. More economical than use of peroxide alone is boiling in an alk. bath, bleaching with hypochlorite, finishing with Na_2O_2 with the addn. of acid. W. R. Henn

The bleaching of cellulose, with special reference to bast fibers. E. Butterworth. *J. Soc. Dyers Colourists* 55, 589–96(1939).—The problem is not the degradation of the cellulose but the bleaching of the color under conditions which will preclude attack on the cellulose when in the presence of the colored impurities. W. H. Boynton

Modern methods of bleaching rayon and cotton mixed fabrics. H. Joubert. *Bull. soc. ind. Rouen* 66, 348–66 (1938).—The effect of boiling with alkalies under pressure, and of Cl and H_2O_2 bleaching treatments upon cotton and rayon fabrics was followed by measuring the breaking strength, elongation, loss in weight, change in viscosity in cuprammonium soln., and the titration with $KMnO_4$ of the material extractable with boiling NaOH soln. Elaborate conclusions and recommendations are given for different cases. In general, J. prefers H_2O bleaching for rayon fabrics. Charles R. Phillips

The finishing of modern spun rayon fabrics. B. S. Hillman. *Rayon Textile Monthly* 20, 649–50(1939); cf. *C. A.* 33, 4030[9].—The scouring and dyeing of Cisalfa with various types of colors are outlined. *Ibid.* 708–9.—The dyeing of this fiber with developed dyes, with acid dyes and with chrome colors is discussed. The av. Cisalfa spun-rayon fabrics require little or no finishing materials to obtain a full desirable "woolly" feel and handle. Casein fabrics should be framed with a great deal of steam. W. H. Boynton

Technical evaluation of textile-finishing treatments. Lelia J. Winn and Edward R. Schwarz. *Rayon Textile Monthly* 20, 652–3, 710–12(1939).—See *C. A.* 34, 269[7]. W. H. Boynton

The emulsification of batching oils. Alexander King. *Textile Mfr.* 65, 439(1939).—Bentonite and inert Al hydroxide emulsions of great stability are produced. In solid stabilized emulsions, it is often possible to see under the microscope the solid particle μ adsorbed at the oil-water interface. In emulsions where there is a creaming tendency, homogenization will generally correct this. One lb. of kerosene emulsified in uniform particle diam. size of 1 μ has a surface area of 31,500 sq. ft. The vis-

cosity of an emulsion is essentially controlled by the percentage of the internal phase, the viscosity of the latter being of little importance. Emulsions of less than 40% internal phase are relatively mobile. Between 40% and 50% the viscosity increases rapidly, and over that becomes paste-like masses. An advantage of emulsification over the unemulsified oil technique for use with jute is that viscous oils of high lubricating value can be used.
Halsey E. Silliman

The rotproofing of textiles. S. G. Barker. *Proc. Food Group, Soc. Chem. Ind.* **1**, 102–8(1938); *Rev. Applied Mycol.* **18**, 527; cf. *C. A.* **33**, 1952[8].—Shirlan paste and powder gave excellent results in the preservation of fine fibers from attack by microörganisms and with coarser textiles a high lignin content confers strong resistance. A rotproofing material must not impair the intrinsic characteristics of each fiber and therefore each fiber is a sep. problem. The Thaysen acetylation process renders a cotton surface unsuitable as a nutrient. The iron-chromt proofer, chromium-clutch method (which gives good results if Cr content is maintained between 2 and 2.5%) and the use of creosote are also considered. O. E. S.

Recovering tin from waste phosphate liquors. C. C. Downie. *Silk and Rayon* **13**, 962(1939). Waste phosphate liquors are passed through a filter charged with active Al_2O_3. The ppt. is washed with Na_2S contg. free S forming SnS_2. The soln. of SnS_2 in excess Na_2S is acidified with HCl and the pptd. SnS_2 converted to SnO_2 by "steam-roasting."
Milton Harris

Fabricated stainless steel in the rayon and textile industries. H. B. Vollrath. *Rayon Textile Monthly* **20**, 713–15 (1939).—The corrosion resistance of so-called stainless steels is emphasized and the "Shotweld" process of welding is described. A unique rayon-spinning machine used in the Furness process of making cuprammonium yarn and employing stainless steel in its construction is described.
W. H. Boynton

Spot testing in textile analysis. Erwin J. Saxl. *Am. Dyestuff Reptr.* **28**, 757–8(1939).—Economy of time, minute amts. of material required, small lab. space and low initial and running expense of an outfit to carry on the tests feature spot tests. A spot paper test for Cu, using a 0.5% alc. soln. of rubeanic acid, is sensitive in a concn. of 1 250,000. A test for phenols consists of taking a drop of a soln. of the compd. in distd. water or alc. on a filter paper or spot plate, adding a 2% aq. soln. of phosphomolybdic acid and then a drop of concd. NH_4OH. A rich-blue color indicates the presence of phenolic compds.
W. H. Boynton

Methods of removing special stains in the power laundry. Polly Bell Kessinger, J. Fred Oesterling, Mae Yoder Moore and Pauline Beery Mack. *Starchroom Laundry J.* **46**, No. 8, 32, 35–6; No. 9, 92, 94–6; No. 11, 38, 40, 42 (1939).—Standard stain strips contg. 18 common stains were prepd. Data are given showing the reaction of these stains to 94 different laundry procedures done in the lab. A multiple suds and bleaching treatment removed all the stains, except nonwashable fountain-pen ink, India ink, dark-colored salve and iron rust. The first 3 of these can be removed by a boiling-out treatment with built soap and the iron rust can be removed by the addn. of an acid in one of the rinses. The standard stain strips were sent to 101 com. laundries and the results summarized. The recommendation is made that the bleach concn. should not be increased to obtain better stain removal, but that other parts of the washing formula be changed.
Charles R. Phillips

The background of filter powder; the nature and use of diatomaceous silica in the cleaning plant. F. L. Horine. *Natl. Cleaner Dyer* **30**, No. 10, 40, 78–9(1939).—A discussion of the use of diatomaceous silica as a filtering agent in purifying dry-cleaning solvent. C. R. Phillips

Dry clarification; its application to dry-cleaning solvents. H. E. Bierce. *Natl. Cleaner Dyer* **30**, No. 12, 38, 40, 59(1939).—The use of dry adsorbent powders or clays to remove dissolved impurities from dry-cleaning solvent is discussed. Charles R. Phillips

Filtering dry-cleaning solvent. Noel L. Cooperider. *Natl. Cleaner Dyer* **30**, No. 11, 32, 34, 63–5(1939).—Changes in filter design and problems met with in keeping the solvent free from impurities are described.
Charles R. Phillips

cis-Indigo (Heller) **10.** Chloromethyl compds. of sulfonamides [for treatment of textiles] (Brit. pat. 508,794) **13.** Treating liquid alkanes with SO_2 and Cl [for mercerizing assistants] (U. S. pats. 2,174,507–8–9) **13.**

Monoazo dyes. Frithjof Zwilgmeyer (to E. I. du Pont de Nemours & Co.). U. S. 2,175,370, Oct. 10. From components such as acetoacetyl-3-chloro-4-ethoxyaniline and the diazoimino compd. obtained from diazotized 2,5-diethoxyaniline and diethanolamine, etc., dyes are produced which dye cotton and regenerated cellulose bright fast yellow when used according to any processes for the application of ice colors. Several examples with details are given.

Producing azo dyes on the fiber. Karl Jellinek (to General Aniline Works). process of producing water-insol. azo dyes on the fiber according to the ice-color method involves developing the vegetable fiber impregnated with a coupling component adapted for the production of ice-colors in a soln. of a diazonium salt contg. a water-sol. chromic salt as alkali binding agent.

Chromable dyes of the triarylmethane series. Wilhelm Eckert and Karl Schilling (to General Aniline Works). U. S. 2,175,168, Oct. 10. Dyes dyeing animal fibers in an acid bath yellowish and bluish red and brown tints and of good fastness when after-chromed are produced by condensing hydroxytrimellitic acid or its anhydride with an equimol. proportion of an N-substituted *m*-aminophenol to form a benzoylbenzoic acid, and condensing the latter with a *m*-dihydroxy compd. having a reactive H atom of a sulfonic acid group in *p*-position to the hydroxy group. Several examples are given, and the dyes formed are suitable for chrome printing on cotton, rayon, etc., and may be chromed in substance and used for dyeing in an acid soln. Cf. *C. A.* **33**, 5199[4].

Vat dyes. Walter Kern (to Soc. pour l'ind. chim. à Bâle). U. S. 2,175,122, Oct. 3. Vat dyes, generally dyeing and printing cotton fast yellow or yellow-brown shades, are produced by treating fluoranthene, in the presence of a condensing agent such as $AlCl_3$ or $FeCl_3$ and at a temp. of 120–160°, with about 2.5 or more mol. proportions of phthalic anhydride, naphthalene-2,3-dicarboxylic acid anhydride, anthraquinone-dicarboxylic acid anhydride or their halogen- or alkyl-substitution derivs. Several examples with details are given.

Vat dyes in finely divided form. Wilfred M. Murch and Le Roy G. Kline (to Dow Chemical Co.). U. S. 2,176,011, Oct. 10. Ciba Blue 2BD or other vat dye is dissolved in concd. H_2SO_4 and the resulting soln. is brought into contact with water to ppt. the dye in finely divided form by atomizing the acid dye soln. and bringing the spray into contact with water.

Sodium salt of Lithol Red. Henry H. Reich (to Calco Chemical Co.). U. S. 2,174,501, Sept. 26. A Na salt of Lithol Red of strong bright color is produced by coupling a diazotized mixt. of Tobias acid and 2-chloro-5-aminotoluene-4-sulfonic acid on β-naphthol, the proportion of the chloroaminotoluenesulfonic acid being 5–10% the amt. of the Tobias acid.

Anthraquinone derivatives. I. G. Farbenindustrie A.-G. Brit. 508,503, June 30, 1939. These are made by subjecting the products obtained according to Brit. 487,877 (*C. A.* **33**, 402[6]) to the action of agents capable of transforming carboxylic acids into their chlorides, e. g., PCl_5, preferably in the presence of a high-boiling indifferent solvent, e. g., $PhNO_2$, 1,3,5-trichlorobenzene (I), and causing the chlorides obtained to react with an amine contg. at least 1 H attached to the N, preferably in the presence of a high-boiling indifferent solvent, e. g., *p*-chlorotoluene, I. The anthraquinone residue may contain further groups capable of reacting, which can be used for

further reactions. The products are *vat dyes* and may also be used as starting materials for other dyes.

Anthraquinone derivatives. I. G. Farbenindustrie A.-G. Brit. 508,708, July 5, 1939. 1,2-Pyridino- and 1,2-pyridono-anthraquinones and anthraquinoneacridines are made by causing aminoanthraquinone-*o*-aldehydes to react in H_2SO_4 or H_3PO_4 with ketones contg. a CH_2 group adjacent to the CO group, with free or esterified malonic or cyanoacetic acid or with resorcinol, phloroglucinol, α- or β-naphthol, 2,6- or 2,7-dihydroxynaphthalene, aminohydroxynaphthalenes, hydroxynaphthalene-carboxylic acids or -sulfonic acids, hydroxyanthracenes, hydroxyphenanthrenes, hydroxyazaphenanthrenes or hydroxythionaphthenes. Ketones specified are Me_2CO, MeEtCO, acetylacetone, acetophenone and its derivs. substituted in the aryl radical, methyl naphthyl ketones, desoxybenzoin, acetylanthracenes, acetylphenanthrenes, cyclohexanone, barbituric acid, 2,5-diketopiperazines, hydantoins, naphthindandiones and naphthalenediindandiones. The products may be *dyes* or *dye intermediates*. Among examples, (1) 1-aminoanthraquinone-2-aldehyde (I) is caused to react with β-naphthol in concd. H_2SO_4 to give anthraquinone-1(*N*),2,2′(*N*),1′-naphthacridine, which may be oxidized with CrO_3 to give a substance that dyes cotton red shades, (2) I is caused to react with *peri*-naphthindandione or naphthalene-1,8,4,5-diindandione, and (3) I is caused to react with barbituric acid to give anthraquinone-1(*N*),-2,2′(*N*),1′,3′,5′-diaza-4′,6′-dihydroxybenzacridine, which may be converted to a dichloro deriv. by reaction with PCl_5.

Hydroxymethylphenol derivatives. Reginald J. W. Reynolds, Eric E. Walker and Imperial Chemical Industries Ltd. Brit. 508,523, July 3, 1939. H_2O-sol. compds. are obtained by heating together a phenol substituted by 1 or more hydroxymethyl groups in the *o*- or *p*-positions and a salt of an inorg. acid anhydride addn. compd. of a hetero cyclic tertiary amine. The products may be used as *assistants in dyeing cellulose fibers*. The phenols used may also contain, as substituents in the nucleus or side chain, halogen atoms, acylamido, acylamidomethyl, alkyl, aralkyl or hydroxyaralkyl groups; the hydroxyaralkyl groups may be substituted by further hydroxymethyl groups.

***m*-Halo-*p*-ethoxyacetoacetanilides.** Frithjof Zwilgmeyer (to E. I. du Pont de Nemours & Co.). U. S. 2,175,371, Oct. 10. Products such as 3-chloro-4-ethoxyacetoacetanilide, m. 111°, and suitable for use as *intermediates in the production of azo dyes* are produced by treating a 3-halo-4-ethoxyaniline and an alkyl acyl acetate such as ethyl acetoacetate in a nonaq. medium such as xylene (suitably at a temp. of 148–150°).

4,5-Dichlorophthalonitrile. John S. H. Davies and William O. Jones (to Imperial Chemical Industries Ltd.). U. S. 2,174,568, Oct. 3. This compd. is produced by dehydrating 4,5-dichlorophthalamide with phosgene in a tertiary org. base such as dimethylaniline or the like and is a *dye intermediate*.

Dyeing materials such as mercerized yarn with vat dyes. Cornelis W. Zahn (to J. A. Carp's Garenfabrieken N. V.). U. S. 2,174,372, Sept. 26. Material to be dyed is immersed in an alk. soln. of the leuco base of a dye such as Indanthrene Brilliant Violet R. R. contg. a water-sol. org. substance such as MeOH acting as a solvent for the salts of the leuco base in a proportion of at least 20% of the dyeing bath, and the dye is formed on the fibers by oxidation. Numerous examples are given.

Printing textiles. I. G. Farbenindustrie A.-G. Brit. 508,554, June 30, 1939. Textile fabrics are printed with a compn. contg. a vat dye, a reducing agent, a thickening agent sol. or capable of swelling in H_2O, a H_2O-sol. salt of an acid H_3PO_4 ester contg. at least 1 aliphatic or cycloaliphatic hydrocarbon radical having at least 6 C atoms and, if desired, addnl. ingredients known in vat dye printing pastes. The compns. may also contain an aliphatic or cycloaliphatic alc. or ketone, which may be halogenated, e. g., the by-products obtained in the synthetic manuf. of MeOH, or cyclohexanol, BuOH, chloropropanol or chlorobutanol. Among examples, the Na salt of the reaction product of P_2O_5 and a mixt. of hexyl and heptyl alcs. is mixed with BuOH, H_2O and 2,1,2′,1′-naphthathioindigo and the product mixed with a printing thickening of wheat starch, tragacanth, British gum, glycerol, KOH, Na formaldehydesulfoxylate and H_2O; cotton and rayon fabrics may be printed with the resulting paste.

Printing textiles. Société Nobel française. Brit. 508,717, July 5, 1939. Fabrics are printed with prepns. contg. in admixt. (a) 1 or more phenol-CH_2O resins that are sol. in drying oils, (b) 1 or more drying oils, and (c) an org. solvent. A diluent, e. g., xylene, and a drier, e. g., a linoleate of Co, Mn, Pb or Ca, may be added. In an example, a resin is prepd. by mixing together xylenol, ester gum, $(CH_2O)_3$ and NaOH soln., boiling the mixt. for 15 min., adding HCl soln., boiling for 1 hr., washing with H_2O until neutral, adding more ester gum, cooking the mixt. for 2 hrs. at 210–220° and allowing to cool, and this resin is mixed with china-wood oil, the mixt. is heated to 270°, so maintained for 10 min. in a stream of CO_2 to prevent yellowing, allowed to cool and, when 90° is reached, ethyleneglycol monoethyl ether and its acetate are added. Dyes or pigments may be added and the prepns. may be used to produce resist effects with over-dyeing.

Textile printing pastes containing penetrating agents. Ivan F. Chambers and Arthur L. Fox (to E. I. du Pont de Nemours & Co.). U. S. 2,174,486, Sept. 26. Vat dye printing compns. are used which contain an alkali metal salt of allylthioglycolic acid, the Na salt of α,α-dimethylbenzylthioglycolic acid or various compds. of the general formula RXA where R is a hydrocarbon or benzothiazole radical joined to X through an acyclic C atom, X is —O— or —S—, and A is an org. or inorg. acidyl radical and when A is inorg. R must be aralkyl, and further characterized in that R or A may contain a substituent halogen, hydroxyl, alkoxy, aliphatic acyl or hydrocarbon radical. Numerous examples with details are given.

Apparatus for dyeing or bleaching textile materials such as skeins of yarn. Robert E. Oberholtzer (to James Lees & Sons, Inc.). U. S. 2,174,474, Sept. 26. Various structural and operative details.

Staple fiber yarns of materials such as cellulose acetate. Wm. I. Taylor (to Celanese Corp. of America). U. S. 2,174,607, Oct. 3. A process for the production of improved staple fiber yarns comprises twisting continuous filament yarns which have a basis of org. derivs. of cellulose, and which contain a high proportion of filaments of flat cross section setting the twist therein and untwisting such yarns, converting the yarns into staple fiber yarns by a direct conversion process, and thereafter subjecting the yarns to treatment with a bath of hot aq. liquid maintained at about its b. p.

Composite yarns. Vernal R. Hardy (to E. I. du Pont de Nemours & Co.). U. S. 2,174,878, Oct. 3. Composite yarns of wool-like character comprise a crimped thread of material such as a polyamide product and a spontaneously crimpable thread such as one also of polyamide material.

Pile yarn for carpets and rugs. Henry C. Forrest. U. S. 2,174,575, Oct. 3. Cuproammonium fibers are used, of an individual size of 25–30 deniers, sufficiently strong and pliable to be bent sharply without cracking.

Treating textiles. Heberlein & Co. A.-G. Brit. 508,665, July 4, 1939. Addn. to 494,663 (*C. A.* **33**, 2738[2]). A noncurling fabric stiffened and transparentized by treatment with a parchmentizing agent has at least 1 of its selvedges woven entirely or in part from pre-shrunk yarns. In an example, the selvedge yarn is boiled in Na_2CO_3 soln. and Turkey-red oil and allowed to shrink 10–12% by treatment while moist with 30°Bé. NaOH, the yarn is washed, acidified and dried.

Treating cotton textiles. Walter R. Cooke. Brit. 508,476, June 28, 1939. Cotton interlock fabric is subjected to an immersion in a hot aq. bath of a degreasing solvent for such a brief period as not to cause the surface of the fabric to rough up, the solvent being such as to remove sufficient of the contained oil, fat or wax to render the fabric absorbent to such a degree than when globules of H_2O are spilled on the surface thereof they do not stand

or run about thereon but are immediately absorbed. The fabric may be treated simultaneously with sufficient dye to cause it to retain its natural color. In an example, the fabric is passed through a hot aq. soln. of soap and "solvol" that may also contain Indian Yellow R or other monoazo dye so that the period of immersion is about 20 sec., cooled by a H_2O-spray, hydroextd., dried and calendered.

Improving the resistance of textile materials to creasing. Henry Dreyfus, Donald Finlayson and Richard G. Perry (to Celanese Corp. of America). U. S. 2,175,183, Oct. 10. Materials such as viscose or acetate rayon fabrics have incorporated in them an aldehyde such as CH_2O or an aldehyde-yielding substance and a Me, Et, Pr, Bu or Am ester of lauric, myristic, oleic, palmitic, stearic or ricinoleic acid and are heated (suitably to about 140°) to form a crease-resisting substance in the material.

Elastic fabric. Fernand F. Schwartz and Marc A. Chavannes (to American Ecla Corp.). U. S. 2,175,733, Oct. 10. A process for the manuf. of an elastic fabric consisting of textile materials such as wool and cotton and rubber involves weaving or knitting a fabric from textile threads some of which (such as those of wool) can be dissolved in a solvent such as hot dil. NaOH soln. without dissolving the others, applying rubber latex in a fine spray in insufficient amount to enclose the threads completely, and then treating the coated fabric with a solvent to dissolve the sol. threads and leave the insol. threads intact.

Parchmentizing cellulose material such as cotton fabrics. Joseph H. Shipp (to E. I. du Pont de Nemours & Co.). U. S. 2,174,534, Oct. 3. A material such as an unfinished cotton voile fabric is treated with a parchmentizing reagent comprising H_2SO_4 of at least 80% concn. together with 5–35% of a cellulose degradation inhibitor comprising a low mol. wt. amide, such as urea, of suitable soly. in the acid.

Apparatus for washing or other liquid treatments of multiple filament high denier rayon rovings. John P. Tarbox (to New Process Rayon, Inc.). U. S. 2,174,863, Oct. 3. Various structural, mech. and operative details.

Dry cleaning acid-soiled garments. Thomas M. Langan and Guy H. Condit (to Riverside Mfg. Co.). U. S. 2,174,793, Oct. 3. An arrangement of app. is described, and a process involving application to soiled garments, etc., of a nonaq. solvent and a soap, and reconditioning of the used soap soln. by adding an alkali to compensate for the acid soil extd. from the materials cleaned.

26—PAINTS, VARNISHES AND LACQUERS

A. H. SABIN AND CARLTON H. ROSE

War-time paints. E. Melling. *Paint Manuf.* **9**, 323 (1939).—Camouflage, black-out and road-line paints are discussed. W. H. Boynton

Methods of straining and clarifying paints. Milton M. Loeserman. *Am. Paint J.* **24**, 61-2(Nov. 27, 1939). W. H. Boynton

The influence of hot drying on the covering properties of paints. B. F. Tyurin. *Byull. Lako-Krasochnoĭ Prom.* **1938**, No. 5, 39–41; *Khim. Referat. Zhur.* **2**, No. 2, 120 (1939).—Paints prepd. from linseed oil with the usual drier and with different pigments (Pb-ZnO, lithopone, Pb-$PbCrO_4$ and ocher) were dried at 20, 40, 80, 100 and 120° for 2, 4, 6 and 8 hrs. The pigments have a considerable influence on the properties of the films. The Pb-$PbCrO_4$ paints are most elastic. In general the elasticity of the films changes differently with temp. and with duration of drying depending on the pigment. The water resistance increases with the increase of the temp. of drying (except for ocher). The temp. of drying optimum for water resistance is for $PbCrO_4$ between 60 and 80°, for ZnO about 80°, for ocher and lithopone about 100°. The optimum duration of heating is 2-4 hrs. Paints contg. lithopone and ocher should not be dried at high temp. W. R. Henn

White lead content of a good house paint. L. A. Thompson. *Am. Paint J.* **24**, 10, 12(Dec. 4, 1939).—Under normal conditions a most satisfactory pigment for house paint will contain 100% white lead. In areas with high humidity it should contain 50–75% white lead with the balance ZnO. In combination with ZnS pigments the white lead should be 25–50%. In combination with a co-fumed leaded zinc the white lead content should be 50–60%. In atms. contg. H_2S no white lead should be used in house paints. W. H. Boynton

Experiments with emulsion paints. S. P. Zel'din. *Byull. Lako-Krasochnoĭ Prom.* **1938**, No. 4, 35–6; *Khim. Referat. Zhur.* **2**, No. 1, 100-1(1939).—Paints prepd. with lithopone on a water-castor oil emulsion preserve their white shade much better than those prepd. with linseed oil. Green paints and carbon-black paints dry much faster when prepd. with a water-castor oil emulsion than with linseed oil. The emulsion black has a greater luster. Painting of the wooden platforms of trucks with the emulsion paints (on casein base as well as without it) gave satisfactory results. W. R. Henn

Exterior house-paint primers. E. Peterson. *Am. Paint J.* **24**, 64, 66(Nov. 27, 1939). W. H. Boynton

The painting of nonferrous metals. H. Eastwood. *Am. Paint J.* **24**, 47–8(Dec. 4, 1939). Essentials for good results are: (1) thorough cleaning, a chem. surface treatment and the proper selection of a primer. The most satisfactory types are alkyd enamels or aluminized synthetic spars, either alkyd or phenolic. W. H. Boynton

The development of paint systems for painting iron and steel. G. H. P. Lichthardt. *Am. Paint J.* **24**, 7-9(Dec. 4, 1939). W. H. Boynton

Pacific Coast fish oils in paint and varnish. Fred S. Dexter. *Am. Paint J.* **24**, 9–10(Dec. 4, 1939).—Pilchard, menhaden and sardine oils are widely used. W. H. B.

Nonpenetrating flatwall finishes. E. C. Alford. *Am. Paint J.* **24**, Convention Daily, 8(Nov. 3, 1939).—In the development of nonpenetrating flats the following vehicles were employed: (1) linseed-oil vehicles with CaO to produce soaps in the vehicle, (2) blown or polymerized oils, (3) sulfurized oils produced by dissolving S in oil during the kettling with or without the subsequent addn. of polymerized oils, (4) S_2Cl_2-treated oils (vulcanized oils), (5) castor-oil gels (blown castor oil) dissolved in oil or other vehicle, (6) a highly polymerized perilla oil completely lime-neutralized and thinned to a comparatively low nonvolatile content (about 38%). This is completely limeproof and when properly pigmented will carry large pigment vols. and produces a uniform flat, free from shiners, covers water stains and patches nicely with one coat, levels well and shows no sags or laps; its good penetration prevents peeling. W. H. Boynton

Increase of the drying properties of oils and fats. N. A. Suvorovskaya and Simova. *Byull. Lako-Krasochnoĭ Prom.* **1938**, No. 4, 42–5; *Khim. Referat. Zhur.* **2**, No. 2, 128(1939).—"Ryzhik" mushroom, tobacco, corn, sunflower and seal oils were oxidized with air at 150° and dehydrated at 280° in the presence of 3% of Zn and 1.5% of Al_2O_3. In all cases a hardening of the films was observed (as compared with the polymerized or with the only oxidized oils) as well as an increase of the I no. Extn. of the oxidized and dehydrated oils with acetone yielded a fraction similar to linseed oil. The possibility of completely replacing linseed oil with the semidrying oils has not been proved, but in some cases the semidrying oils can be used with success. W. R. Henn

Fish oils in the production of drying oils. Kulikov. *Byull. Lako-Krasochnoĭ Prom.* **1938**, No. 6–7, 64–72; *Khim. Referat. Zhur.* **2**, No. 2, 118(1939).—Thick pastes were prepd. from lithopone, Fe_2O_3, ocher, carbon black and ZnO with drying oils consisting of mixts. of prepd. seal oil (oxidized or polymerized either in the presence or in the absence of catalysts) with linseed oil or with poly-

merized castor oil and semidrying oils. The pigments were dild. with drying oil (mostly with natural oils) until a paint consistency was obtained and the drying properties of the paints and the hardness of the films obtained were detd. Part of the paints were tested for elasticity, spreading properties, ability to dissolve and resistance to water and weather. The combination drying oils dry slowly and sticky for over 10 days. The 3-component oils are superior to the 2-component oils in hardness. The viscosity of the oxidized oil must not be below 4 min. 30 sec. on the NILK funnel at 20°. Paints prepd. with synthetic oils without the addn. of natural oils are sticky and do not harden well. Four months' exposure on sheet iron showed satisfactory results. The thick paste prepd. from ZnO did not thicken for 1 month. Paints prepd. from ocher, from ZnO and from Fe_2O_3 were water-resistant, but those prepd. with lithopone and with carbon black were not water-resistant. W. R. Henn

Review of domestic tung-oil industry. W. E. MacKee. *Am. Paint J.* 24, 21–2, 24 (Nov. 27, 1939). W. H. B.

Acid number, viscosity and livering characteristics of boiled linseed oil. Lawrence Gussman. *Am. Paint J.* 24, Convention Daily 16, 18, 20 (Nov. 1, 1939).—The acid no. *vs.* logarithm viscosity plot for any one kettle bodying condition is a straight line, the slopes differing with temp. and the acid no. and viscosity of a blend of 2 oils on any one line falls on that line. Cross blending of oils bodied at 2 different temps. yields acid nos. and viscosity characteristics of oils bodied at intermediate temps. The study was confined to acid no., viscosity and temps. Conclusions: (1) A new livering line which has practical significance to both the ink and paint industry is defined through the use of specially prepd. oils to give points that lie in the crit. livering region. This shows (*a*) any oil, the viscosity and acid no. of which will be above this line, will liver and (*b*) below this line, there will be no livering. (2) The equation for the livering line is $A = 145 - 0.086\ u$ where A = acid no. and u = viscosity. (3) Viscosity varies semilogarithmically when 2 different oils that have been bodied at the same temp. are blended. (4) Blends of oils of different viscosities bodied at the same temp. fall on the acid no. *vs.* viscosity plot of the bodying curve. (5) Blends of oils of different viscosities bodied at different temps. yield oils that have similar acid no. and viscosity characteristics to those of oils bodied at an intermediate temp. W. H. Boynton

The production of polymerized castor oil. S. I. Karasik and G. M. Sokolova. *Byull. Lako-Krasochnoĭ Prom.* 1938, No. 4, 32–5; *Khim. Referat. Zhur.* 2, No. 1, 115 (1939).—A method of polymerization has been developed in the "Krasnyĭ Malyar" plant in which the temp. of the oil is raised to 280° during approximately 12 hrs., after which the temp. is kept const. for about the same length of time. The η of the oil during the first 18–20 hrs. (4–6 min. in the NIIKL funnel) rises slowly and then sharply. By working with refined castor oil the time of polymerization can be reduced. W. R. Henn

Water-castor oil emulsions for water-oil colors. S. P. Zel'din, N. G. Kiselev and Samarin. *Byull. Lako-Krasochnoĭ Prom.* 1938, No. 4, 36–41; *Khim. Referat. Zhur.* 2, No. 1, 100 (1939).—Ethanolamine and triethanolamine in the free state as well as in the form of oleic soaps are excellent emulsifiers for the system castor oil-water (1:1). At small concns. of emulsifier (0.25–6% of the ethanolamine soap or 0.1% of ethanolamine) water-oil emulsions are obtained, while at large concns. of the emulsifier (10% and 1%, resp.) oil-water emulsions are obtained. At medium concns. the emulsions are not clearly defined. Emulsions of the type water-oil have a dense viscous consistency, and their stability decreases with the increase of the concn. of the emulsifier. The oil-water emulsions are thin and their stability increases with the increase of the concn. of the emulsifier. W. R. Henn

Scientific methods of varnish manufacture. VIII. Oils used in varnishes and synthetic resins. Ralph H. Huff. *Am. Paint J.* 23, 56, 58, 60, 62–3 (Sept. 18, 1939); *Ibid.* 50, 52, 54, 56, 58 (Oct. 2, 1939); cf. *C. A.* 33, 9016⁴.—A historical review of varnish oil history. The chemistry of vegetable oils and other oils used in varnishes is briefly considered. *Ibid.* 24, 65–8, 70 (Oct. 16, 1939).—A consideration of the glycerol mol. and the types of compds. formed when chem. combination takes place between glycerol and a fatty acid, methods of treatment of varnish and paint oils after expression of the oils are included. *Ibid.* 54, 56–7, 58, 60, 62 (Oct. 30, 1939).—The Twitchell process of fat-splitting and oil-refining methods are outlined. *Ibid.* 48, 50, 52, 54, 56 (Nov. 13, 1939).—The prepn. of varnish makers' linseed oil (alkali-refined oil), acid-refined linseed oil, oil of low acid value, oil of high acid value are included. *Ibid.* 54, 56, 58, 60 (Nov. 27, 1939).—Bleached raw oil, the air blowing of oils (oxidized oils) and boiled oils are considered. *Ibid.* 54, 56, 58, 60 (Dec. 11, 1939).—Boiled oils including fire boiled linseed oil, bleached or extra-pale boiled oil, "bung hole" boiled oils (produced by adding liquid driers to ordinary raw linseed oil in quantity intended to be sufficient to make the oil dry at a rate similar to that of genuine boiled oils and "boiled paint oils" are included. Eighteen references. W. H. Boynton

Investigation of copals found in the U. S. S. R. deposits, and their adaptation for varnishes. V. P. Tsybasov. *Byull. Lako-Krasochnoĭ Prom.* 1938, No. 11–12, 59–61; *Khim. Referat. Zhur.* 2, No. 1, 99 (1939).—Geological expeditions in 1937 discovered deposits of copals in the Caucasus and in the Far Eastern region. The Caucasus copals m. 210–30°, and the Far Eastern copals m. 250–80°. The copals, when fused at 280–320° (like the foreign copals), acquire the ability to combine with oil. Oil-tar varnishes, when prepd. from these copals, were satisfactory as to transparency, drying qualities, diffusion, absence of dirt, warming qualities, hardness, elasticity and waterproofness. The varnishes were too dark in color, especially those prepd. from the Far Eastern copals. The results of the lab. expts. were substantiated by plant expts. W. R. Henn

Nitrocellulose lacquers for special purposes. A. Kraus. *Nitrocellulose* 10, 203–5 (1939); cf. *C. A.* 33, 9019⁴.—A review. E. M. Symmes

The addition of driers to lacquers prepared with synthetic copals. A. Gamazov. *Byull. Lako-Krasochnoĭ Prom.* 1938, No. 5, 28–32; *Khim. Referat. Zhur.* 2, No. 2, 120 (1939).—Expts. with lacquers prepd. from synthetic copals (44 and 50 B) and with albertols 209 α and 111 α showed that all lacquers prepd. with resinous driers give no ppt. while those prepd. with the linoleate driers form a ppt. Lacquers prepd. from linseed oil with resinate driers dry up "from dust" faster than the lacquers with linoleate driers. The films of the lacquers with linoleate driers are harder than those prepd. with resinate driers. Addn. of resinate driers lowers to a certain extent the water resistance of the lacquers. Lacquers from synthetic copals should be prepd. with resinate driers. W. R. Henn

Combining Pechory asphalt with linseed oil. S. A. Uranov and E. N. Orlova. *Byull. Lako-Krasochnoĭ Prom.* 1938, No. 4, 21–6; *Khim. Referat. Zhur.* 2, No. 1, 102 (1939).—The enriched Pechory asphaltite (asphaltenes 54.24%, carbenes, 2.26%, carboids 0.98% and ash 0.20%) was fused with oil in the ratios of asphaltite to oil 1:1, 1:2 and 2:1. By dilg. the lacquers with 200–500 cc. of lacquer kerosene a part of the highly carbonized components (25–36% of the wt. of asphaltite) was pptd. A min. pptn. was obtained with the ratio asphalt:oil = 1:2. The amt. of the assimilated highly carbonized components decreased with diln. This dependence is observed least with asphalt:oil = 1:2. Lacquer kerosene is not suitable for the detn. of the combining ability of the asphalts. Turpentine is suitable. It is proposed to call the "true combining ability" of asphalt with oil expressed in percentage the ratio of the assimilated (not sepd. with turpentine), highly carbonized components to the total asphalt content. W. R. Henn

Investigation of the Sadkin asphaltite. S. A. Uranov and N. B. Riskina. *Byull. Lako-Krasochnoĭ Prom.* 1938, No. 5, 24–8; *Khim. Referat. Zhur.* 2, No. 2, 120 (1939).—Samples taken from a depth of from 17 to 35 m. showed that the Sadkin asphaltite is nearly pure bitumen contg.

only 0.8% of ash. The content of the asphaltogenic acids varies from 0.77 to 2.3%. The combining power of asphaltite with linseed oil is smallest at the ratio of 1:2. At 2 1 asphaltite combines with the oil practically completely. W. R. Henn

Egg tempera prepared from dry yolk. K. A. Gorbatov and M. L. Solovova. *Byull. Lako-Krasochnoĭ Prom.* **1938**, No. 4, 51-8; *Khim. Referat. Zhur.* **2**, No. 1, 101 (1939).—Expts. on the prepn. of emulsions from water, linseed oil and dry yolk (4-5% of moisture) showed that the emulsifying ability of dry egg yolk is considerably higher than that of the normal egg yolk. Viscosity of the emulsion of dry egg yolk is greater than that of the emulsion of normal egg yolk. When 1-4% of AcOH is introduced into the emulsion as peptizer the emulsions can be easily mixed with pigments (sienna, etc.) producing plastic pastes. The liquid capacity of these pastes is much lower than that of those prepd. without the addn. of AcOH in spite of the high viscosity of the emulsion. An increase of the concn. of the acid increases the viscosity of the initial emulsions, and it also increases the velocity of the transformation of the paint into the irreversible state. An antiseptic in the paste is necessary to prevent molding. Pastes prepd. with AcOH are entirely satisfactory for artists' paints. W. R. Henn

Prepn. of bright pyrolyzed resins from pyrolyzed petroleum products (Bespolov) **22**.

Water-insoluble metal soaps suitable for use in paints, printing inks, etc. Frederick A. Stresen-Reuter and Charles Rimpila (to Frederick A. Stresen-Reuter, Inc.) U. S. 2,175,489, Oct. 10. A product suitable for use in paints, varnishes, printing inks, etc., comprises a water-insol. Cu soap derived from a pine-wood product such as "Spefa" contg. a major proportion of unsatd. acids, a minor proportion of rosin acids and a small proportion of unsaponifiable material calcd. as a sterol. U. S. 2,175,490 relates to alk. earth metal soaps of similar material; and U. S. 2,175,191 relates to Pb, Co, Mn and other soaps of such material.

Azo pigments. Vincent C. Vesce (to Harmon Color Works, Inc.). U. S. 2,174,954, Oct. 3. In producing azo pigments from aq. suspensions of solid insol. phenolic coupling components by coupling with a diazo soln., the solid component is subjected to wet milling to produce a suspension of fine particles with worked and amorphized surfaces and is then coupled with a diazotized amine in aq. soln.

Phthalocyanine pigments. Interchemical Corp. Brit. 508,583, July 4, 1939. See U. S. 2,138,384 (*C. A.* **33**, 1973[7]).

Pigment containing titanium oxide. Max H. Kliefoth (to Sherwin-Williams Co.). U. S. 2,174,920, Oct. 3. A pigment which has good hiding power comprises a mech. blend of 10-60% pigment TiO_2 and an alk. earth metal sulfate such as $BaSO_4$, the pigment TiO_2 consisting of a cryst. TiO_2 produced by the calcining of a hydrate formed by the pptn. of a Ti tetrafluoride compd. in aq. soln. by use of NH_3, fritting materials being substantially absent in the reaction mass after pptn. of the hydrate is effected and the alk. earth metal sulfate being produced by pptn. in aq. soln., the sizes of substantially all the individual particles of both the pigment TiO_2 and alk. earth metal sulfate being less than 0.5 micron.

Zinc sulfide pigment. Albert T. Mertes (to E. I. du Pont de Nemours & Co.). U. S. 2,175,273, Oct. 10. An oxidic Zn material such as crude Zn oxide is treated with an ammoniacal soln. of NH_4 sulfite, undissolved residue is sepd. after the soln. has reached the desired concn., impurities are removed from the Zn liquor, as by use of metastannic acid, and the purified liquor is treated with a sol. sulfide to form ZnS.

Synthetic resin coating compositions. Charles Bogin (to Commercial Solvents Corp.). U. S. 2,174,495, Sept. 26. A coating compn. possessing decreased gelling tendencies comprises a tough and strong artificial resin resulting from the conjoint polymerization of a vinyl halide with a vinyl ester of a lower aliphatic acid, the resin being dissolved in a sufficient quantity of a volatile solvent having a low rate of evapn. to decrease the gelling tendency of the resulting compn. comprising an alkyl diacetone ether, to make a readily flowable compn. adapted to produce resistant, adhesive and stable protective or ornamental surface coatings.

Synthetic resin coating compositions. Wm. H. Butler (to Bakelite Corp.). U. S. 2,174,819, Oct. 3. A method of improving the properties of resinous condensation products of phenols and CH_2O for the production of oil resin coating compns. comprises heating the condensation product in the absence of added substances other than inert gaseous substances such as steam at a temp. of above 175° whereby the soly. of the condensation production in vegetable oils is substantially improved

27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

Examination of fatty material taken from an Egyptian tomb at Armant. T. P. Hilditch. *Analyst* **64**, 867-70 (1939). The specimen was found to contain 35% of neutral fatty matter of mainly satd. character, about 25% of free satd. fatty acids and about 40% of material insol. in light petroleum. The substance probably contained originally at least 80% of fat. The other material consisted probably of triolein which, as a result of prolonged atm. action, broke down into nonanoic (pelargonic) and azelaic acids or even simpler products of water-sol. character. W. T. H.

The properties and recovery of wool fat. Hans J. Henk. *Seifensieder-Ztg.* **66**, 820-1(1939). A. Guillaudeu

Fatty acids and glycerides of the body fat of she-goats. D. R. Dhingra and M. Haneef. *J. Soc. Chem. Ind.* **58**, 292-3(1939).—The tallow was obtained from the back tissues of Punjab she-goats. The characteristics of the tallow were: (fat) sapon. no. 287.5, I no. (Wijs) 32.8, acid no. 4.8, unsaponifiable matter 1.5%, setting point 45.8°, n^{40}_{D} 1.4600; (fatty acids) sapon. no. 275.7, I no. 34.2, titer 46.7°, solid fatty acids 58.2% and isooleic acids 7.8%. The component fatty acids, as detd. by ester fractionation, were: lauric 2.5, myristic 2.8, palmitic 27.5, stearic 26.0, arachidic 2.2, oleic 34.8 and linoleic 2.3%. The unsaponifiable matter present was 1.9%. The fat was oxidized with $KMnO_4$ and the fully satd. glycerides (30.3%) were sapond. The acids obtained were methylated and the resulting esters were fractionated to det. the acids of the component glycerides. These acids comprise: myristic 2.4, palmitic 41.7, stearic 51.8 and arachidic 4.1%. From the above data, and from data obtained from fractional crystn. of the fully satd. glycerides, the approx. compn. of the latter is probably: tristearin 2, distearoarachidin 3, palmitodistearin 3-4, tripalmitin and dipalmitostearin 5% each; the remaining 11-12% comprise the glycerides of myristic, palmitic and stearic acids. The nonfully satd. glycerides consisted of 6-8% triolein and about 7% of simple trisatd. glycerides. The similarity of this fat to he-goat tallow (cf. Dhingra and Sharma, *C. A.* **33**, 1527[6]), mutton tallow and beef tallows is discussed. 9 references. L. W. G.

Some notes on the determination of moisture and volatile matter in fats and oils. N. T. Joyner and S. J. Rini. *Oil & Soap* **16**, 233-6(1939).—The method of moisture detn. introduced by Parsons and Holmberg (*C. A.* **31**, 7547[6]), in which H_2O is evolved from the sample and absorbed on $CaCl_2$, is abs. and is applicable to all types of oils and fats, except those contg. residual solvent. Of the methods recommended by the A. O. C. S. for the detn. of H_2O and volatile in oils and fats, the vacuum oven was

found the most accurate except on high-fat acid coconut oil. The hot-plate method gave the highest moisture results when the test was conducted according to the procedure given in the A. O. C. S. methods. When first traces of smoking were observed under a strong beam of concd. light, resulting moistures approached those of the vacuum oven. Moisture results obtained by the air oven, if corrected for peroxide absorption, approach those of the vacuum oven. The percentage of residual solvent in extd. soybean oil, independent of moisture, can be detd. by adsorption of solvent vapor on activated charcoal. E. S.

Fat acids and glycerides of neem (margosa) oil. T. P. Hilditch and K. S. Murti. *J. Soc. Chem. Ind.* **58**, 310–12(1939).—A sample of Cawnpore neem oil had the following compn.: palmitic 14.9, stearic 14.4, arachidic 1.3, oleic 61.9 and linoleic acid 7.5%. It contained about 0.6% fully satd. glycerides and 22% of tri-unsatd. glycerides, the other components being stearodi-olein (34%), palmitodi-olein (26%) with oleo-palmitostearin (12%) and oleo-dipalmitin (5%). The presence of characteristic nonfatty compds. which confer on neem oil certain *medicinal properties* and an unpleasant odor led to difficulties in one stage of the analysis. The component glycerides follow the usual rules of glyceride structure in seed fats. If the tri-unsatd. glycerides should consist of linodiolems, neem oil is a marked instance of the application of the "rule of even distribution." E. Scherubel

Rancidity prevention. Paul I. Smith. *Soap* **15**, No. 12, 21-3(1939).—Antioxidants used in the soap industry are discussed. Recently some of the lesser known antioxidants used in the rubber industry have come in for attention as fat antioxidants, especially the phenylnaphthylamines. The condensation products of acetone with aminodiphenyl, and the nonstaining rubber antioxidants such as the condensation products of dimethylphenol and formaldehyde and a secondary amine and the condensation products of styrene with phenols have interesting potentialities. Recently also attention has been given to the claims of the esters of glycerol with phosphoric and higher fatty acids. E. Scherubel

A rapid method for the determination of iodine number. H. D. Hoffman and C. E. Green. *Oil & Soap* **16**, 236–8 (1939).—Expts. were conducted with the method of Scott in which mercuric acetate is used as an accelerator in conjunction with a soln. of I in pure benzene. It is suggested that accurate I nos. can be rapidly detd. by modifying the standard method, adding 10 cc. of a 2.5% soln. of mercuric acetate dissolved in glacial AcOH to the sample directly after adding the Wijs soln. Allow 3 min. absorption time and proceed with the detn. as in the standard method. E. Scherubel

Relation between the iodine number and refractive index of crude soybean oil. K. R. Majors and R. T. Milner *Oil & Soap* **16**, 228–31(1939).—The I no. of soybean oil can be detd. by calcn. from the measurement of n with an accuracy comparable to any chem. method, provided that the instrument used is sufficiently accurate, the measurements are carefully made, and, for any given crop year, a correlation curve is established. Of 400 samples of soybeans, embracing 185 varieties, so far examd. only 3 have given oil whose I no. and n did not conform satisfactorily. E. Scherubel

Preparation of castor oil. D. Yu. Gamburg. *Byull. Lako-Krasochnoĭ Prom.* **1938**, No. 5, 32-3; *Khim. Referat. Zhur.* **2**, No. 2, 121(1939).—Heating castor oil without blowing for 24 hrs. had almost no effect. Heating the oil for 16–20 hrs. at 250° in a current of air at a velocity of 6 l./min. caused the oil to darken. The oil becomes sticky and dissolves in basic solns. with difficulty. Heating in the presence of such catalysts as rosin, captax, flowers of S and $AlCl_3$ as well as *in vacuo* caused little change in the qualities of castor oil. W. R Henn

Molecular distillation of soybean and corn oils. Herbert W. Rawlings. *Oil & Soap* **16**, 231-2(1939).—A batch of 1000 gals. of soybean and a batch of 700 gals. of corn oil were molecularly distd. at an av. abs. pressure of 0.002 mm. of Hg and at a rate of 7 to 8 gals. per hr. Four and 5 fractions were, resp., obtained and analyzed. The results are tabulated. Although no great fractionation of the glyceride constituents occurred, the unsaponifiable portion of the oil was almost completely present in the first 2 fractions. It is possible by mol. distn. to remove the unsaponifiable from these oils without resorting to sapon. and extn. The coloring matter and odorous constituents volatilize readily and sep. almost entirely from the oil, so that the later fractions consist of fairly pure glycerides and are as bland as bleached and steam-deodorized oils. E. S.

Density and viscosity of glycerol solutions at low temperatures. Edmund Green and John P. Parke. *J. Soc. Chem. Ind.* **58**, 319–20(1939).—The densities and viscosities of aq. glycerol solns. contg. 30 to 80% of glycerol were detd. at temps. between −5° and −40°. The viscosities obtained were found to be higher than published figures which were derived from data at temps. above 0°, by extrapolation along straight lines plotted on logarithmic viscosity temp. scales. Tables and curves are given. E. Scherubel

A distillation method for water in soaps. Ralf B. Trusler. *Oil & Soap* **16**, 239-41(1939).—It is proposed to modify the present distn. method for moisture in soaps by converting the water-sol. soaps into insol. soaps by adding 10 g. anhyd. powd. $BaCl_2$ to a 10-g. sample of soap in 250 ml. of toluene in a 500-ml. distn. flask. The use of $BaCl_2$ as an antifoaming agent is superior to Na acetate in respect to speed, ease of handling and also in leaving more easily cleaned app. It offers another advantage in that anhyd. $BaCl_2$ is more easily prepd. than anhyd. Na acetate. E. Scherubel

Liquid shampoos. C. A. Tyler *Soap* **15**, No. 11, 21-3, 69(1939).—This is a discussion of raw materials and formulas. E. Scherubel

Industrial soaps. John Glenn. *Soap* **15**, No. 11, 27-30, 69-70(1939).—The compn., uses and development trends of non-household soap products in the English market are discussed. E. Scherubel

Soap manufacture under war conditions in England. Paul I. Smith. *Soap* **15**, No. 11, 31, 41(1939). E. S.

Abrasives. Richard J. Roley. *Soap* **15**, No. 12, 24-6, 70(1939).—The occurrence and characteristics and use of abrasives in soaps and scouring powders are discussed. E. Scherubel

South African fish products—liver oils (Molteno, Rapson) **17**. Occurrence of free vitamin A alc. in fish livers (Mead) **17**. Preserving oxidizable substances [unsatd. fatty oils, soaps] (Brit. pat. 508,442) **13**.

28—SUGAR, STARCH AND GUMS

J. K.

Thermophils in sugar. T. G. Gillespy. *Univ. Bristol, Fruit Vegetable Preservation Research Sta., Campden, Ann. Rept.* **1938**, 45–59.—Many samples of sugar refined in Britain were examd. for thermophilic spoilage bacteria and a considerable portion was found to be unsuitable for canning purposes. Canning expts. with processed peas showed that when unsuitable sugars were used sterility was not attained by normal processing. Data are given on the content of spores of thermophilic bacteria in the products obtained in the various stages of the manuf. of raw beet sugar and in the refining of raw beet and cane sugars. Eighteen references. K. D. Jacob

Physicochemical phenomena of sulfurization of sugar-beet juices. O. Spengler. *Centr. Zuckerind.* **47**, 782–4 (1939).—Sulfurization of juices poisons the catalyst of discoloration, viz., iron, and is thought to keep many colored materials in a colorless leuco state. The change in pH caused by H_2SO_3 may aid the coagulation of colloidal par-

ticles. The viscosity of the juices is reduced by the conversion of dissolved $CaCO_3$ to $CaSO_3$ during sulfurization. W. W. Binkley

Lime salts in beet-sugar juices. J. Dědek. *Facts About Sugar* **34**, No. 11, 42–4; No. 12, 38–9, 41(1939).—A summary of articles previously published by D. and collaborators, stressing application of the results to sugar-factory control. F. W. Zerban

Detection of sugar in feed water with the aid of conductivity measurements. E. Troje-Brieg. *Centr. Zuckerind.* **47**, 758–9(1939).—The cond. of untreated feed waters of an av. cane-sugar refinery varies between 2500 and 4700 ohms. The av. fluctuation is between 2800 and 3800 ohms. An increase of 0.1% of sugar causes an increase of 1500–2000 ohms. Traces of sugar are more easily detected in refinery waters with lower conds. Refinery waters treated with Na_3PO_4 behave normally. The presence of α-naphthol facilitates the detection of sugar by conduction; the derivs of α-naphthol are even more effective. W. W. Binkley

Use of the collactivit method in the sugar-refining operation and its results. K. Lanksch. *Centr. Zuckerind.* **47**, 818–21(1939).—Collactivit decolorized and clarified dark sirups better than diatomaceous earths and boneblack. The collactivit is prepd. by the action of concd. H_2SO_4 on sawdust. The sawdust must be dry and made from coniferous trees. The reaction proceeds rapidly at 110°. After completion, the products are washed thoroughly, and the pH of an aq. suspension of collactivit (500 g./l.) is adjusted to 8.4 with lime to inhibit the formation of invert sugar. The concn. of invert sugar is 0.7% at pH = 7.4; 0.3 to 0.4% at pH = 8.4. W. W. Binkley

Borsig mammoth beet pump in the sugar industry. Friedrick Pickert. *Centr. Zuckerind* **47**, 706–8(1939). W. W. Binkley

Sirup from sweet-potato starch. A pilot-plant investigation. Lawrence E. Stout and Carl G. Ryberg, Jr. *Ind. Eng. Chem.* **31**, 1451–4(1939).—A sweet sirup was prepd. from sweet-potato starch and the method of prepn. including app. used given in detail. The effects of pressure and acid concn. on the rate of hydrolysis were studied and compared with those of cornstarch. The iso elec. point of the undesirable humus, and the amt. of activated C and length of time necessary to decolorize the sirup were detd., and the clarity, color, flavor and aftertaste of the resulting sirup observed. The conditions required for the production of sweet-potato sirup do not differ greatly from those of cornstarch. 19 references. J. C. Jurrjens

Manufacture of pulp from bagasse (Tanaka, Koriyama) **23**. Lysimeter study of losses of applied potash by leaching from an acid soil [effect on sugar cane] (Gow) **15**. Inulin and its mol. wt. (Bezzi) **2** Report on chemistry [fertilizer requirements of sugar-cane soils] (Craig) **15**.

Refining cane sugar. Geo. E. Stevens (to Western States Machine Co.) U. S. 2,175,998, Oct. 10. An arrangement of app. is described, and a process which involves removing relatively impure adherent substantially dry sirup from grain sugar by mixing the sugar with an affination sirup having a dry substance not substantially below 80 in proportions such as to produce a thick, viscid mass unadapted for introduction into and purging in centrifugal machines, stirring the mass and adding dry heat thereto to raise its temp. to above 70° at which a magma of a fluidity sufficient to loosen the adherent dry sirup on the sugar grains and to be centrifuged effectively has formed, and then centrifuging the hot magma.

White sugar refining. Eugene Roberts (to Western States Machine Co.). U. S. 2,175,996, Oct. 10. An arrangement of app. is described, and a process for white sugar refining which comprises boiling sirup in a vacuum pan at a temp. between 80° and 90° to produce white massecuite of greater than 91% dry substance, dropping the massecuite into a mixer and there maintaining its temp. and fluidity uniform and substantially the same as in the vacuum pan, introducing successive charges of the hot massecuite into a centrifugal during acceleration corresponding to the acceleration of a 40″ centrifugal between about 300 and 700 r. p. m., sepg. more than 90% of the mother liquor in less than one min. by revolving the centrifugal to produce forces corresponding to those produced by accelerating a 40″ centrifugal to a speed in excess of 1250 r. p. m. within 40 sec. from the introduction of the hot charge, thereafter further cleaning the remaining sugar and maintaining it at a high temp. by spraying with a washing medium in liquid form at a temp. above 80° while the centrifugal is revolving at high speed, and discharging from the centrifugal substantially pure sugar at a temp. in excess of 70° and having a moisture content of less than 1.2%.

Centrifugal separation of sugar crystals from liquids. Eugene Roberts (to Western States Machine Co.). U. S. 2,175,995, Oct. 10. Improved sepn. is effected by accelerating the speed of a centrifugal used to over 1250 r. p. m. within less than 40 sec. after a charge is introduced.

Moisture trap for use with evaporators and vacuum pans of sugar factories, etc. Roy L. Lay. U. S. 2,174,794, Oct. 3. Various structural details.

Dextrose production from corn starch or other materials. Roscoe C. Wagner and Paul L. Stern (to Clinton Co.) U. S. 2,175,369, Oct. 10. An arrangement of app. is described, and a method for the production of a cryst. hydrate dextrose from an impure dextrose-contg. soln. which involves seeding in a water-jacketed crystg. tank a body of the soln. having a d. of 40°Bé. and a temp. of about 50°, the seed employed being a magma left in the crystallizer from a preceding batch and in the amt. of about 3 to 5% of the capacity of the crystallizer and maintaining the soln. temp. above 43° for about the first 3 days while circulating warm water at about 43° through the jacket slowly to withdraw the residual heat and exothermic heat of crystn. as the crystals develop until the supersatn. of the soln. is diminished enough to permit lowering of the temp. below 43° without promoting any substantial addnl. growth of new crystal nuclei.

Starch modification and conversion products. Philip A. Singer. U. S. 2,175,486, Oct. 10. A process for the prepn. of products for use as adhesives, sizings or in the prepn. of foods and beverages, etc., involves heating to about 60–70° a mixt. of starch and water contg. about 25–50% dry starch solids, then adding the min. quantity of diastase necessary to make the soln. mobile after further heating, gradually increasing the temp. over a period of about 10 min. to about 80° when the mixt. becomes very thin, rapidly raising the temp. to the b. p. of the mixt., heating to gelatinize thoroughly the starch, cooling to about 80°, adding a cold water infusion of malt having a diastatic strength of 75° Lintner, maintaining at the specified temp. for about 25–30 min. and then rapidly raising the temp. to the b. p. to arrest further reaction. Several examples with similar details of procedure are given and numerous uses of the product are mentioned.

29—LEATHER AND GLUE

HENRY B. MERRILL

Notes upon the analyses of leathers. II. Liboslav Masner. *Tech. Hlídka Koželužská* **15**, 59–61(1939); cf. *C. A.* **33**, 6639⁸. In 5 tables the chem. and phys. properties of sole leather, box calf, cow box, dull box prepd. in Czechoslovakia are given. The tables are to serve as standards. Frank Maresh

New methods for the two-bath chrome-tanning method. E. Bělavský. *Tech. Hlídka Koželužská* **15**, 62–3, 67–8, 75 7(1939)(German summary); cf. *C. A.* **34**, 2843.—B. shows the incorrectness of present chem. reactions which indicate the course of events occurring in chrome tanning. From stoichiometric computations it is evident that present reactions do not consider (*a*) the losses of chrome in the 1st bath, (*b*) the loss of thiosulfate in the 2nd bath and (*c*) the correct valence and basicity of the Cr salts deposited upon fibers. B. presents 20 sequential corrected stoichiometric equations. In a comparison of the Czechoslovakian and American 2-bath tanning processes B. finds the Czechoslovakian process the more economical in chemicals, giving a lower elasticity, a firm surface, and a correct S content, and yielding better hygienic conditions (removal of SO_2, protection against Cr ulcers). F. M.

Retarding deterioration of hides (U. S. pat. 2,176,025) **12.** Treating liquid alkanes with SO_2 and Cl [to produce tanning agents] (U. S. pats. 2,174,507–8–9) **13.** Chloromethyl compds. of sulfonamides [for treatment of leather] (Brit. pat. 508,794) **13.**

Tanning agents. Friedrich-Wilhelm Guthke (to I. G. Farbenind. A.-G.). U. S. 2,174,287, Sept. 26. A condensation product obtainable by causing a dihydroxydiphenylsulfone to react with a water-sol. salt of sulfurous acid and a formaldehyde substance is combined with a substance obtainable by the reaction of a condensation product of a phenol such as β,β-di-(4-hydroxyphenyl)-propane and a ketone with a salt of sulfurous acid and a formaldehyde substance. 2

30—RUBBER AND ALLIED SUBSTANCES

C. C.

Concentration of latex by means of a centrifuge. O. B. Schrieke. *Algemeen Proefsta. A. V. R. O. S.*, Circ. No. 150, 9 pp.(1939).—S. describes the "Westfalia"-centrifuge for the continuous sepn. of rubber from crude latex. It has a high efficiency (92–8% rubber recovered from latex compared with 80–92% of other types). A disadvantage is that the rotor has to be changed and cleaned frequently as the pores close after 1.75 hrs.' use. About 200 kg. can be coned. in 1 hr. The content of the rotor is about 11 l. Latex samples that are hard to sep. can be coned. easily. Robert Simha 4

History of the statistic-kinetic theory of rubber-like elasticity. Typographical error in support of a priority claim. Edgar Wohlisch. *Z. physik. Chem.* **A184**, 416 18 (1939).—The statistic-kinetic theory of rubber-like elasticity was first developed by Wohlisch in 1926 and not, as given by Hawk and Neumann (cf. *C. A.* **33**, 1537[2]), in 1936. Meyer and Ferri first took up the theory in 1932 (cf. *C. A.* **29**, 4622[8]). Victor R. Deitz 5

Prepn. of adhesives [from synthetic rubber] obtained in U. S. S. R. (Tsvetkov) **13.** Preserving oxidizable substances [rubber] (Brit. pat. 508,442) **13.** Coating rubber-insulated wires (U. S. pat. 2,175,099) **13.** Elastic fabric [contg. rubber latex] (U. S. pat. 2,175,733) **25.** 6

Pigmented rubber hydrohalides. James B. Holden (to Wingfoot Corp.). U. S. 2,175,801, Oct. 10. Increased resistance to aging is imparted to products such as rubber-HCl films by mixing C black with them. U. S. 2,175,802 relates to a like use of Prussian blue. Cf. *C. A.* **33**, 1540[2]. 7

Porous rubber suitable for filter sheets or battery separators. Ernst A. Hauser (to Dewey and Almy Chemical Co.). U. S. 2,175,798, Oct. 10. A porous product is formed by a process which involves milling a mass comprising rubber, curing substances such as S, ZnO and mercaptobenzothiazole, and a proteinous volume-loading substance such as Ca caseinate and forming an article such as a filter sheet from the mass, curing the article, and subjecting the volume-loading substance to the action of a proteolytic enzyme, and leaching out the decompn. products. Starch and diastase also may be used. 8

Rubber hydrochloride dispersions suitable for making laminating films, etc. Herbert A. Winkelmann (to Marbon Corp.). U. S. 2,174,673, Oct. 3. A method of making dispersions of rubber-HCl in benzene, toluene, xylene, ethylene dichloride, etc., comprises fluxing rubber with a resin which is sol. in one of the solvents, until an intimate mixt. of rubber and resin is obtained, calendering the mixt. into thin sheets, treating the sheets with HCl in the absence of solvents for the resin and the rubber, whereby there is obtained an intimate mixt. of rubber-HCl and resin, and agitating the mixture of rubber-HCl and resin in a solvent for the resin selected from benzene, its homologs and ethylene dichloride. U. S. 2,174,674 relates to a compn. adapted to be vulcanized and molded or otherwise shaped by heat and pressure in articles of manuf., the compn. comprising a rubber-HCl, vulcanizing and HCl neutralizing ingredients, and a plasticizer for the rubber-HCl selected from phthalyl glycolates and glycol phthalates, the plasticizer being present in amts. of from about 10% to 100% by wt. of the rubber-HCl. 9

Making rubber soles, etc. Charles R. Keiser and Theodore R. Rike (to Rainbow Rubber Co.). U. S. 2,174,943, Oct. 3. A method of forming a composite rubber sole or the like involves diffusing a coherent layer of liquid latex in nonvulcanizable condition onto the surface of a transfer member or plate, drying it on the transfer member, applying the latter to a blank of vulcanizable rubber with the dried latex layer in contact with a surface of the blank, and uniting the materials by vulcanizing under heat and pressure so as to permit subsequent removal of the transfer member.

Rubber balls such as golf balls. Ernest O. Dieterich (to B. F. Goodrich Co.). U. S. 2,175,685, Oct. 10. Solid balls are formed mainly of unvulcanized rubber with an imperforate surface layer of vulcanized rubber.

Synthetic rubber-like material. Harro Hagen, Ingofroh Dennstedt and Wilhelm Becker (to I. G. Farbenind. A.-G.). U. S. 2,175,082, Oct. 3. A 1,3-butadiene polymerizate and a sulfide of an alkylated phenol such as a di-(*tert*-amylphenol)disulfide are used together, the sulfide serving as a stabilizing agent.

Rubber vulcanization. Albert M. Clifford (to Wingfoot Corp.). U. S. 2,175,792, Oct. 10. An *N,N'*-bis(1-thiothiazyl)quinonediimine is used as an accelerator.

Rubber vulcanization. Joy G. Lichty (to Wingfoot Corp.). U. S. 2,175,809, Oct. 10. As a vulcanization accelerator, use is made of carboxymethyl bis(dimethyldithiocarbamate) or other compd. of the general formula $(DS)_2CHCOOX$ in which D is an aliphatic thiocarbamyl radical and X is an org. amine radical.

Rubber-tire tread. John P. Tarbox (to Edward G. Budd Mfg. Co.). U. S. 2,171,438, Aug. 29. A bonding material in liquid form such as molten brass or latex is applied to granular material such as a sand or slag and the bonding material is then rendered less liquid, or solidified, and the grains encased in the bonding material are subsequently incorporated in rubber for the tire-tread manuf.

Rubber articles such as jar rings. Arthur F. Thenet (to Cupples Co.). U. S. 2,170,919, Aug. 29. A method is employed which comprises forming a vulcanized rubber article more than 10% harder than the predetd. hardness of the finished article, and more than 5% smaller than the predetd. dimensions of the finished article, thereafter enlarging and at the same time reducing the hardness of the vulcanized rubber article, the simultaneous operations being performed by subjecting the relatively small vulcanized article to a drastic treatment in oil for a period longer than 15 min., until it attains the predetd. hardness and dimensions of the finished article.

Covering tennis balls. Samuel G. Ball (to Dunlop Tire

and Rubber Corp.). U. S. 2,171,118, Aug. 29. Sections of a partly fulled cloth are applied to a rubber ball to cover it, and fulling of the cloth is subsequently completed.

Salts of 2-mercaptobenzothiazole. Ira Williams (to E. I. du Pont de Nemours & Co.). U. S. 2,170,670, Aug. 22. Compns. suitable for use in rubber comprise water-insol. heavy metal salts, such as the Zn or Pb salts, of 2-mercaptobenzothiazole, in finely divided form, the particles of which are coated with neutral inert water-insol. oily or waxy hydrocarbons such as paraffin (the coated salts being substantially dry materials tending to form soft lumps).

Vulcanization accelerators. Wingfoot Corp. Brit. 506,296, May 25, 1939. Rubber is vulcanized in the presence of the reaction product of a 2-mercaptoarylthiazole with a halo-dioxane or S analog thereof. Suitable compds. are those prepd. by the interaction of 2-mercaptoarylthiazole, preferably in the form of an alkali metal salt, with 2,3-dichloro- or 2-chloro-1,4-dioxane, 2-chloro-1,3-dioxane, 2,3-dichlorothioxane and 2-chloro- or 2,3-dichloro-1,4-dithiane.

Rubber vulcanization. Marion W. Harman (to Monsanto Chemical Co.). U. S. 2,171,305, Aug. 29. As a vulcanization accelerator, use is made of a reaction product of equimol. proportions of monochloracetamide and the Na salt of mercaptobenzothiazole.

Vulcanizing rubber. Harry L. Fisher (to United States Rubber Products Inc.). U. S. 2,170,191, Aug. 22. Vulcanization is effected by means of a quinoncimine compd. such as *p*-quinonedioxime and an oxidizing agent such as PbO_2 or MnO_2 incorporated in the rubber prior to complete vulcanization. Numerous examples are given.

Vulcanizing rubber. Norman R. Wilson and Arthur J. Lang (to Rare Metal Products Co.). U. S. 2,171,901, Sept. 5. Scorching during vulcanization in the presence of an accelerator is inhibited by the use of a compd. such as a hypochlorite or *N,N'*-dichloroazodicarboxamidine.

Preserving rubber. Albert M. Clifford (to Wingfoot Corp.). U. S. 2,173,711, Sept. 19. Rubber is mixed with a small proportion of a *sec*-tetrahydrofurfuryl aryl amine such as tetrahydrofurfuryl naphthylamine or tolylamine.

Articles such as rubber gloves. Albert E. Sidnell (to Seiberling Latex Products Co.). U. S. 2,173,734, Sept. 19. A method for making rubber gloves or the like comprises forming a smooth body portion for the glove including thumb and fingers by depositing one or more layers of liquid latex on a form, and forming over a portion of the gloves, including surfaces of the fingers and thumb, roughened surfaces or gripping surfaces, by depositing a layer of liquid latex contg. a granular material distributed therein in homogeneous mixt. over the portion of the gloves, the last-named layer being deposited by dipping the forms with fingers extending downwardly whereby the latex will flow uniformly about and between the fingers and vulcanizing the gloves.

Rubber-coated tie bands for use around packages, etc. John L. Lane (to Ralph H. Wilbur). U. S. 2,173,972, Sept. 26. A band of flexible material such as paper carries thin flexible rubber coatings comprising dried and coalesced rubber latex particles only on opposite faces of opposite marginal portions, such coatings presenting exposed rubber surfaces and being firmly cohesive under pressure but practically nonadhesive with the uncoated surface of the band (various structural and mfg. details being described).

Rubberized tie band suitable for binding packages. Ralph H. Wilbur. U. S. 2,173,989, Sept. 26. A band of flexible material such as paper carries thin flexible rubber coatings of dried and coalesced rubber latex particles only on opposite faces of opposite marginal portions, the coatings presenting exposed rubber surfaces and being firmly cohesive under pressure but practically nonadhesive with the uncoated surface of the band and the band is waxed on at least its faces immediately in back of those carrying the coatings, whereby when the band is placed in a stack with other similar bands, the coatings of one band will come into contact with the waxed faces of an adjacent band in the stack.

Paper carrier sheet for tacky rubber. Geo. W. Coggeshall (to S. D. Warren Co.). U. S. 2,173,097, Sept. 19. A strong tough paper web is deeply impregnated with a fluid compn. consisting essentially of a water-sol. org. adhesive such as a modified starch or casein and a plasticizer such as glycerol, and is provided with a surface coating of a flexibilized starch compn., and at least one surface of the web is subjected to friction-calendering to give it a glossy nonadhering character. Various compns. which may be used are described.

Apparatus for spinning hollow rubber filaments for coating wires. Heinrich Ziegner. Ger. 678,042-3, June 7, 1939 (Cl. 39*a*. 10.03). Addn. to 654,864 (C. *A.* **32**, 3666[8]).

Coating surfaces. Charles F. Lumb. Brit. 507,057, June 5, 1939. Surfaces are coated by prepg. rubber or a rubber compd. in powder form, with or without the addn. of a powd. filler, and spraying it upon the surface by means of a pistol, in which compressed air or gas is used to eject the powder, in a stream that passes through or adjacent to a flame of sufficient temp. to melt the material or render it plastic. The powd. rubber may be mixed with powd. bitumen or bituminous compd., or with a molding powder, e. g., PhOH-CH_2O. Specified fillers are $CaCO_3$, CaO, ZnO, powd. C, coke, SiO_2, Zn dust, cement and ciment fondu. Cu, $CuSO_4$, As or arsenious compds. may be added to produce an antifouling coating. A vulcanizing agent, e. g., S, with or without an accelerator, may be present in the mixt., or the mixt. may be ejected by means of a gas contg. S. Alternatively, the sprayed coating may be cold vulcanized after application.

Vulcanizer for retreading tires. James C. Heintz. U. S. 2,174,189, Sept. 26. Various structural, mech. and operative details.

Rubber vulcanization. Winfield Scott (to Wingfoot Corp.). U. S. 2,173,731, Sept. 19. A vulcanization accelerator is used which is obtainable by reaction, under water-eliminating conditions (such as by heating to 140–145°), of approx. equimol. proportions of mercaptobenzothiazole and the equimol. addn. product of CH_2O and diphenylguanidine or the like.

CHEMICAL ABSTRACTS

Vol. 34 FEBRUARY 20, 1940 No. 4

1—APPARATUS, PLANT EQUIPMENT AND UNIT OPERATIONS

W. L. BADGER

New distillation apparatus for laboratory use. Lennart Smith. *Kgl. Fysiograf. Sallskap. Lund, Handl.* **47**, No. 5, 1-24(1936)(in Swedish, German summary 23-4).—A lab. distg. column is described in which internal cooling (reflux) is obtained by passing liquid or gas into a condenser-tube extending downward through nearly the whole length of the column. Heated gas or liquid is drawn off from the bottom of the internal condenser through a small concentric exhaust tube. Surface is increased on the vapor side by means of fins or disks projecting from the tube walls. Two forms of app. are shown, one requiring glass-blowing, the other being readily constructed from ordinarily available materials. Comparative distn. curves are given for the binary mixts. ether-acetone, water-alc., benzene-CCl_4, chlorobenzene-bromobenzene, and Me benzoate-nitrobenzene. The curves indicate a much sharper sepn. of the 2 components than was obtained with a Hempel, Vigreux or Widmer column. 11 references. W. C. T.

A substitute for the laboratory food grinder. W. B. Davis. *Ind. Eng. Chem., News Ed.* **17**, 752(1939).—A "hopcher" (Waring Corporation, 1697 Broadway, New York, N. Y.) is described in which knives, rotating at high speed in a liquid, rapidly reduce the sample to a fine state of subdivision. W. C. Ebaugh

Small centrifuge tube filter. Theodore Perrine and Wm. Kump. *Ind. Eng. Chem., Anal. Ed.* **11**, 658(1939). A filter plate made from Pyrex tubing is ground to fit the shoulder of a small conical centrifuge tube. A length of tubing left connected to the plate serves as a handle and as a means of causing the liquid centrifugate to react. The app. is readily used at low temp. by introducing powd. CO_2 into the centrifuge. W. F. Bruce

Mechanically operated continuous liquid-extraction apparatus. Geo. W. Pucher and Hubert B. Vickery. *Ind. Eng. Chem., Anal. Ed.* **11**, 656-7(1939).—A modified Widmark extn. app. (*C. A.* **20**, 3602) is made by connecting 2 Erlenmeyer flasks by a wide base tube sealed into the sloping sides. The app. is filled on one side with material to be extd. and on the other with $NaHCO_3$ for collecting acids or an acid soln. for bases. The app. is rocked through 15°, about an axis below the connection, at about 2.5 cycles per min. Of 5 solvents EtOAc was the most effective for extg. citric acid and other acids extd. with difficulty. HNO_3 was extd. quantitatively in 24 hrs. when the soln. is at pH 1.0. C_6H_6 was shown suitable for extg. neotine. W. F. Bruce

Investigation of analytic balances and microbalances manufactured in U. S. S. R. V. A. Muller. *Trav. inst. métrol.* (U. S. S. R.) No. **19**(**35**), 4-12(1939).—The domestic industry supplies the demand for most of the precision scales of the more common types. Present practice is to build short-beam balances with consequent economy of material, smaller effect of temp. coeff. and shorter period of vibration. The beam is 14 cm. for a balance of 200-g. capacity. Cold-rolled alloys, low-zinc bronze and duralumin are satisfactory beam materials. Aluminum, widely used, is inferior. A number of balances and microbalances were investigated for beam mass inertia, location of basic points, center of gravity, distance from the knife edges, sensitivity, inequality of arms and period of vibration. In their indication constancy, accuracy of detail and assembly, Soviet scales are inferior to the foreign. B. Gutoff

Investigations in the field of precision balances. S. D. Gidaspov. *Trav. inst. métrol.* (U. S. S. R.) No. **19**(**35**), 12-23(1939).—A theoretical discussion of const.-sensitivity balances, isochronous balances, and control of scale sensitivity by observing the vibration period. B. G.

Investigation in the field of precision weighing. S. D. Gidaspov. *Trav. inst. métrol.* (U. S. S. R.) No. **19**(**35**), 23-8(1939).—In a modification of Gauss' method for detn., of the mass of a set of wts., they are placed on one pan, the standard is placed on the other, the balance is brought to equil. L_0 with an addnl. wt. (usually the rider, which does not have to be considered any more), the entire set of weights is then interchanged, one by one, and the mean balance point noted after each change. The difference between the means of two subsequent vibrations $L_n - L_{n-1}$ caused by the interchange of 2 weights P_n and Q_n will indicate the difference of these wts. The sensitivity is detd. at the beginning and the end of the weighing. The mass of the wt. P_n is detd. from $P_n = Q_n + {}^1/_2 R_n g + {}^1/_2 q_n$, where Q_n is the wt. of the standard, R_n is the difference between two positions of pointer $L_n - L_0$, g, scale sensitivity, q_n the added wt. The proposed system has the accuracy of Gauss' method, with the advantage of Mendeleev's, permitting the checking of the entire set in one operation. B. Gutoff

Investigation of standard hydrometers, sp. gr. 0.650 2.000. I. I. Kuznetsov. *Trav. inst. métrol.* (U. S. S. R.) No. **19**(**35**), 46-56(1939).—The Glass Blowing Corporation VIMS prepd., in 1930, three identical hydrometer sets, 19 each, covering the entire scale. The scale corresponds to a difference of 0.70, and has 140 unequal divisions, the smallest corresponding to 0.0005 unit d. The method of calibration is described. Tables show that the deviation is less than half of the smallest division, or 0.00025 g. B. Gutoff

Pycnometric method of calibration of standard hydrometers. M. D. Ippits. *Trav. inst. métrol.* (U. S. S. R.) No. **19**(**35**), 56-60(1939).—Because of the volatility of petr. ether, two pycnometers were used to check hydrometer readings. One, a cylinder-shaped bottle of 50 cc., had a 4-mm. capillary neck with bulb and ground-glass stopper. The second was 100 cc., spherical, with 4-mm. neck and wide mouth, with a ground-glass stopper. Details of the procedure are described. A table of results shows that the hydrometer corrections for the two pycnometers were identical. Boris Gutoff

A high-pressure differential manometer with magnetic transmission. G. E. Aristov. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 8, 45-8(1939). H. M. Leicester

[The Chandler Medal award to Thomas H. Chilton.] Anon. *Ind. Eng. Chem.* **32**, 23(1940).—Engineering in the service of chemistry. Thomas H. Chilton. *Ibid.* 23-31.—Chandler lecture. E. H.

Automatic effusiometer for determination of specific gravity of gases. Geo. V. Feskov. *Ind. Eng. Chem., Anal. Ed.* **11**, 653-4(1939); cf. Edwards, *C. A.* **11**, 2554.—Addn. of an automatic timer consisting of an elec. stop clock with Pt contact points in a Hg reservoir outside the effusion chamber improves the accuracy of the method and the ease with which detns. are carried out. The app. is not recommended for gases contg. H_2S. W. F. Bruce

A precision determination of the viscosity of air. J. A. Bearden. *Phys. Rev.* **56**, 1023-40(1939).—An instrument with a rotating inner cylinder gave the viscosity of air at 20° as (1819.20 ± 0.06)10^{-7} poises. A method is

described for prepg. torsion wires with const. characteristics. S. Bradford Stone

Metering liquids which are viscous or solid at ordinary temperature. B. Mironov. *Masloboino Zhirovoe Delo* **15**, No. 3, 38(1939).—Illustrated description of an electrically operated flowmeter. Julian F. Smith

A practical continuous liquid extractor. Fritz Reuter. *Australian Chem. Inst. J. & Proc.* **6**, 384–6(1939).—An app. is described for the continuous extn. of a wide range of liquid vol. (25 500 ml. and more). The same set-up can also be conveniently used for the evapn. of low-boiling solvents such as ether. For the extn. of larger vols. the use of longer and wider bottles with distributors to match is proposed. Robert Simha

Separation of liquid mixtures in the Clusius separation tube. H. Korsching and K. Wirtz. *Z. Elektrochem.* **45**, 662–3(1939); cf. *C. A.* **33**, 7643[1]. L. E. Steiner

Vacuum service in the chemical industry. A. E. Williams. *Engineering* **148**, 607–9(1939).—A review. E. H.

Rapid circulating dialyzer. A. R. Taylor, A. K. Parpart and R. Ballentine. *Ind. Eng. Chem., Anal. Ed.* **11**, 659(1939).—A double continuous-flow app. is described. A gas lift is used for circulating the soln. to be dialyzed. A bulb receiver is connected to a long dialyzing chamber designed to give a thin layer in contact with the membrane. Pressure from osmosis is impossible. The app. can readily be operated in a refrigerator. Protein solns. (25–150 cc.) were freed of 98% of salt in 9 hrs. with a min. of denaturation (cf. Aitken, *C. A.* **25**, 619). W. F. Bruce

Determining the diameters of openings in screen plates of rectifying columns. A. A. Grigor'ev. *Khim. Mashinostroenie* 8, No. 7, 8–10(1939).—In detg. the proper diam. of openings in screen plates of rectifying columns a sheet of material having the same compn. and thickness as that from which the screen is to be made is perforated with many holes of regularly varying diams., the sheet is then wetted with the liquid which is kept close to its b. p., and the largest hole which remains filled with the liquid is selected as the proper size. Owing to inaccuracies in constructing screen plates on a large scale the diam. selected should be about 10–20% less than that chosen in the above lab. expt. B. Z. Kamich

Operation and use of a centrifugal acid pump without a packing gland. W. Meinecke. *Chem. App.* **26**, 294–6; *Zellwolle u. deut. Kunstseiden-Ztg.* **5**, 244–5(1939).—The details of operation and construction of a packingless centrifugal pump are described. During rotation the shaft is hydraulically sealed; when not in motion, sealing is accomplished by metal-to-metal contact between a ring on the shaft and a ground seat in the casing. G. W. Stroebe

The preparation of compressed oxygen from liquid oxygen. A. Orlieck. *Chem. App.* **26**, 321–4(1939).—Methods and types of app. for the vaporization of liquid O are described. Storage and transportation problems are discussed. G. W. Stroebe

Capillary flowmeter with variable orifices. Johannes H. Bruun. *Ind. Eng. Chem., Anal. Ed.* **11**, 655(1939).—In place of interchangeable capillaries, a single large-bore capillary can be used in conjunction with different gage wires, which are inserted in the whole length of the capillary. With a capillary 60 × 1.1 mm. the range of gas flow from 0.2 to 7 l. per min. was covered, wires from 20 to 30 gage were used. Ease of cleaning the capillary is an important advantage. W. F. Bruce

Fluid flow through porous carbon. M. R. Hatfield. *Ind. Eng. Chem.* **31**, 1419–24(1939).—Flow rates were detd. through porous C over a superficial velocity range of nearly 600,000-fold, d. 1140-fold, viscosity 31,000-fold, pore diam. 40-fold and thickness 5-fold—nearly 2000 detns.; air, water, corn sirup soln., paraffin oil and glycerol were used. A "friction factor," $Dg\Delta P/2\rho LV_m^2 = f$, is plotted logarithmically against $DV_m\rho/\mu = Re$, where D is pore diam., g is gravity, ΔP is pressure drop, ρ is fluid d., L is thickness, μ is fluid viscosity, and V_m is estd. mean velocity through the pores. The units are ft., lb., and sec., but f and Re are dimensionless. When $8 \times 10^{-6} < Re < 4$, $f = 0.29/Re$, indicating streamline (viscous) flow (Darcy's law). Between the points $Re = 10$, $f = 0.035$, and $Re = 160$, $f = 0.0075$, the line is straight, the slope indicating turbulent flow. When $4 < Re < 10$, the line is curved, indicating gradual dissemination of turbulent flow throughout the varying sized pores. The max. deviation is about 40%. D is detd. by the method of Ruoss and others (cf. *C. A.* **30**, 6620[9]; E. W. Washburn, *Proc. Natl. Acad. Sci.* **1**, 115(1921)), measuring streamline flow of viscous liquids and computing D by a formula related to Poiseuille's law and involving void space. V_m is estd. by dividing the superficial velocity by the porosity (cf. *C. A.* **27**, 4660), which varies from 36% to 48%. Flow through porous media in general is briefly discussed. Twenty-five references. R. W. Higbie

Flow of liquids through beds of granular solids. Wm. H. Ward. *Engineering* **148**, 435–8(1939).—Data on the flow of water through 8 sands and gravels are correlated in a single plot; a friction factor and Reynolds no. are used and corrections are made for porosity by the method of Bakhmeteff and Feodoroff (*J. Applied Mechanics*, Sept. (1937), June (1938)). Reynolds no. varies from 1.2 to 5000, including streamline and turbulent flow. It is based on the diam. of a sphere of mean particle weight, which varies from 0.08 to 0.626 cm. Porosity varies from 0.356 to 0.462. R. W. Higbie

Flotation. H. Madel. *Chem. App.* **26**, 305–8, 324–6 (1939).—A review. G. W. Stroebe

Apparatus for luminescence analysis and its use for the examination of silicates. B. S. Shvetsov, M. A. Matveev and Ju. P. Simanov. *Keramika* **1939**, No. 8, 5–12.—An a.-c. Hg vapor-quartz lamp of 380–400 w. is equipped with a filter that transmits ultraviolet rays and with a device for microscopical observation. The app. can be used for detg. in slags to be used as rubble the stability against silicate decompn. due to the transition of β-2 $CaO.SiO_2$ to γ-2$CaO.SiO_2$. Stable slags give a homogeneous dark-violet or dark-brown (more rarely bright-violet) luminescence. Older slags show sometimes isolated gold-yellow or silver-white pads or efflorescences due to weathering. Unstable slags show a light breakage surface, multiple iridescent white-yellow and bright-yellow points on a bright-violet ground, sometimes also rust-brown pads with light-brown points. The method can be used also for detn. of the extent of mullitization of fused mullite ware, refractories, porcelain and other ceramic ware. E. E. Stefanowsky

Color testing. Tryggve Johansson. *Svensk Papperstidn* **42**, 529–34(1939).—App. used in testing colors by illumination is described. Wilhelm Segerblom

What diameter? What pressure? How many pounds of steam? W. F. Schaphorst. *Ind. Eng. Chem., News Ed.* **17**, 764(1939).—A nomographic chart of 3 scales answering the above questions when there is at least a 60% drop through the opening. Applications to typical problems are cited. W. C. Ebaugh

Arrangements and economic practice in continuous crushing and grinding. E. H. Fraser and A. N. Hambly. *Soc. Chem. Ind. Victoria, Proc.* **39**, 199–202(1939). E. H.

A newly developed spray drier for chemical industries. J. F. Kesper. *Chem. App.* **26**, 353–4(1939).—A spray drier in which the soln. is dispersed in the center of the drying chamber by 2 converging hot-air streams. The main drying air stream is introduced tangentially. Temps. up to 400° can be used. The soln. can be preheated and partially evapd. by contact with the outgoing air. G. W. Stroebe

The theoretical basis for the practice of drying technique, removal of fogs and humidification. P. Beckers. *Spinner u. Weber* **57**, No. 36, 2–6, 8, 10, 12(1939). L. S.

Lead-sodium alloy as a drying agent. Harold Soroos. *Ind. Eng. Chem., Anal. Ed.* **11**, 657–8(1939).—An alloy of 90 parts Pb and 10.5 parts Na is brittle and readily powdered, as well as safe to handle. It is as effective a drying agent as Na wire, but acts more slowly. Unused alloy can safely be decompd. with H_2O. W. F. Bruce

Heat exchange of gases at high pressures. A. B. Nefedov. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 8, 21–4(1939).—Data are reported for the heat exchange of 3:1 H_2-N_2

mixts. at 1–276 atm. and av. temp. 50–60° flowing through metal pipes. The usual laws are obeyed. H. M. L.

Using hot blast gases to blow out hydrogenation apparatus. A. Panyshev. *Maslobоino Zhirovoe Delo* **15**, No. 2, 19-20(1939).—Trial runs show that hot blast gases from a water-gas producer or other gas generator can be used for blowing out hydrogenation app. Gas connections for the purpose are described and illustrated. With a fuel bed 1 m. thick the full blast does not give excess air and the resulting gas contains no free O_2. Conditions for blowing out the app. with hot blast gases depend on the manner in which the gas was formed and may be governed according to the gas compn. as shown by analysis. J. F. Smith

Measurement of metal temps. of cracking-still tubes (Kaasa) **22**. Sediment indicator for testing liquids (U. S. pat. 2,177,060) **12**. Device for aerating liquids (U. S. pat. 2,176,558) **16**.

Achema-Jahrbuch, 1938/39. Berlin: Verlag Chemie g. m. b. H. Edited by **Herbert Bretschneider**. 387 pp.

Valve system suitable for reducing the pressure of various materials for chemical reactions, etc. Curt Räth (to Chemische Fabrik von Heyden A.-G.). U. S. 2,177,205, Oct. 24. Various structural, mech. and operative details.

Applying films such as paraffin to pouring rims of bottles to render them nondripping. Robert E. Ford (to Luther Ford & Co.). U. S. 2,177,625, Oct. 24. Various details of app. and operation.

Apparatus for dew-point determinations. Joseph C. Parkinson (to Pittsburgh Plate Glass Co.). U. S. 2,177,402, Oct. 24. There are used, in combination in app. for detg. the dew point of a fixed volume of gas contained in a double glazed window construction, a vessel provided with a thin metal face, which is designed to fit in intimate contact with one plate of the window construction, having a surface area materially less than that of the glass plate, a layer of insulating material substantially surrounding the vessel, an inlet tube connecting the central portion of the vessel with the atm., a freezing mixt., the temp. of which may be varied, contained in the vessel and indicating means for registering the temp. of the freezing mixt.

Vacuum rectifying column. Kenneth C. D. Hickman (to Distillation Products, Inc.). U. S. 2,176,498, Oct. 17. Various structural and operative details.

Solution suitable for removing oxygen from gases as in gas analysis. Dorothy Quiggle. U. S. 2,170,596, Aug. 22. An O-absorbing soln. is used of alk. reaction and contg. an alkali metal sulfide and an aromatic compd. such as pyrogallol, α-naphthoquinone, β-(chloromercuri)-anthraquinone, 1-chloro-2-anthraquinonecarboxylic acid, 1-mercapto-2-anthraquinonecarboxylic acid, the sulfide present in much greater amt. than the aromatic compd.

Separating gases such as carbon dioxide from mixtures. Leo Horvitz (to E. E. Rosaire). U. S. 2,177,139, Oct. 24. A component of a gaseous mixt. to be sepd., such as CO_2, is reduced to a solid phase of low vapor pressure which is collected; the reducing and collecting steps are repeated, and between the repeated steps such solid is revaporized as has failed to be collected in the preceding step. App. is described.

Centrifugal separators. John F. Tholl (to American Tool & Machine Co.). U. S. 2,176,440, Oct. 17. Various structural, mech. and operative details.

Steam separator and drier. Albert P. Pinto (to Novo Patents, Inc.). U. S. 2,176,098, Oct. 17. Various structural and operative details.

Separating fragmentary materials of different specific gravities. Victor Rakowsky, Ray W. Arms and Charles B. Hebbard (to Minerals Beneficiation, Inc.). U. S. 2,176,189, Oct. 17. An app. is used comprising a tank contg. a gravity-sepg. liquid medium of constantly increasing sp. gr. from the top downward and composed of a liquid and comminuted solids and wherein the lighter material floats and the heavier material sinks, means within the tank continuously removing in a current of the medium the heavier material together with some of the medium from a lower level in the tank, means sepg. the removed material with a small amt. of the solids of the medium clinging thereto from the thus removed medium, and means within the tank continuously vertically adjustable during operation for returning the thus sepd. medium otherwise unaltered to the tank.

Apparatus for air purification by spraying and reversal of flow to effect separation of impurities. Newton C. Schellenger (to Chicago Telephone Supply Co.). U. S. 2,177,289, Oct. 24. Various structural and operative details.

Apparatus for dispensing liquefied gases such as liquefied petroleum gas. Loyd J. White (to Southern Steel Co.). U. S. 2,177,620, Oct. 24. Various details of an app. with an underground storage tank.

Apparatus for storage and dispensing of liquefied gases such as liquefied butane and propane mixtures. Loyd J. White (to Southern Steel Co.). U. S. 2,176,829, Oct. 17. Various structural and operative details.

Apparatus for controlling the level of liquids, such as oil in a still. Paul E. Kuhl (to Standard Oil Development Co.). U. S. 2,176,741, Oct. 17. Various structural and operative details.

Bringing immiscible liquids such as oil distillates and alkali solutions into contact. Albert G. Schuessler and Robert W. Leslie (to Skelly Oil Co.). U. S. 2,176,806, Oct. 17. App. is described, and a method of treating a liquid with a heavier immiscible treating soln. which consists in maintaining a substantially const. body of treating soln. in a vessel, introducing a stream of the liquid into and below the upper level of the body of soln., passing the liquid through a packed zone, a portion of which extends into the body, whereby portions of the soln. are carried concurrently with the liquid through the packed zone to bring the two into intimate contact, sepg. the mixt. into its components in an unpacked zone, withdrawing the treated liquid, and returning the sepd. soln. to the body out of contact with the liquid being treated.

Apparatus for gas calorimetry. James G. Stewart. U. S. 2,177,267, Oct. 24. There are used together: means for supplying to the calorimeter app. the gas that is to be tested and the liquid medium employed for detg. the calorific value, comprising a first piston pump for producing a particular rate of supply of the liquid medium, a second piston pump for producing a rate of supply of the gas, which rate normally bears a fixed relation to the rate of liquid medium supply, and means effective upon one of the pumps for varying the output flow therefrom to compensate for local changes in atm. temp. and pressure.

Pyrometer tube. Benjamin J. Sweo. U. S. 2,177,046, Oct. 24. A unitary pyrometer tube comprises concentric tubular layers of semivitreous porcelain resistant to high temps., and an intermediate layer therebetween composed of vitreous porcelain which is impervious to gases so that it constitutes a seal for the pores in the semivitreous porcelain (all the layers being bonded by firing them together as a unit).

Forced-circulation evaporator. Philip B. Sadtler (to Goslin-Birmingham Mfg. Co.). U. S. 2,176,152, Oct. 17. Various structural and operative details.

Furnace-heated apparatus for drying wet granular materials such as sand. Wm. H. Golden. U. S. 2,177,404, Oct. 24. Various structural and operative details of a continuous drier.

Open-work tray for use in heat-treating furnaces. Henry H. Harris. U. S. 2,176,072, Oct. 17. Structural details of a bent-bar tray. U. S. 2,176,073 also relates to structural details of a tray for like use.

Apparatus for testing the tensile or compression strength of materials. John P. Sanner (to Tinius Olsen Testing Machine Co.). U. S. 2,176,722, Oct. 17. Various structural, mech. and operative details.

Shell and tube surface condenser. Ulrich A. Taddiken (to Westinghouse Elec. & Mfg. Co.). U. S. 2,176,475, Oct. 17. Various structural details.

Atomizing device suitable for use with cleansing liquids, etc. Rome C. Seyforth (to Shelby Metal Products Co.). U. S. 2,176,642, Oct. 17. Various structural and operative details.

Concentrating apparatus for air-conditioning solutions, etc. Harry F. Smith (to General Motors Corp.). U. S. 2,176,645, Oct. 17. App. suitable for treating solns. of glycerol, $CaCl_2$, etc., includes a heater for the circulating liquid, a motor and blower and a switch responsive to the d. of the liquid treated for controlling the operation of the motor and blower. Various structural and operative details are described.

2—GENERAL AND PHYSICAL CHEMISTRY

Organic matter in water of certain seas. V. G. Datsko. *Compt. rend. acad. sci. U. R. S. S.* **24**, 294–7(1939)(in English).—Analyses of water samples showed that the C and N contents of the Sea of Azov and the Caspian are higher than those of other seas investigated. The water of the Caspian is much more abundantly stored with org. C than the Sea of Azov but is poorer in N. The hydrographic reasons are briefly discussed. The water of the White Sea is richer in both org. C and N than are the ocean waters, and its C/N quotient is somewhat lower. The protein and carbohydrate contents are given in a table:

Sea	Protein mg./l.	Carbohydrates mg./l.	Total of carbohydrates + protein mg./l.
Caspian	3.1	11.0	14.1
Sea of Azov	3.9	6.0	9.9
White Sea	1.9	4.0	5.9
Black Sea	1.6	4.0	5.6
Greenland Sea	1.4	3.5	4.9

Relation between the chlorinity and the density of Caspian sea water. A. V. Trofimov. *Compt. rend. acad. sci. U. R. S. S.* **23**, 929–32(1939)(in English).—Expts. were made with a view to increasing the accuracy of calcg. the d. of Caspian sea water by means of its Cl no. The d. was detd. by the wt. pycnometer method at 0° and 25°. The Cl content was detd. by wt. titration of weighed samples of H_2O. The relation of chlorinity and d. is expressed by an equation of the 2nd order: $\sigma_0 = 0.036 + 2.090\ Cl - 0.0063\ Cl^2$, modified in the case of southern Caspian water artificially dild. with twice distd. H_2O as follows: $\sigma_0 = -0.132 + 2.101\ Cl - 0.0025\ Cl^2$. The relation between σ_0 and σ_{25} is: $\sigma_{25} = -2.808 + 0.933\ \sigma_0 + 0.0013\ \sigma_0^2$. Salinity is calcd. from the Cl no. by the equation $S = 0.14 + 2.36\ Cl$. 7 references. A. H. Krappe

Oxidizing activity and pH of brown sediments of the Barentz Sea. A. V. Trofimov. *Compt. rend. acad. sci. U. R. S. S.* **23**, 925–8(1939)(in English).—The upper layer (1–3 cm.) of stratum *A* was compared with the lower layer *C* (15–30 cm.) at 21 stations. The upper layer of stratum *A* oxidized quinhydrone in all cases but one (Δ varying from −5 to 54 mv.) (Δ = the difference between the potential of a quinhydrone electrode dipping into the buffered mud and its value in the pure buffer). The lower stratum reduced quinhydrone in all cases (Δ varying from −45 to −78, mean Δ being −65). Between the upper stratum of the lower reduced layer a difference in the values of Δ was observed in all cases, equal to 90–100 mv. The mean pH value for the upper stratum is 8.20, for the lower stratum 8.25. The presence of an acid streak in the profile of the brown mud is due to an active process of oxidation caused by the dissolved O_2 of org. matter or manganous and ferrous carbonates present at the sea bottom. 5 references. A. H. Krappe

Physical chemistry and chemical technique. Ludwig Holleck. *Z. ges. Naturw.* **5**, 148–51(1939). —A discussion of the important role that phys. chemistry plays as a binding link between physics and mathematics on one side and inorg. and org. chem. and biology on the other side. The recent developments of chem. technique offer in an increasing degree a definite goal for research and offer a basis for the development of new branches of science. W. R. Henn

Investigations on the conductivity of solid gelatin-dye phosphors. Lajos Gombay. *Math. naturw. Anz. ungar. Akad. Wiss.* **58**, 338–54(1939).—At room temp. the cond. increases with the concn. of the dye. Const. temps. (either high or low) had the same effects: the dye-phosphor loses its cond. within a short time. At higher temps. this effect is irreversible; at low temp. it is reversible. With a continuous and regular increase of temp. the cond. at first increases to a max., then diminishes and finally increases again owing to a new inner positive e. m. f. The increase of cond. increases with velocity of temp. increase, and the extreme values of cond.-temp. curves are at higher points with rapid temp. increase. Once heated dye-phosphor plates showed on reheating to 50° no cond. at all, from 50° to 100° low, and above 100° rapidly increasing conductivities. S. S. de Finály

Fluctuations, thermodynamic equilibrium and entropy. Edwin C. Kemble. *Phys. Rev.* **56**, 1013–23(1939).—Because of the large fluctuations found when the laws of thermodynamics are applied to microscopic systems, K. suggests replacing all statements that thermodynamics makes about individual systems with corresponding statements regarding ensembles of identically constructed independent systems similarly prepd. or subject to the same expt. L. E. Steiner

The assignment of uncertainties to the data of chemistry and physics, with specific recommendations for thermochemistry. Frederick D. Rossini and W. Edwards Deming. *J. Wash. Acad. Sci.* **29**, 416–41(1939).—For the comparison and appraisal of measurements made in different labs., for the purpose of estg. the uncertainty in the value of a phys. or chem. const., there should be adopted a uniform procedure for expressing the consistency of data. From a consideration of the definitions of precision and accuracy, and on the basis of the theory of probability, the procedures for ascertaining this are discussed. The examn. of one or more sets of observations, tests for functional concordance in measurements involving several magnitudes, and the propagation and combination of errors are considered for data known to be in statistical control. This is applicable to abs. or comparative measurements in general, and the example of thermochem. measurements is discussed in detail. J. W. Knowlton

A rule of coördination valency. Richard F. Robey. *J. Chem. Education* **16**, 514–16(1939).—The approx. coördination no. is half the difference between the effective at. no. of the simple cation and the at. no. of the following inert gas. The rule does not hold for certain alkali and

alk. earth metals, where space relations limit the coördination no. to 6 or less. Wm. E. Trout, Jr.

A simplified nomenclature for the proton-transfer concept of acids. Hubert N. Alyea, *et al.* *J. Chem. Education* **16**, 535–8(1939).—Tentative recommendations of the Comm. on Nomenclature of Acids, Bases and Salts, of the Division of Chem. Education of the Am. Chem. Soc. Approved terminology and superfluous or incorrect usage listed. Sixty definitions and a selected bibliography are included. Wm. E. Trout, Jr.

Remarks on the calculation of bond strengths. Milton Burton. *J. Chem. Phys.* **7**, 1072–5(1939); cf. *C. A.* **33**, 8094[1].—The hypothesis that predissocn. may be used to establish bond strength is shown to lead to incorrect conclusions. Values are derived from various C—C and C—H bond strengths. Bonds in free Ac and formyl radicals are weaker than in the stable compds. G. M. P.

New aspects on the cohesion of simple compounds. III. J. M. Stevels. *Rec. trav. chim.* **58**, 931–40(1939) (in English); cf. *C. A.* **33**, 4483[7,8].—The b. ps. of halogenated methane, ethane and ethene derivs. are calcd. as the sum of 3 effects; the London, Keesom and Debye effects. These effects are estd. to a higher approximation than formerly. The previous formula for the L. effect is generally satisfactory, a slight correction being made in a few cases. The formula for the K. effect is correct, whereas that for the D. effect is altered. With these alterations it is possible to predict trends in the b. p. of isomers of the same type. Agreement is found in all known cases. John E. Vance

Antiferromagnetism in some manganous compounds. Charles F. Squire. *Phys. Rev.* **56**, 922–5(1939).—The temp. dependence (300°K. to 40°K.) of the magnetic susceptibility of the following Mn^{++} salts was measured: MnO, MnS, MnSe, MnTe. A λ-point transition at low temps. makes the susceptibility break away from a Weiss-Curie law and decrease with lowering temps. Each salt has its characteristic transition temp., increasing with increasing mol. wt. Evidence for field dependence of the susceptibility and for magnetic hysteresis was found. An exchange force may be the cause of the transition from paramagnetism to antiferromagnetism. Bernard Lewis

Electrical conductivity as a function of temperature of some manganous compounds. Charles F. Squire. *Phys. Rev.* **56**, 960(1939); cf. preceding abstr.—When log resistance is plotted against temp. for MnSe, MnS and MnO a series of straight lines is obtained. MnTe has a rounded max. at 290°K. G. M. Petty

Internal rotation and dipole moment in succinonitrile. Geo L. Lewis and Charles P. Smyth. *J. Chem. Phys.* **7**, 1085–93(1939).—A new heterodyne-beat app. was used to det. the dipole moments of MeCN and of $NC.C_2H_4.CN$ in soln. Dielec. consts., ds. and polarizations are tabulated for solns. of MeCN in C_6H_6 at 25° (c_1 = 0–0.20), MeCN in PhMe at −60 to +60° (c_1 = 0.013–0.071); $(CH_2CN)_2$ in PhMe at −90 to +90° (c_1 = 0–0.044). The height of the potential barrier which restricts rotation about the C—C bond in $(CH_2CN)_2$ is calcd. to be 1.2 ± 5 kg.-cal. G. M. Petty

Determination of the velocity of sound in a gas; application to analysis of mixtures of helium, oxygen and nitrogen. Wm B. Dublin, Walter M. Boothby and Marvin M. D. Williams. *Science* **90**, 399–400(1939).—An app. for detg. the velocity of sound in a gas was constructed which is particularly suited for mixts. of He, N and O. It is possible to det. the percentages of He and N in the whole mixt. with an accuracy of approx. ±1.0%. A. B. G.

Tension of lithium vapor between 462° and 642°. Marguerite Maucherat. *J. phys. radium* **10**, 441–4(1939). —See *C. A.* **33**, 3225[4]. H. Game

The coefficient of thermal diffusion of methane. Alfred O. Nier. *Phys. Rev.* **56**, 1009–13(1939).—The coeff. of thermal diffusion of CH_4 was calcd. from the observed sepn. of the isotopic gases, $C^{12}H_4$ and $C^{13}H_4$, under a temp. gradient. L. E. Steiner

The van der Waals potential in helium. H. Margenau. *Phys. Rev.* **56**, 1000–8(1939).—Theoretical. The van der Waals potential in He is calcd. from its at. structure. L. E. Steiner

The limiting volumes of oxygen and hydrogen. G. P. Luchinskiĭ. *J. Gen. Chem.* (U. S. S. R.) **9**, 1310–12 (1939).—The limiting vols. of O and H are calcd. by means of the limiting vols. of their compds. As initial values for the calcn. of the limiting vol. of O were taken the limiting vols. of SO_2, SO_3, $SOCl_2$, SO_2Cl_2, $S_2O_5Cl_2$, $S_3O_7Cl_4$, $COCl_2$ and $POCl_3$ whose values of ω were 0.5065, 0.5147, 0.5329, 0.5114, 0.5267, 0.5231, 0.5606 and 0.5352, resp. If for the compd. Q_xO_y the mol. limiting vol. is ωM (if the additivity rule holds true) the atomic limiting vol. of O $\omega_0 A_0$ can be calcd. for $\omega_0 A_0 = (1/y)(\omega M - x\omega_q A_q)$, where A is the at. wt. The results of the calcn. of the at. limiting vol. of O checked sufficiently well with one another. The limiting vol. of O was also calcd. from the crit. vol. of elementary O. The mean deviation of the $\omega_0 A_0$ values obtained from the 8 different substances was +9.31% and it was equal to 8.67 from which the limiting vol. of O ω_0 was found to be 0.5419. The limiting vol. of water was used for the calcn. of the limiting vol. of H. The fluidity of water obeys the rule of Bachinskiĭ only in the region of sp. gr. from 1.03 and higher. The mol. limiting vol. of water was calcd. to be 17.47 from which the at. limiting vol. $\omega_H A_H$ was 4.40 and the limiting vol. of H ω_H = 4.365. One curve, 2 tables and 6 references. W. R. Henn

Phenomenological thermodynamics of moving matter. D. van Dantzig. *Physica* **6**, 673–704(1939)(in English). —Thermodynamics and hydrodynamics of moving matter are presented in relativistically invariant form, with special reference to perfectly perfect fluids. If a flowing imperfectly perfect fluid such as liquid He is subjected to a temp. gradient, a relativistic effect gives rise to internal friction. The effect is too small to be detected. G. M. Murphy

Viscosity of liquid ammonia. C. J. Plank and Herschel Hunt. *J. Am. Chem. Soc.* **61**, 3590–1(1939).—By use of a closed system (app. illustrated) the d. (g./cc.) and viscosity of liquid NH_3 (av. g./cm. sec.) are detd. to be at 5° 0.63197, 0.001618; at 15° 0.61821, 0.001457; at 25° 0.60427, 0.001350. The app. was calibrated with CS_2 and CCl_4 for which d. and viscosity are given for 5, 15 and 25°. C. J. West

The surface-tension isotherms of binary liquid systems. N. A. Trifonov. *Trudy Saratov. Avtomob.-Dorozhn. Inst. im. Molotova* **1938**, No. 4, 381–401; *Khim. Referat. Zhur.* **2**, No. 4, 26(1939).—By considering a system to be normal if its components do not change their mol. conditions on mixing and by adding to this definition the requirements (specific for surface tension) of the proximity of the dipole moments of the components, T. concludes that the surface-tension isotherm of such a system can be best expressed by the formula of Stakhorskiĭ $\sigma = \sigma_1\sigma_2/[\sigma_1(1 - X) + C_2X]$. This formula was verified on a no. of systems. According to the formula the isotherm is expressed by a curve that is curved downward, toward the axis of the components. The surface-tension isotherms of a system contg. a decompg. assocd. component lie below the isotherm of the normal system. Singular curves were obtained for rational systems from the isotherms of the first two types. These curves are always branched out toward the abscissa axis. The singular point forms either a max., a min. or a nodal point, depending on the relation between the values of the surface tension of the compd. and the components. The isotherms of the irrational systems correspond to the same types as the rational isotherms, but their extremes or their transition points are rounded, and they do not correspond to the rational compn. of the components. A no. of examples of systems are presented that illustrate the types of isotherms described. W. R. Henn

The structure of liquids. Joseph O. Hirschfelder. *J. Chem. Education* **16**, 540–4(1939).—The Eyring theory (*C. A.* **30**, 3304[8]) of liquids, based on the space in which a mol. is free to move when its neighbors are fixed, is developed in terms of elementary thermodynamics and a simple picture. An equation of state is derived, $(p + a(T)/V^2)(v - 0.7816b^{1/3}V^{2/3}) = NkT$, where v is the free

vol. and the remaining symbols have their usual significance. This is a limiting form of van der Waals' equation corrected for close packing. The Hildebrand (cf. *Solubility of Non-Electrolytes*, *C. A.* **30**, 2478[8]) and Trouton rules for vapor pressure and entropy change on melting, and the temp. coeff. of viscosity are explained.
Wm. E. Trout, Jr.

The nature of the anomalous physical properties of thin silver films. A. T. Ashcheulov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 122–5(1939) (in English).—Ag was evapd. *in vacuo* onto glass, fused quartz, KCl and NaCl in layers of varying thickness. The absorption of transmitted light by these films was then detd. as a function of the wave length. When the Ag was deposited on a base kept at room temp. the max. absorption for thin films (1 mμ) was at a wave length of 430–440 mμ; with increase in the thickness of the layer the max. absorption shifts toward longer wave lengths. When the base was heated to 300–350° during the deposition, Ag layers 10–15 mμ thick were required to give max. absorption at a wave length of approx. 440 mμ. Such films on standing gradually revert to the condition of the cold-deposited ones; vapors of I or Br accelerate this change, without forming AgI or AgBr in appreciable amts. The results prove that both types of films have a colloidal rather than an amorphous structure.
T. H. Dunkelberger

Cathode-ray investigation of thin layers formed on some single crystals. II. Molybdenum oxide deposited on molybdenite by sublimation of MoO_3 in vacuum. Ryozi Ueda. *Proc. Phys.-Math. Soc. Japan* **21**, 517–23(1939) (in English); cf. *C. A.* **33**, 4476. Thin films of MoO_3 were formed on cleavage faces of molybdenite or polished surfaces of Au, Ni or Cu, held at a temp. t, by sublimation in a vacuum, and the structure of the films was ascertained by electron-diffraction patterns obtained at grazing incidence. At t = 20–100°, diffuse rings are obtained. On molybdenite at 100–350° an oxide probably between MoO_3 and MoO_2 is found, and shows a fiber-like structure; at 350–490°, cryst. MoO_2 forms, extra spots showing the presence of a superlattice. On the metals, ring patterns only are obtained showing lack of orientation; on Au and Ni, the intermediate oxide is indicated at t = 100–350°, MoO_2 being found at 350–490°; on Cu, MoO_2 is formed over the whole range 100–490°.
A. O. Allen

The electrical breakdown strength of ionic crystals as a function of temperature. R. C. Buchl and A. Von Hippel. *Phys. Rev.* **56**, 941–7(1939).—It is shown that, at least in ionic crystals like KBr, a very steep increase of breakdown strength with temp. occurs in the lower temp. range, in contrast to the general belief that the breakdown strength of an insulator is const. in the lower temp. range and decreases rapidly at high temps., indicating thermal breakdown. This new phenomenon is apparently analogous to the temp. coeff. of the resistance in metals and it allows a decision between the different theories of breakdown proposed.
Bernard Lewis

Penetration of the ions of metals into transparent crystals of basic halides. S. A. Artsybyshev. *Trudy Fizicheskogo Inst.* **1**, 5–70(1938); *Khim. Referat. Zhur.* **2**, No. 2, 2–3(1939).—The penetration of the ions of Au, Ag, Cu, Ni, etc., into NaCl and KCl crystals was investigated. Cases were found from ions that were immobile in the crystals to ions possessing as great a mobility as those in aq. solns. Pt is an example of an ion that cannot move in the cryst. lattice. In some compds. the metal ion cannot move in the crystal, but the Cl sepg. at the anode reacts with the metal of the anode forming a Cl compd. This compd. gives an easily fusible mixt. with rock salt, the crystal is fused, and the metal of the anode flows into the cavity formed. Some metals can penetrate the crystals of the basic halides, causing a local destruction of the lattice with the formation of the corresponding Cl salts. The ions of some metals (Bi and Fe) penetrate the crystal and are sepd. in the form of mech. admixts. The cryst. lattice is destroyed in this place, and the metallic ions coagulate, forming a particle of the fused metal. At high temp., Au ions penetrate easily the crystal in which they are mobile, but the system is unstable on cooling. At a comparatively low temp. the ions of the metal can also penetrate the crystal forming a system that is stable at all temps. The theories of the mechanism of the movement of the ions in the cryst. lattice are discussed.
W. R. Henn

The crystal structure of cesium fluorochromate. J. A. A. Ketelaar and E. Wegerif. *Rec. trav. chim.* **58**, 948 (1939) (in German); cf. *C. A.* **33**, 1567[7].—The dimensions of the unit cell of $CsCrO_3F$ are a = 5.71[5] ± 0.005 A., c = 14.5 ± 0.1 A. The unit cell contains 4 mols. The structure is isomorphous with the K salt.
John E. Vance

Crystal structure of acid compounds of graphite. W. Rudorff. *Z. physik. Chem.* **B45**, 42–68(1939); cf. *C. A.* **32**, 8232[8].—X-ray study was made of the crystal structure of the compds. of graphite with H_2SO_4, H_2SeO_4, HNO_3 and $HClO_4$.
G. M. Murphy

X-ray study of polymetatelluric esters. Marcel Mathieu and Cécile Stora. *Compt. rend.* **209**, 834–6(1939).—The amorphous polymetatellurates (cf. Patry, *C. A.* **30**, 5521[9]) of Me, Et, Pr, Bu, Am and iso-Pr, iso-Bu and iso-Am were examd. by x-rays by Guinier's method (*C. A.* **31**, 4200[3]). Their amorphous structure is confirmed and the progressive changes tightening of the concentric rings—with increasing length of the hydrocarbon chain are described.
C. A. Silberrad

The adsorption of hydrogen by copper dispersed in calcium oxide. John R. Lewis, Lawrence J. E. Hofer and Howard Whitehead. *J. Am. Chem. Soc.* **61**, 3580–3 (1939).—The adsorption was measured at 650 mm. and over a temp. range of 273–707° A. The data indicate that Cu, dispersed in CaO, is a better adsorbent for H than is pure Cu. In general the activated adsorption of H on CaO and on Cu dispersed on CaO resembles the adsorption of H on MgO and on Cu dispersed in MgO. Cf. *C. A.* **32**, 4032[2].
A. B. Garrett

The structure of the adsorption layer and the adhesion of microscopic particles. A. v. Buzágh. *J. Phys. Chem.* **43**, 1003–14(1939). See *C. A.* **33**, 2013[8].
W. B. K.

Theory of nondissolving volume. II. B. V. Deryagin. *Colloid J.* (U. S. S. R.) **5**, 605–11(1939); cf. *C. A.* **33**, 8468[1]. With Bakker's theory of the structure of surface layers and the Gibbs adsorption theorem as a basis a relation is derived between the "nondissolving" vol. and the concn. of the substance the neg. adsorption of which is measured. The expts. used for checking the theory give a curve of a predicted shape but an impossible value for the const. involved (vol. of the solute in the soln.).
J. J. Bikerman

Adsorption of the ions of barium, sodium and lithium by glauconite in relation to the pH of the equilibrium solution and the concentration of the ion. E. A. Materova. *J. Gen. Chem.* (U. S. S. R.) **9**, 1274–8(1939). The exchange of Ba^{++}, Li^+ and Na^+ ions on glauconite was investigated by potentiometric titration. Titration curves were obtained electrometrically in the presence and in the absence of glauconite under identical conditions. In general for all cases an increase of the pH of the soln. increased greatly the exchange ability. At pH 7–11 the dependence was nearly linear. The exchange of Li^+, Na^+ and Ba^{++} justifies the supposition of the electromotive activity of H^+ toward glauconite. The adsorption of H^+ is of a "chem." character whereas the adsorption of the metallic cations is of an electrostatic adsorption nature. The effect of the concn. of the ion on the adsorption curve agreed with Frumkin's theory of the electromotive-active ion. The effect on the nature of the ion on the adsorption agreed with the lyotropic series. One diagram, 6 tables and 8 references.
W. R. Henn

Interaction of casein with aqueous solutions of aniline and pyridine. A. Ya. Korolev and V. A. Vilenskiĭ. *Compt. rend. acad. sci. U. R. S. S.* **24**, 266–9(1939) (in German).—Casein sol was brought into contact with aq. solns. of aniline and pyridine, resp., through a collodion membrane (denitrated with alc. $(NH_4)_2S$ soln.) until equil. was reached. From the change in concn. of aniline and pyridine, resp., detd. by the interferometer, the amts. taken up by the casein were calcd. Casein takes up aniline and pyridine by (1) salt formation and (2) sorption.

When K caseinate was brought into contact with pyridine solns. through the membrane, salt formation with the pyridine was suppressed and values for sorption alone were obtained. Results from casein sol and aq. pyridine solns. show that both water and pyridine are taken up by the casein, the ratio of sorbed water to sorbed pyridine increasing rapidly with increase in pyridine concn. in the soln. Casein swells in water or pyridine, but dissolves in aq. pyridine soln. George Ayers

Aging and formation of precipitates. XXX. The determination of the specific surface of silver bromide by the radioactive and dye methods. I. M. Kolthoff and A. S. O'Brien. *J. Am. Chem. Soc.* **61**, 3409–14(1939); cf. *C. A.* **33**, 5722[7].—Radioactive bromide is rapidly incorporated into well-aged AgBr when a soln. of the former is shaken with the solid. Adsorbed wool violet and methylene blue limit the exchange between soln. and solid to the surface layer only, and are suitable for the detn. of the sp. surface of AgBr. The amt. of dye adsorbed from a soln. contg. an excess of Ag is twice as great as that from a soln. contg. an excess of bromide. **XXXI. The aging of silver bromide.** *Ibid.* 3414–19.—The aging was followed by the wool violet and the radioactive methods. The speed of aging increased with increasing soly. of the ppt., but when the soly. reached a certain min. value, further decrease of the soly. did not affect the still fairly large speed of aging. Evidence is presented to indicate that this relatively rapid aging is due to a thermal aging of AgBr which also occurs in the dry state even at room temp. A. B. Garrett

Oriented coagulation in aerosols. III. Physical strength of aerosol sediments. D. Beischer. *Kolloid-Z.* 89, 214–19(1939); cf. *C. A.* **32**, 2402[8].—A method is given for the exptl. detn. of the breaking strength of thread-like aggregates of colloidal particles in a gaseous medium. The results obtained are compared with values calcd. by the method of Hamaker (*C. A.* **32**, 3219[1]) assuming exclusive action of the London-van der Waals forces between two spherical particles. In several cases these theoretical values agree fairly closely with the exptl. results and in these cases the breaking strength can be ascribed primarily to the London-van der Waals forces. In other cases in which the measured values are considerably greater than those calcd. according to Hamaker, either a cementing of the sep. particles by surface diffusion or the effect of addnl. elec. forces between polar particles must be assumed, according to the system being investigated. 13 references. A. L. Kibler

The use of ultrasonic energy for dispersion processes. Preparation of aqueous emulsions without the use of a stabilizer. A. A. Morozov. *Byull. Ivanovo Nauch. Issledovatel. Inst.* **1938**, No. 4–5, 105; *Khim. Referat. Zhur.* 2, No. 4, 19(1939).—Paraffin emulsions were prepd. without addn. of stabilizers in an ultrasonic field. With increasing quantities of paraffin, the concn. of the emulsion reached a max. at a proportion of 1.1 by wt. of the components of the mixt. The concn. of emulsion reached 0.4% on irradiation for 40 min. The degree of dispersion (1–5 μ, with a predominant diam. of the particles of 1.5 μ) increased simultaneously. The concn. increased nearly twofold with an increase of the intensity of the ultrasound, produced by increasing the tension on the quartz plate from 1.6 to 2.2 kv. Increased concns. of emulsions were obtained in the following order: 2% Na acetate < 7% C_2H_5OH < 0.5 *N* Na citrate < 4% formalin < distd. water < 10% glycerol < 10% acetone < 10% C_3H_5OH. W. R. Henn

The protective action of gelatin toward the hydrosols of metallic silver and of silver sulfide. A. A. Titov. *Kino-Foto-Khim. Prom.* **1938**, No. 9, 44–50; *Khim. Referat. Zhur.* 2, No. 3, 129(1939).—Very small concns. of gelatin increase the velocity of coagulation, whereas large concns. decrease the velocity of coagulation of Ag and Ag_2S sols. The protective action on the sols of Ag_2S depends to a considerable extent on the grade of gelatin, whereas all grades of gelatin exert practically the same effect on the sols of Ag. The protective action depends not so much on the gelatin substance as on impurities which possess the ability of "elective" protection in regard to Ag sols. The protective action gradually decreases with decreasing pH; at values of pH below the isoelec. point, gelatin exerts on both sols a sensitizing rather than a protective action. Up to values of pH = 4.35 gelatin coagulates Ag_2S sols. At pH > 4.7 the effect of H-ion concn. is much smaller for Ag sols than for Ag_2S sols. This fact points to an effect of adsorption in the phenomenon of protection. W. R. Henn

The theory of electrokinetic phenomena. Wm. Horwitz. *J. Chem. Education* **16**, 519–35(1939).—A review with 45 references. Wm. E. Trout, Jr.

Experimental investigations on laminar systems. Electrophoresis of thin films of metal sulfides and metal hydrates on the surface of water and solutions. S. G. Mokrushin and Z. G. Sheina. *Colloid J.* (U. S. S. R.) **5**, 707–15(1939).—Islets of thin films of CuS, As_2S_3, Sb_2S_3, Bi_2S_3, PbS, ZnS, Ag_2S, $Al(OH)_3$, $Fe(OH)_3$, $Zn(OH)_2$, or $Cu(OH)_2$, particles of paraffin wax, stearic acid, S, Al, or Mg, or droplets of petroleum jelly were placed on a water surface inside a paraffin wax ring, and Pt electrodes inserted outside the ring. The particles moved to one of the electrodes but neither the direction nor the rate of movement was const. No allowance for the movement of water was made. J. J. Bikerman

Thermostatics and dynamics of drying of disperse systems. A. K. Skryabin. *Colloid J.* (U. S. S. R.) **5**, 673–82(1939).—From equations given in S.'s book (Study of the Drying of Peat, 1936) the equation $dW/dt = -m(P_\infty - P_c)\tanh K(W - W_c)$ is deduced, in which t is time, W the amt. of liquid in the body, P_∞ the vapor pressure of the free liquid, P_c the pressure of the vapor in equil. with a unimol. layer of liquid on the particles of the disperse body (P_c is also supposed to be the vapor pressure in the air used for drying), W_c the amt. of liquid in the air-dry body, and m and K are consts. The equation agrees with exptl. results obtained in the course of drying peat. J. J. Bikerman

Surface solubility of clay particles. V. S. Sharov. *Colloid J.* (U. S. S. R.) **5**, 571–83(1939).—Surface soly explains the chem. and colloidal behavior of clays better than exchange adsorption. It also accounts for the plasticity of clay moistened with H_2O while mixts. of clay with apolar liquids are not plastic. J. J. Bikerman

Effect of the pH of the solution on the sedimentation of clays. A. S. Korzhuev and Z. L. Borisova. *Colloid J.* (U. S. S. R.) **5**, 475–82(1939).—One part of clay was shaken with 5 parts of H_2O, and the sedimentation of the suspension obtained was observed. Some clays sediment at once, while others produce a gradually increasing deposit. The effect of the pH is not uniform although strong acids usually accelerate, and strong alkalies retard, the sedimentation. J. J. Bikerman

Dependence of the swelling of clays upon the pH of the solution. A. S. Korzhuev and Z. L. Borisova. *Colloid J.* (U. S. S. R.) **5**, 667–72(1939); cf. preceding abstr.—The swelling of clays increases with the amt. of small particles (below 10^{-4} cm.) in them. In NaOH or HCl it is little affected by the pH between 3 and 11, and in AcOH-NaOH buffers between 5 and 9; in strongly acid or strongly alk. soln. it is larger than in neutral ones. J. J. B.

Dispersion of indanthrene pigments in the supersonic field. S. S. Tumanskii and Ch. Maksimova. *Colloid J.* (U. S. S. R.) **5**, 517–24(1939); cf. *C. A.* **33**, 6116[6].—Sedimentation curves of pigments dispersed in H_2O by the app. described (cf. *C. A.* **33**, 8470[4]) are given. In supersonic field a higher dispersity is achieved than in a colloid mill. There is no difference between tech. and pure specimens of indanthrene yellow *gk* and yellow *g*. The dispersity of chloroindanthrene is increased by sulfonated fatty acids. J. J. Bikerman

General chemistry of colloid-colloid reactions. VIII. Mechanism of protection by some higher carbohydrates. Wo. Pauli, J. Szper and St. Szper. *Trans. Faraday Soc.* **35**, 1316–27(1939); cf. *C. A.* **34**, 6674.—Gold, Congo blue, dextrin, starch, gum arabic and Night Blue sols were highly purified by electrodecantation. Gold sols, both spark-dispersed and those obtained by reduction with

alc., were distinctly protected by means of dextrin, but not completely, against KCl, $BaCl_2$ and $La(NO_3)_3$, least against the KCl. The highly purified gum arabic sol has a pronounced protective effect on Au sols against electrolytes and freezing; when present in a final concn. of 0.001% it completely protects the reduction Au sols against KCl, $BaCl_2$ and $La(NO_3)_3$. The spark-dispersed sols were protected by 0.01% of gum arabic final concn. No protective effect of electroneg. Congo blue sols by dextrin, gum arabic or sol. starch sols was obtained. However, Congo blue sols can be protected with gum arabic if the latter has previously been allowed to take up multivalent ions such as Ba, Mg or La. The role played by the surface groups of the particles in colloid-colloid reactions is emphasized and mechanisms for the protective effects are discussed. Victor R. Deitz

Dispersoid and high-molecular systems. A. V. Dumanskiĭ. *Colloid J.* (U. S. S. R.) **5**, 585–604 (1939).—The difference between sols and solns. of high-mol. substances is pointed out. Some methods of detg. the degree of dispersity, the shape, and the solvation of high-mol. substances are discussed; neither the viscosity nor the osmotic pressure gives the correct value for solvation. J. J. B

The density, thermal expansion, vapor pressure and refractive index of styrene, and the density and thermal expansion of polystyrene. Winton Patnode and W. J. Scheiber. *J. Am. Chem. Soc.* **61**, 3449–51 (1939).—The d. *vs.* temp. graphs for resinous polystyrene consist of 2 straight lines that intersect, which indicates that at the temp. corresponding to this point there is apparently a fundamental change in the structure of the polymer. The bilinear thermal expansion of polystyrene, the sharp transition temp., and the closely accompanying sharp "high elasticity temp." all point to the conclusion that polystyrene is a body of fairly definite compn. and structure. The d., thermal expansion, vapor pressure and n of carefully purified styrene are given. A. B. Garrett

Structure and solvation of cellulose nitrate particles. G. V. Lipatova and S. M. Lipatov. *Colloid J.* (U. S. S. R.) **5**, 647–54 (1939).—Cellulose nitrate was sepd. into 4 fractions by a gradual pptn. with H_2O. Fractions showing high viscosity in $PhNO_2$ solns. have a high temp. coeff. of viscosity, while the η of $PhNO_2$ solns. of other fractions is less affected by temp. As the temp. coeff. of solvation ought to be const. for various fractions it follows that the η is not connected with solvation and presumably depends on disaggregation of micelles. The ratio of viscosities of 2 fractions in various solvents ($PhNO_2$, $COMe_2$, and MeOH) is also different. J. J. Bikerman

Swelling of xerogels and powdered disperse substances in the course of sorption of water vapors. M. V. Chapek and P. V. Zhuravel. *Colloid J.* (U. S. S. R.) **5**, 541–53 (1939).—See *C. A.* **33**, 8083[6]. J. J. Bikerman

The nature of solutions of lyophilic colloids. S. M. Lipatov. *Colloid J.* (U. S. S. R.) **5**, 613–38 (1939).—The theory (cf. Staudinger, *C. A.* **32**, 3236[6]; Deryagin and Kusakov, *C. A.* **32**, 3235[2]) ascribing to lyophilic colloids a high degree of solvation disagrees with the fact that the activation energy of swelling is neg. whereas the energy of solvation is pos.; the swelling is not due to, and is no proof of, solvation. The lyophilic sols are not solns. of macromols.; they show the change typical for colloids from sol to sol possessing a structure, to gel, and then a syneresis. In contrast to mols. the particles of a lyophilic sol can adsorb mols. from solns.; thus large micelles of gelatin adsorb and are peptized by highly dispersed gelatin; the viscosity of mixed gelatin solns. is not additive (contrary to Staudinger's rule). A substance forms lyophilic sols if a part of its surface has a higher, and the rest a lower, affinity for solvent than for the substance itself; therefore the dispersity of a substance in its sols depends on the solvent. J. J. Bikerman

Stabilization of suspensions by fractions of gelatin and agar. P. M. Lapin and S. M. Lipatov. *Colloid J.* (U. S. S. R.) **5**, 683–90 (1939); cf. preceding abstr.—Less sol. fractions of gelatin and agar-agar stabilize ZnO suspensions better and are adsorbed by ZnO powder to a greater extent than more sol. fractions. The stabilizing effect of gelatin increases in the course of its aging or after a heating at 100°. Aging of agar has no effect. The heat of adsorption of gelatin by ZnO is greater for less sol. or for preheated gelatin than for untreated gelatin. These results agree with L.'s conception of a competition between the affinities of colloid particles for solvent and for adsorbent; when the first affinity is small the adsorption is favored. J. J. Bikerman

Composition of the colloids of the diffusion sap of beetroot. E. F. Simonova. *Colloid J.* (U. S. S. R.) **5**, 723–31 (1939); cf. Kharin, *et al.*, *C. A.* **33**, 9698[8].—The ppt. obtained at mixing diffusion sap with EtOH contains 24% of pectic substances (detd. as furfuraldehyde), 24% of proteins (from a detn. of N), and 25% of ash; the rest are org. acids, phytosterin, lecithin, saponin(?), etc. A part of the ash constituents is bound to the pectic substances and therefore belongs to colloids, and a part is bound to org. acids and is truly dissolved in the sap. The ash content is unaffected by the pH of the sap and by the ratio EtOH: sap. J. J. Bikerman

Structure and physicochemical properties of surface layers of highly polymerized compounds. II. Surface properties of agar and starch gels. V. A. Pchelin. *Colloid J.* (U. S. S. R.) **5**, 717–22 (1939); cf. *C. A.* **33**, 7645[8].—Drops of H_2O in air or C_6H_6 and of C_6H_6 in H_2O were placed on the surface of dry or swollen gels of agar and starch. The contact angles are slightly affected when water and benzene exchange their position and almost unaffected when the gels are kept in benzene for several days. An explanation based on the mol. structure of starch is advanced. J. J. Bikerman

Electrovoluminal effects in gels and sols of agar. M. S. Shul'man and A. M. Karel'shtadt. *Colloid J.* (U. S. S. R.) **5**, 741–8 (1939).—The viscosity of 0.5% soln. of agar is lowered by $BaCl_2$ more than by KCl; the effect is stronger in dialyzed than in electrodialyzed solns. It is concluded that electroviscous effect takes place and that the ions of the double layer are removed by electrodialysis. The swelling of agar is also inhibited by $BaCl_2$ more than by KCl. Similar results were obtained with agar fractions prepd. by extn. of an agar gel with water of various temps. J. J. Bikerman

Effect of sugars, alcohols, anions of organic acids, and of pH on the rigidity of agar gels. P. S. Zhelezkov. *Colloid J.* (U. S. S. R.) **5**, 733–40 (1939); cf. *C. A.* **33**, 6121[6].—The rigidity of 0.75% agar gels increases on addn. of p% of EtOH, glycerol, glucose or sucrose by $2p$%, $1.3p$%, $1.1p$% and $0.9p$%, resp. These substances also lower the reduction of the rigidity produced by heating agar to 75°. Acids increase the rigidity in the order Na citrate > Na tartrate > Na malate > Na acetate. In presence of citric acid the highest rigidity is observed at pH = 3.6; in these expts. the acid must be added immediately before gelation. J. J. Bikerman

Dielectric constant of the fractions of lyophilic colloids. I. Dielectric constant of the fractions of gelatin. S. M. Lipatov and M. S. Shul'man. *Colloid J.* (U. S. S. R.) **5**, 555–66 (1939).—The dielec. const. of "highly assocd." and of "thermolyzed" gelatin is the same and reaches in 3% gelatin soln. the value of 89 at 21–22°. Aging lowers the dielec. const. of the "assocd." but does not affect that of the "thermolyzed" gelatin. J. J. Bikerman

Effect of salts on the surface tensions of gelatin solutions. J. W. Belton. *Trans. Faraday Soc.* **35**, 1312–16 (1939).—The bubble-pressure method was used to det. the surface tensions at 25° of aq. solns. of gelatin to which NaCl, KCl, LiCl, KI or $BaCl_2$ was added at varying concns. of 1, 2, 3 or 4 *N*. A plot of surface tension *vs.* salt concn. shows a max. for NaCl, is almost horizontal for KCl, and increases almost linearly for both LiCl and KI. The surface tension of the stock soln. of gelatin remained const. over a period of several days and then began to fall gradually. These surface tensions were less than that of water, indicating pos. adsorption of gelatin at the surface. Victor R. Deitz

Determination of the coefficient of diffusion of electrolytes into gels using electrical conductivity. N. F. Ermolenko and S. A. Levina. *Colloid J.* (U. S. S. R.) **5**, 483–

91(1939).—The diffusion vessel used contained in its lower part 5 pairs of electrodes; the lower part was filled with gelatin, and the upper one with a KCl soln. The diffusion was calcd. from the increase of the cond. The coeff. of diffusion D is independent of the concn. of KCl between 0.1 and 1 N; it is 30% less than D in H_2O if the gel contains 5% of gelatin; in 20% gelatin it is 0.5 of the D in H_2O. J. J. Bikerman

Effect of hydrolysis of gelatin on periodic reactions. S. S. Kharamonenko. *Colloid J.* (U. S. S. R.) **5**, 755–9 (1939).—Periodical pptn. of $Ag_2Cr_2O_7$ (from $AgNO_3$ and $K_2Cr_2O_7$) was observed in gelatin boiled for 1, 2, 3, etc., hrs. The const. of periodicity and the size of $Ag_2Cr_2O_7$ crystals increase with the time of boiling. J. J. B.

Methods of obtaining periodic structures and determining periodicity constants. F. M. Shemyakin and P. F. Mikhalev. *Colloid J.* (U. S. S. R.) **5**, 655–8(1939).—Criticism of the technique used by Nikiforov and Runtso (*C. A.* **32**, 6928⁸). J. J. Bikerman

Anomalous dispersion as a method of studying colloidal solutions. A. V. Dumanskiĭ and M. S. Barvinok. *Colloid J.* (U. S. S. R.) **5**, 639–45(1939).—From published data on the abnormal dispersion of the dielec. const. of protein solns. the radii of protein mols. are calcd. by use of the dipole theory of Debye. It is found that the particle size of zein increases with rising temp., and that of egg albumin with dilu. J. J. Bikerman

Physical chemistry of the heat denaturation of proteins. I Interaction of denaturated and of native egg albumin with hydrogen and hydroxyl ions. A. P. Salchinkin. *Colloid J.* (U. S. S. R.) **5**, 467–73(1939).—The effect of albumin on the potential of a H electrode in HCl (0.008–0.1 N) and in dil. NaOH was observed. One g. of native albumin binds 0.0013, and 1 g. of albumin coagulated at 60° binds 0.0017 g. of H ions This difference indicates a chem. change in the course of denaturation.
J. J. Bikerman

Solubility of gases. I. The inert gases in water. D. D. Eley. *Trans. Faraday Soc.* **35**, 1281–93(1939).—To dissolve a gas mol. a cavity has first to be made in the solvent; second, the gas mol. is placed in this cavity liberating energy. This simple picture is found to hold for He, Ne, A, Kr and Xe dissolved in water. The neg. temp. coeff involved and its rapid increase to zero as the temp. is raised to 80° is explained mainly by the energy and entropy assocd. with the formation of the hole. These factors are calcd. thermodynamically and found to be zero at 0°, but increase strongly with increase in temp. The main factors for the inert gases are the loss of translational movement and entropy assocd. with cavity formation. Pos. temp. coeff. observed for some gases, N_2 and H_2, in water above 100° is explained by the large energy required to form a cavity at these temps., which outweighs the solute-solvent attraction. Victor R. Deitz

Solubility of barium iodate monohydrate in solutions of uni univalent electrolytes at 25°, and the calculation of the dissociation constant of iodic acid from solubility data. Solomon Naidich and John E. Ricci. *J. Am. Chem. Soc.* **61**, 3268–73(1939).—The solubilities were detd. in aq. solns. of KCl, HCl, KNO_3 and HNO_3. The data are used to calc. the ionization const. of iodic acid on the assumption of a const. mean activity coeff. for $Ba(IO_3)_2$ in either the acid or the K salt soln. of the same anion at the same total ionic strength. Corrections for the effect of undissocd. $BaIO_3^+$ were found to be negligible. The value of the thermodynamic const. K_a for iodic acid is found to be 0.163, in agreement with the best value (0.1686) derived from cond. data. A. B. Garrett

Solubilities of salts in dioxane-water solvents. T. W. Davis, J. E. Ricci and C. G. Souter. *J. Am. Chem. Soc.* **61**, 3274–84(1939).—The solubilities of Ag acetate, Ag sulfate and Ba iodate were detd. at 25° in a series of dioxane-water solns. extending from 0 to 100% dioxane. The solvent effect of KNO_3, $Ba(NO_3)_2$, $MgCl_2$ and $KBrO_3$ solns. on $Ba(IO_3)_2$ in water was detd. The solvent effects of KNO_3, $NaNO_3$, and $KClO_3$ on Ag acetate in 10% dioxane solns. and of $KClO_3$ on Ag acetate in 20% dioxane solns. were detd. The corresponding Debye-Hückel parameters are calcd. The Born equation fails to account for the course of the solubilities as the percentage of dioxane increases, predicting in each case lower solubilities than those observed. Modifications of the Born equation to agree with these observations are discussed.
A. B. Garrett

Solubilities of sodium and potassium salts of nitrophenols and related acids. O. C. Dermer and V. H. Dermer. *J. Am. Chem. Soc.* **61**, 3302–3(1939).—These soly. data, at 30°, were detd. in a search for a better precipitant for K. The data indicate that the most sensitive reagents of this group for K are dipicrylamine and dilituric acid. A. B. Garrett

The critical solution temperatures in aniline of the aromatic hydrocarbons and of paraffins of normal structures. M. D. Tilicheev. *Khim. Tverdogo Topliva* **9**, No. 2, 181–6 (1938); *Khim. Referat. Zhur.* **2**, No. 4, 47(1939).—The crit. soln. temp. in aniline of the high-mol. monoalkylbenzenes fits into one curve and permits interpolating the crit. temp. for the intermediate homologs of benzene. The crit. temp. for the dialkylbenzenes (diamyl- and diheptyl-benzene) are higher than for the monoalkylbenzenes of the same mol. wt. The normal-structure homologs of benzene have a slightly lower crit. temp. than the secondary alkylbenzenes. The critical temps. of the monoalkylnaphthalenes (heptylnaphthalene) are about 25° lower than those of the monoalkylbenzenes with the same no. of C atoms. For the normal-structure paraffin hydrocarbons from C_5H_{12} to $C_{32}H_{66}$ a regular increase in the crit. temp. of soln. in aniline is observed. These crit. soln. temps. fit into one curve, which permits a graphic interpolation of the points for the intermediate members of the series. The exptl. part of the article describes the synthesis and gives the consts. for diamyl- and diheptyl-benzene as well as for heptylnaphthalene. W. R. Henn

The solubility of a solid substance in a binary mixed solvent. I. E. I. Akhumov. *J. Gen. Chem.* (U. S. S. R.) **9**, 1207–19(1939).—A theoretical discussion of the ternary system S–L_1–L_2 and the deduction of the formula $Y = Y_1(1 - X)^{n_1} + Y_2X^{n_2}$ for the isothermic soly. of a solid substance S (under ordinary conditions) in a binary mixed solvent $L_1 + L_2$ in which Y_1 and Y_2 are the sep. solubilities of S in the binary systems S–L_1 and S–L_2, X is the no. of mols. of L_2 in the binary solvent. The exponents n_1 and n_2 det. the processes of solvation between the components of the mixed solvent L_1 and L_2 in the presence of the 3rd component S in the soln. With an increase of the temp. n_1 and n_2 decrease. The conditions for the mutual solvation of the components of the mixed solvent is more favorable in the regions of the pure solvents. An equation $K = [(Y_1 - Y)/Y_1 X] - 1$ is deduced which can be utilized for the calcn. of the no. of mols. of water that hydrate the alc. in water-alc. solns. If there are common ions between the S and L_1 or S and L_2, the partial soly. of the solid in the mixt. ($L_1 + L_2$) is expressed by $Y_1 = Y' + Y''$, where Y' is the decrease of the soly. caused by the mutual solvation of L' and L_2, and Y'' by ionic equil. Seven refereuces are given. **II.** *Ibid.* 1220–36(1939).—Examples illustrate the above deductions. The systems investigated were $C_{12}H_{22}O_{11}$–C_2H_5OH–H_2O, KCl–C_2H_5OH–H_2O, NaCl–C_2H_5OH–H_2O, Na_2SO_4–C_2H_5OH–H_2O, KCl–NH_3–H_2O, Na_2CO_3–NH_3–H_2O and $NaNO_3$–NH_3–H_2O. The equations given agree with the exptl. material on the soly. in ternary systems, and good agreement was found between $Y_{calc.}$ and Y_{exptl} The relation between the soly. of a solid substance in a binary solvent is true to the first approximation for n = const., and is exact for $n \neq$ const. The conceptions of partial soly. in a binary solvent are very important from a theoretical point of view. However, the question of the exptl. detn. of Y_1 and Y_2 when $Y_1 = 0$ and $Y_2 = 0$ is still not clear. Eight tables, 13 diagrams and 12 references. W. R. Henn

The solubility of high-molecular substances. VII. The thermodynamics of high-molecular solutions. G. V. Schulz. *Z. Elektrochem.* **45**, 652–8(1939); cf. *C. A.* **33**, 5265⁶.—At low concns. (c less than 0.1%) the solns. of high-mol. substances (mol. wt. from 50,000 to 443,000)

in acetone or toluene act as ideal dil. solns. With increasing concns. deviation from ideality results from the energy exchange between the 2 components of the soln. In the concn. range where osmotic measurements can be made the solns. are "regular." At higher concns. (about 1 1) the entropy term, $T\Delta S_i$, becomes negligible compared with the partial heat term. At still higher concns. the systems lose the properties of solns. and assumed those of compds. between the 2 components. L. E. Steiner

Capillary properties of α-amino acids. J. W. Belton. *Trans. Faraday Soc.* **35**, 1293 8(1939).—Surface tension of aq. solns. of glycine, alanine, α-aminobutyric acid and valine was detd. at 25°; also for these solns. with addn. of NaCl in varying amts. (1 to 4.4 moles per 1000 g. of water). The max. bubble pressure method was used (cf. *C. A.* **30**, 669[9]). The slope of the surface tension-concn curve varies with the length of the hydrocarbon chain, which situation becomes more marked in the presence of the NaCl. It is shown that with alanine the presence of salt changes the sign of the acid adsorption in the surface from neg. to pos. Victor R. Deitz

Change in the drop of potential at the air/solution interface as related to the age of the latter. A. I. Pankratov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 149 51(1939)(in English).—A study of the time variation of the potential drop at the interface air/soln., with a view to detg. the causes of the phenomenon, with application of the method of Guyot-Franklin, led to the following conclusions: In the absence of an accumulation of surface-active materials at the soln surface no change in the potential drop is noted. Otherwise the potential drop changes to more pos. values, the active surface materials penetrating to the surface mainly from the soln. and partly as a result of dust settling from the air. The effect of both factors produced, in 135 min., a change of 210 mv. in the potential drop of a *N* KBr soln. The effect of the 2nd factor alone produced a change of 35 mv. For a 0.01 *N* KCl soln. the change was 20 mv. The greater value for KBr is due to the more effective spreading of monolayers over the surface. 5 references. A. H. Krappe

The viscosities of solutions of sulfur dioxide in organic liquids. S. B. Cupp and H. E. Rogers. *J. Am. Chem Soc.* **61**, 3353-4(1939).—The viscosities and ds. of many solns. of SO_2 in Pr bromide, iso-Pr bromide, and Bu bromide were measured at 25°. An expansion in vol., on mixing, was found in each case. The results support the fact that when liquids show an expansion on mixing, the fluidity of the soln. is greater than the fluidity calcd. from the fluidities of the pure liquids. A. B. Garrett

The diffusion of hydrogen through iron at room temperature. J. H. de Boer and J. D. Fast. *Rec. trav. chim.* **58**, 984 93(1939)(in German).—Diffusion of H from buffer solns. will take place through Fe only when the pH of the buffer is less than 7 and the Fe is attacked with evolution of H gas The conclusion is that only H atoms diffuse and not H ions. It was also found that H atoms formed in H gas by an incandescent coil diffuse through Fe, whereas the mols. do not. This diffusion takes place against an atm. of H at any pressure. John E. Vance

A study of the diffusion processes by electrolysis with microelectrodes. H. A. Laitinen and I. M. Kolthoff. *J. Am. Chem. Soc.* **61**, 3344 9(1939); cf. *C. A.* **34**, 3085 —Current-time curves with various shapes of electrodes and diffusion fields in the electro-oxidation of ferrocyanide ions were detd. and the conditions under which theoretical diffusion conditions can be obtained are discussed. The temp. coeff. of the quantity $i\sqrt{t}$ was found to agree with the calcd. value and was const. to ±0.5% over a period of 20 min. when diffusion was linear and in such a direction as to produce a d. gradient in the downward direction. A. B. Garrett

Calculation of the properties of mixed solutions. A. B. Zdanovskiĭ. *Byull. Inst. Halurgii* **1938**, No. 4, 1-21; *Khim. Referat. Zhur.* **2**, No. 4, 30(1939).—A method of calcn. is proposed which is based on the additive properties of salt solns. obtained by mixing the isotonic soln. of the individual salts. It is necessary to know the p or the $\Delta p/p$ curves of the soln. contg. one salt. The necessary concns. x_1, x_2, x_3, x_4 of the isotonic soln. are found which satisfy the equation $(a_1/x_1) + (a_2/x_2) + (a_3/x_3) + (a_4/x_4) = 1$ where a_1, a_2, a_3 and a_4 are the concns. of the salts in the mixed soln. Formulas are given for the calcn. of the vapor pressure, sp. gr., coeff. of expansion, heat capacity, b. p., f. p. and η. The method of graphic calcn. is described. This method can be used for solving many theoretical as well as production problems and for the detn. of the accuracy of the exptl. data. The method was used for the detn. of the satn. point of the system Na_2SO_4 $Na_2SO_4.10H_2O$ astrakanite. W. R. Herzn

Application of the cage theory of liquids to the problem of ionic mobilities. J. J. Hermans. *Rec. trav. chim.* **58**, 917 27(1939)(in English); cf. Polissar, *C. A.* **33**, 1198[4].—The size of the cage is smaller for ions than for the solvent mols. because of the hydration layer. This size is such that classical and quantum mechanics are equally unsatisfactory. An expression independent of the cage size is therefore proposed for the frequency of oscillation of the ion in the cage. This expression is justified by the close agreement between calcd. and observed values of the temp. coeff. of ionic mobilities. The high mobility of the H ion is explained by its small size compared with the dimensions of the smallest possible cage. It is estd. that the potential barrier at the cage walls is such that any tunneling is negligible. John E. Vance

Transference numbers of ions in the system aluminum chloride-sodium chloride. Yu. V. Baĭmakov and V. I. Shelomov. *Trans. Leningrad Ind. Inst.* **1938**, No. 1, Sect. Met. No. 1, 36-48(in English, 49).—A review of the physicochem. properties of the system $AlCl_3$ NaCl is followed by a description of expts. on the detn. of the transference nos. in the system. For the range of 53–57 mol. % $AlCl_3$ and 47–43 mol. % NaCl the current is carried by the Na ions. During the transfer of current by the Na ions there is also some solvation of NaCl which is carried off to the cathode. Both Al and Cl are in a complex and, because of the small mobility, they do not act as carriers. B. Z. Kamich

An experiment for the determination of transference numbers by electromotive-force methods. Charles M Mason and Edward F. Mellon. *J. Chem. Education* **16**, 512-13(1939).—Two Ostwald H electrode assemblies and 2 Ag-AgCl electrodes are used to det. transference nos. with an error of about 0.48%. Wm. E. Trout, Jr.

Dependence of conductance on field strength. Darwin J. Mead and Raymond M. Fuoss. *J. Am. Chem. Soc.* **61**, 3589-90(1939); cf. *C. A.* **33**, 8087[4].—A correction is reported that brings the exptl. result in exact agreement with the theoretical value for the cond. of tetrabutylammonium picrate in Ph_2O at 50°. C. J. West

Properties of electrolytic solutions. XXI. The conductance of tributylammonium picrate in ethylene chloride at 25°. Darwin J. Mead with Raymond M. Fuoss and Charles A. Kraus. *J. Am. Chem. Soc.* **61**, 3257-9(1939), cf. *C. A.* **31**, 8320[6].—The concn. range covered was 1.8×10^{-4} *N* to 0.5 *N*. The equil. const. for the formation of triple ions is 0.045. The dissocn. const. of $NHBu_3$ picrate is 2.10×10^{-3} which gives a value of a (effective ion size) of 2.4 A. A. B. Garrett

Hydrolysis of stannous ion in stannous perchlorate solutions. Mel. Gorman. *J. Am. Chem. Soc.* **61**, 3342-4 (1939).—The extent of hydrolysis was detd. by the potentiometric measurements of the mean ion activity of total free $HClO_4$ with the aid of a H electrode and a normal calomel electrode. The data indicate that the hydrolysis follows the equation $Sn^{++} + H_2O = Sn(OH)^+ + H^+$. The value of the equil. const. for this reaction at 25° is 0.02. A. B. Garrett

The effect of certain salts on the lowest temperature at which a reaction between methane and oxygen is observed. W. P. Jorissen and H. O. Lebbink. *Rec. trav. chim.* **58**, 959-63(1939)(in English).—Explosive and nonexplosive mixts. of mine gas (70.0% methane) and O were passed through a heated tube coated with various salts. Formation of CO_2 was taken as an indication of reaction. The lowest temp. at which a reaction occurred

was 170° with a coating of LiF and the highest temp. was 540° with KI, while the uncoated tube gave a reaction at 250°. The temp. of observable reaction rose in the order Li, Na, K, Rb and similarly in the order F, Cl, Br, I.

Change in the rate of solution of copper during anodic and cathodic polarizations—difference effect—protective effect. N. D. Tomashov. *Compt. rend. acad. sci. U. R. S. S.* **24**, 152–5(1939)(in English).—A study of the kinetics of the soln. of Cu in 1 *N* and 0.1 *N* solns. of $NH_4S_2O_8$ and in 0.8 *N* soln. of $CuCl_2$ at room temp. of 18 20° by means of a gravimetric method led to the following conclusions: The rate of soln. increases with an increase in anodic polarization and decreases with an increase in cathodic polarization. The rate of soln. of Cu changes with the character of the current charge imposed. For Cu in solns. of 1 *N* and 0.1 *N* $NH_4S_2O_8$ the rate of soln. is decreased when anodic polarization and when cathodic polarization are imposed. For Cu in 0.8 *N* soln. of $CuCl_2$ the rate of soln. increases with anodic polarization and with cathodic polarization. The potential change of the Cu electrode as a result of cathodic polarization is much greater than during anodic polarization. 5 references. A. H. K.

Velocity of solution of sodium chloride and potassium chloride crystals at different temperatures. A. B. Zdanovskiĭ *Bull. Inst. Hidurgii* **1938**, No. 6, 22–31; *Khim. Referat. Zhur.* **2**, No. 4, 30(1939).—The velocity of soln. of NaCl and KCl at different temps. was studied. A method was developed for a running solvent with a freely suspended state of the crystals. The method increased the accuracy of the detns. 5–10 times. The calcn. of the velocity const. was made from the formula of Noyes which was modified to the following form $K = A(\sqrt[3]{M_0} - \sqrt[3]{M})/t(C_s - C)$ after the changes of the size of the crystal surfaces during soln. were taken into consideration. In this equation M_0 and M are the wts. of the crystals at the beginning and at the end of the expt., C is the vol. concn. of the satn. soln., C_s the concn. at the moment T, $A = d/2$ and d is the d. of the crystals. The values obtained were several times greater than those given in the literature. The temp. dependence of the velocity consts. is expressed by curves that are slightly curved toward the temp. axis. Calcns. were made from the formulas $K = A\sqrt{T}e^{-Q/RT}$, $K = Ae^{-Q/RT}$ and $K(C - C_s) = 173.7$ $(C = 211.5/T$ was obtained from the exptl. $K_{275°K.}$ and $K_{360°K.})$. The smallest deviation (10%) from the exptl. values was found at $K_{325°K.}$ by using the formula $K(C - C_s)_0 = 175.7$.
W. R. Henn

The hydrolysis of bromine. The hydration of the halogens. The mechanism of certain halogen reactions. Herman A. Liebhafsky. *J. Am. Chem. Soc.* **61**, 3513–19 (1939). Corrections are made in earlier work (cf. *C. A.* **28**, 5318[2]) on the hydrolysis of Br. These corrections strengthen the case for the hypothesis that the anomalous temp. coeffs. assocd. with aq. halogen solns. result from shifts in the hydration equilibria. The heats of hydration for the halogens are calcd. from these equilibria data and are found to compare favorably with those calcd. from kinetic data which involve the specific rates at which H_2O_2 is oxidized by each of the 3 halogens. This problem is also approached by data on the reaction of H_3AsO_3 with I_2 and by spectrophotometric measurements of solns. of I_2 in CCl_4 (in which there are no definite hydrates) and solns. of I in water. The latter differ from the CCl_4-I_2 solns. in 3 spectrophotometrically measurable ways which are suggested to be due to the formation of definite I-solvent compds.
A. B. Garrett

Hydrolysis of benzoic and related esters in varying media. R. A. Harman. *Trans. Faraday Soc.* **35**, 1336–43 (1939).—The alk. (NaOH) hydrolysis of esters of the types $XC_6H_4CH_2COOEt$ and $XC_6H_4CH{=}CHCOOEt$ was studied from −20° to 40°; X was H, *p*-NO_2 or *p*-NH_2. The reactions were followed by adding excess acid to a measured sample and back-titrating with cresol red as indicator. The consts. of the Arrhenius equation, $k = PZe^{-E/RT}$, were detd. The solvent effects on benzoic and on *m*-nitrobenzoic ester hydrolysis were also studied in acetone-water mixts. As the solvent compn. was altered, the correlation of log PZ with E, previously reported by Timm (cf. *C. A.* **32**, 7331[6]), was found. The effect on E produced by the substituent varied with solvent compn.
Victor R. Deitz

Kinetic studies on iodine derivatives. I. The thermal decomposition of acetyl iodide. J. Leslie Jones. *J. Am. Chem. Soc.* **61**, 3284–8(1939).—The main products of the reaction, in the temp. range 290–340° were identified as CO, CH_4, I_2 and polymerized ketene. The decompn. is unimol. with respect to Ac iodide and the rate consts. depend upon the initial pressure of iodide. The data indicate a chain mechanism which is broken by the walls of the vessel. The value of the activation energy, E, is 43,100 cals./mole. The data indicate that the radical CH_3COI may be an intermediate rather than the radical CH_3CO.
A. B. Garrett

The critical increment of ionic reactions. IV. The influence of dielectric constant and ionic strength. Louis Rampino and W. J. Svirbely. *J. Am. Chem. Soc.* **61**, 3534–7(1939); cf. *C. A.* **32**, 6932[8].—The rate of conversion of NH_4 cyanate to urea was studied over the temp. range 30 to 60° in isodielec. mixts. of iso-PrOH with water over the dielec. range of 63.5 to 20. The effect of ionic strength on the observed crit. increments at zero ionic strength agrees well with equations previously derived (cf. *C. A.* **32**, 6932[8]). The crit. increment is apparently independent of the dielec. const. in isodielec. mixts. over the major portion of the range investigated. The value of the collision factor Z in the Arrhenius theory varies with dielec. const. The collision theory is in satisfactory agreement with the thermodynamic treatment at the higher dielectrics used. **V. The influence of dielectric constant and ionic strength.** W. J. Svirbely and James Lander. *Ibid.* 3538–42.—The rate of conversion of NH_4 cyanate to urea was studied over the temp. range 30 to 60° in isodielec. mixts. of dioxane with water over a dielec. range 63.5 to 5. The effect of ionic strength upon the observed crit. increments at zero ionic strength agrees well with the theory. The effect of the dielec. const. on the rate consts. is in reasonably good agreement with the Scatchard-Christiansen theory (cf. *C. A.* **24**, 2365) at the higher dielec. consts.
A. B. Garrett

Decomposition of acetaldehyde and deuterioacetaldehyde. R. E. Smith. *Trans. Faraday Soc.* **35**, 1328–36 (1939).—The reactions of acetaldehyde and the completely substituted deuterioacetaldehyde (99.5%) were compared. The gas was caused to react in a silica bulb of about 200 cc. contained in an elec. furnace between 500 and 570°; the reactions were followed manometrically. The pressures ranged from 25 mm. to 450 mm. In all cases the light and heavy compds. gave similar results; the pressure increased to a max. of 97% over the initial pressure. The effects of the addn. of (1) ethylene, (2) ethane or (3) CO_2 were studied. (1) and (2) had no effect within the error of the expts.; (3) gave a slight increase in the velocity of the decompn. The effects of the products on the reaction velocity were small. Activation energies for both aldehydes are given.
Victor R. Deitz

Kinetics of polyesterification: A study of the effects of molecular weight and viscosity on reaction rate. Paul J. Flory. *J. Am. Chem. Soc.* **61**, 3334–40(1939).—The kinetics of 2 polyesterifications, diethylene glycol-adipic acid and decamethylene glycol-adipic acid, are compared with several nonpolymer-forming esterifications, diethylene glycol-caproic acid, lauryl alc.-adipic acid, and lauryl alc.-lauric acid. Preliminary exptl. data on the reaction of diethylene glycol with adipic acid catalyzed by *p*-toluenesulfonic acid are presented. In the absence of a catalyst the course of the reaction corresponds to a continuous increase in kinetic order, becoming approx. 3rd order at large extents of reaction. The fact that polyesterification and esterification follow similar courses indicates that the reaction rate is not affected by either increase in mol. wt. or the concurrent increase in viscosity. This conclusion agrees with theory (*C. A.* **30**, 7941[8]).
A. B. Garrett

Rates of the thermal reduction of dichromic acid by quinine, hydroquinine and cinchonine in dilute sulfuric

acid at 0° to 60°. Lawrence J. Heidt. *J. Am. Chem. Soc.* **61**, 3455-8(1939).—The thermal rates of oxidation of quinine, hydroquinine and cinchonine by dichromic acid in 1.55 *M* H_2SO_4 are the same within 5%. The reactions are autocatalytic. The initial rates are given by the equations: $-\Delta(K_2Cr_2O_7)/\Delta t = k(K_2Cr_2O_7)$ (alkaloid)$^{1/2}$ and $\log_{10}k = 4.05 - 2000/T$. Light absorbed by the alkaloids initiates a different reaction which is affected very little by thermal energy. A. B. Garrett 1

Catalyzed polymerization of butadiene at a liquid-gas interface. G. Gee, C. B. Davies and H. W. Melville. *Trans. Faraday Soc.* **35**, 1298-1312(1939).- An app. was devised in which a const. pressure of butadiene up to several atms. could be maintained above a water surface, the surface tension of which (detd. at intervals by the ring method) served to follow the course of the polymerization. The reaction rate was detd. as a function of the concn. and stability of the H_2O_2 catalyst, the pressure of the butadiene and the temp. (50° to 80°). The stability of the H_2O_2 soln. was varied by adjusting the concn. of the added H_2SO_4 from 0 to 10^{-2} *N*, the percentage of H_2O_2 decompd. in 18 hrs. dropping from 100 to 21.9. Hence the lifetime of the active polymer is shorter than that of the time of the reaction. From a study of the kinetics it is shown that the mechanism of the reaction consists in the reaction of a mol. of H_2O_2 with 1 monomeric mol. This complex polymerizes and is terminated by some deactivating collision of the monomer of a kind different from that for its propagation. Victor R. Deitz 2 3 4

Study of the isomerization of butanes and their equilibrium ratios. B. L. Moldavskiĭ and T. V. Nizovkina. *Compt. rend. acad. sci. U. R. S. S.* **23**, 919-20(1939)(in English).—The catalytic isomerization of butane to isobutane and *vice versa* by $AlCl_3$ was studied and the equil. compn. of the mixt. butane-isobutane was detd. in the temp. range 70 to 180°. The expts. were made at 70° in the liquid phase (by shaking the butanes with $AlCl_3$ + $CuSO_4.2HCl$ in a sealed ampoule in a water thermostat) and at 110-180° in the vapor phase (by passing the butane vapors together with HCl over $AlCl_3$). The amts. of isobutane in the equil. mixts. were found at 70°, 110°, 130°, 150° and 180° to be 79%, 72%, 67%, 63% and 58%, resp., the results obtained at 70° (liquid phase) being calcd. for the vapor phase according to Raoult's law. The relation between the equil. const. K_p and the temp. is expressed by the equation: $\log K_p = 611/T - 1.204$. The data of previous investigators on butane isomerization are discussed. Dora Stern 5 6

The equilibrium and kinetics of the thermal isomerization of dichloroethylene catalyzed by iodine. Reuben E. Wood and Roscoe G. Dickinson. *J. Am. Chem. Soc.* **61**, 3259-63(1939).- Equilibria between the cis and trans isomers of dichloroethylene were established and measured in the pure liquids and in their solns. of benzene, cyclohexane and decahydronaphthalene with I as a catalyst. A method of analysis based on dielec. const. measurement was employed to det. the extent of isomerization. Neither the activation energies nor the actual rates vary much from one medium to another. The activation energy is in the order of 30,000 cals. The kinetics are compatible with an I-atom catalysis. Evidence against an ionic catalysis is presented. A. B. Garrett 7 8

Catalytic oxidation of ammonia at low pressures on platinum and on alloys of platinum with rhodium and ruthenium. Walther Krauss and Hans Schuleit. *Z. physik. Chem.* **B45**, 1-18(1939); cf. *C. A.* **32**, 4865[4].—Mixts. of NH_3 and O_2 (1:1) were passed over the catalysts at 1250° at a rate of 1.545 micromol. per hr. and a pressure of 0.03 mm. The catalysts were Pt contg. 1, 5 or 10% Rh (I) and Pt contg. 1% Rh and 2% Ru (II) and pure Pt (III). The reaction $NH_2OH + O_2 = HNO_3 + H_2O$ takes place on the catalysts. The source of N_2 is the reaction $HNO_2 + NH_3 = N_2 + 2H_2O$. For II and III an induction period was found, during which the yield of NH_2OH and HNO_3 depends on the time of contact with the catalyst. The direction of the curve is opposite for the 2 catalysts. No induction period was detected for I. G. M. Murphy 9

The catalytic interaction of acetylene and hydrogen on platinum. A. Farkas and L. Farkas. *J. Am. Chem. Soc.* **61**, 3396-3401(1939); cf. *C. A.* **33**, 6128[3].—The catalytic hydrogenation of C_2H_2 was investigated at pressures of 70-150 mm. in the temp. range of 20-140° on a Pt catalyst. The rate of hydrogenation increases with increasing H_2 pressure but is strongly reduced with increased C_2H_2 pressure. The presence of C_2H_2 retards the rate of ortho-para conversion of H_2. The ratio of the rate of hydrogenation by H_2 to that of D_2 is 1.5 at 20°. The hydrogenation of C_2H_2 proceeds in 2 distinct stages: first, all the C_2H_2 is reduced to C_2H_4 then the C_2H_4 is hydrogenated to C_2H_6. The start of this second step is indicated by a sudden increase in the rate of hydrogenation. The results indicate that C_2H_2 is strongly adsorbed on the surface of the catalyst and that C_2H_2 can displace both H_2 and C_2H_4 in the adsorption layer. The mechanisms of hydrogenation and exchange reactions are discussed. A. B. Garrett

The change in heat of activation of the mixed phase, Au-Cu, at the transition order ⇌ disorder. Armin Schneider. *Z. Elektrochem.* **45**, 727-31(1939).—The change in the heat of activation of the decompn. of HCOOH vapor by a Au-Cu alloy, contg. 50 at. % of Au as catalyst was used to study the different states of the alloy. When the quenched solid soln. alloy was annealed at temps. between 200 and 500° it passed through 2 metastable characteristic intermediate states, one at 250-300° during transition to the ordered state at 350°, and the other at 385-415° on passing to the unordered lattice at the higher temps. These intermediate states showed about 8 and 5 kg.-cal. higher activation energies, resp., than did the stable ordered or unordered states. L. E. Steiner

The freezing point of rhodium. C. R. Barber and F. H. Schofield. *Proc. Roy. Soc.* (London) **A173**, 117-25(1939). - The f. p. of Rh, 1966 ± 3°, was detd. in a vacuum by measuring the ratio of brightness for a black body held at the f. ps. of Rh and Au. The method of measurements Natl. Bureau of Standards) is described. A total of 95 melts on 2 ingots was observed. 4 references. J. N. L.

Dilatometric study of the system iron-nitrogen. V. I. Prosvirin and G. I. Alekseeva. *Vestnik Metalloprom.* **11**, No. 1, 72-7(1939).—The investigation was conducted with a Shevenar dilatometer and was limited to Fe specimens contg. 1, 1.3, and 3.06% N. The N was introduced into the specimens by nitriding in a quartz tube. On the basis of the dilatometric curves the changes in the coeff. of expansion were plotted. B. Z. Kamich

The α solubility limit and the first intermediary phase in the copper-silicon system. A. G. H. Andersen. *Trans. Am. Inst. Mining Met. Engrs., Inst. Metals Div., Tech. Pub.* No. **1126**, 17 pp.(1939).—An investigation of the binary Cu-Si system below 7% Si is reported. Both x-ray methods and microscopic technique were employed. *An appendix* to the paper, giving chem. and spectrographic analyses, tables and description of app., can be obtained, from *Am. Doc. Inst., Doc.* 1256 (Microfilm 50¢, photoprint $3.20). C. L. Mantell

The transition-point diagram of the zirconium-titanium system. J. D. Fast. *Rec. trav. chim.* **58**, 973-83(1939)(in English).—Ti and Zr are isomorphous at nearly all temps. in both their hexagonal and body-centered cubic (high temp.) forms. By means of resistance measurements it was found that the solid solns. have a transition-point min. at 545° when the at. ratio is 1:1. The transition temp. of pure Ti was redetd. as 885° ± 10°. The m.-p. diagram of the system also shows a min. at about 1575° with an at. ratio Ti:Zr = 2:1. John E. Vance

Determination of the composition diagram for the liquid-gas system methane nitrogen hydrogen. F. A. Shtekkel and N. M. Tsin. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 8, 24-8(1939).—Data are presented and diagrams given for the systems N_2-H_2, CH_4-H_2 and N_2-H_2-CH_4 at 107.7°K. at 10-100 atm. The results can be used in calcns. for the *fractionation of coke gas.* H. M. Leicester

Equilibria in systems with salting out. R. V. Mertslin. *J. Gen. Chem.* (U. S. S. R.) **9**, 1303-9(1939).—Different variants of diagrams with salting out were studied theoretically with the principle of prevalence used as a basis for

the investigation. They are different cases of the crystn. of ternary systems with one binary sepn. into layers. Neither the inorg. nor the org. salts can be regarded as specific substances responsible for a given phenomenon. Salting out takes place in systems in which the prevalent role belongs to the binary system which is formed by a solid component (the salting-out substance) with one of the components of the salting-out system. Ten diagrams and 4 references are given. W. R. Henn

The reciprocal system $Ba(SH)_2 + 2NaCl = BaCl_2 + 2NaSH$. D. V. Bezuglyĭ and F. M. Kutsakov. *J. Chem. Ind.* (U. S. S. R.) **16**, No. 8, 37–40(1939).—NaHS is best prepd. by passing H_2S into NaOH soln. until phenolphthalein gives no color, then evapg. the soln. in a vacuum at 60–80° and allowing it to stand for 2–3 days at room temp. for crystn. The NaHS is very hygroscopic. Its soly. at 20° is 42%. $Ba(SH)_2$ is obtained by salting out from its soln. with NaHS, or, in smaller yield, by pptg. with EtOH. At 20° the equil. system NaHS–NaCl–H_2O contains 35.8% NaHS and 2.06% NaCl; the system NaHS–$Ba(HS)_2$–H_2O contains 40.85% NaHS and 0.15% $Ba(HS)_2$ and the system $Ba(SH)_2$–$BaCl_2$–H_2O contains 22.3% $Ba(SH)_2$ and 14.0% $BaCl_2$. The phase-rule diagram at 20° for the reciprocal system of all the salts is constructed and used to derive conditions for pptg. $BaCl_2$ from the mixt. To get max. pptn. of $BaCl_2$ the initial soln. must contain 35% $Ba(SH)_2$. This concn. can be obtained only by satg. a soln. contg. 17.9% $Ba(SH)_2$ and 11% BaS with H_2S. H_2S can be obtained by treating $NaHCO_3$ with NaSH, and the Na_2CO_3 also formed in this reaction can be used to ppt. $BaCO_3$ from the $BaCl_2$ mother liquors. The process gives 340 kg. $BaCl_2$ and 360 kg. $BaCO_3$ per ton of barytes used. H. M. Leicester

Simplified formulas for calculating the coefficients of heat transfer and Reynolds number. I. A. Gorlovskiĭ. *Trudy Moskovskogo Mashinostroenie* **8**, No. 6, 21–5(1939).—Simplified formulas are derived for calcg. the coeffs. of heat transfer and Reynolds no. for heating of liquids under laminar flow. The application of the formulas is illustrated for 13 compds. including EtOH, MeOH, acetone, H_2O, C_6H_6, and heptane. B. Z. Kamich

Measurement of specific heats of gases at high temperatures. Aurel D. Potop. *Pub. sci. tech. ministère air* (France), No. **148**, 54 pp.(1939); cf. *C. A.* **32**, 1173[8]; **33**, 9111[1].—Means of circumventing the exptl. difficulties in the method of Blackett, *et al.* (*C. A.* **24**, 2369) are described. This method may be extended to studies in the natural convection of air, and to measure the thermal conduction of metals. John W. Knowlton

The specific heat of gases at high temperatures. R. W. Fenning and A. C. Whiffin. *Trans. Roy. Soc.* (London) **A238**, 149–212(1939).—The explosion method was employed in the measurements; an app. that is fully described was used. Direct measurement of the heat loss to the vessel walls was avoided. The explosion vessel consists of a hollow steel sphere made up in halves that are clamped together by means of a flanged joint. A manometer is connected to the lower half, and a gunmetal casing surrounds the vessel. The intervening space is supplied with steam. The calibration of the manometer, detn. of mixt. compn. and technique for the addn. of H_2O vapor to certain gas mixts. are described in detail. The investigation covered CO, N_2, CO_2, H_2 and H_2O. Values for the molal heat capacities are represented graphically and by equations. The results are in fairly close agreement with the values deduced from spectroscopic data. **The experimental determination of the compressibility of gases.** *Ibid.* 213–28(supplement).—In the above investigation, compressibility data were required on gas mixts. at medium pressures. The method is fully described. A known vol. is charged with the gas or mixt. This is then expanded to atm. pressure, and the vol. measured. The method is capable of high precision provided there are available sensitive measurements of temp. and pressure. J. W. K.

Thermal measurements on very pure sulfur dioxide. L. Riedel. *Bull. Intern. Inst. Refrig.* **20**, No. 4, Annex No. **5**, B1-10(1939).—The vapor pressure from −60° to 15°, equation of state of the gas, heat of vaporization from −20° to 15°, and sp. heat of the liquid from −40° to 0° were detd. The sp. heat in the vapor state was calcd. The vapor pressure is representable by the relation $\log p(\text{mm. Hg}) = 43.885_{22} - 2378.72/T - 14.11350 \log T + 0.0083319T$. The P-V-T relation of the gas was detd. from 5° to 50°, and the deviation from ideality (B in $V = RT/(p - B)$) was evaluated as $123.5/(T/100)^{2.7}$ cc./g. John W. Knowlton

The specific heat of a monatomic liquid. Wm. J. Archibald. *Phys. Rev.* **56**, 926–32(1939).—The partition function for an atom in a monatomic liquid is evaluated by assuming that the atom is constrained by its nearest neighbors to move in a spherical region, and that the potential energy of the atom at any point within this region can be found if the law of force between the 2 atoms is known. On the basis of this partition function an expression for C_v is derived, and the theory is checked by a comparison of the exptl. and theoretical values of C_v for liquid A. Bernard Lewis

Vapor-pressure measurements from new dynamic and static methods. The applicability of the reaction isochore to the measurement of the latent heat of vaporization. Dan Rădulescu and Maria Alexa. *Bul. Soc. Chim. Romania* **20A**, 89–113(1938)(in German).—The following vapor pressures (in mm. Hg) were measured with dynamic, *d*, and static, *s*, methods.

Additional values for $CHBr_3$ are 0.29, 0.41, 0.55, 0.65, 0.75, 0.90, 1.13, 1.34, 1 44, 1.54, 1.60, 1.73, 1.81 and 1.89 mm., resp., for the temps. −14, −13 .... to −1°. Addnl. values for benzene are 28.42, 32.40 and 36.35 for the temps., 2, 4 and 6°, 50.24 and 55.11 for the temps., 12 and 14°, 68.35, 82.65 and 90.99 for the temps., 18, 22

and 24°, resp. With $CHBr_3$ and $C_2H_4Br_2$ a glycerol manometer was required because these substances react slowly with Hg to give high apparent pressures. L. E. S.

The specific heats of tantalum in the normal and in the superconducting state. W. H. Keesom and M. Désirant. *Proc. Acad. Sci. Amsterdam* **42**, 536-7(1939).—In the absence of a magnetic field, the sample of Ta investigated showed a discontinuity in the sp. heat at 4.075°K. At this temp., the difference in sp. heat between the superconducting state and the normal condition is 0.00881 cal./degree mol. Measurements made in a magnetic field gave much lower values than those calcd. It was observed that the *H-T* curve which indicates the temp. at which the induction penetrates into the metal is different from the curve indicating the temp. at which elec. resistance reappears. It is not evident that the former curve is that which characterizes the difference between the superconducting and the normal condition. John W. Knowlton

The specific heat of some ethylene halides. Wilford E. Railing. *J. Am. Chem. Soc.* **61**, 3349-53(1939).—The heat capacities of 1,2-dibromoethane, 1,2-dichloroethane, and 1,2-bromochloroethane were measured over the range 90-320°K. The heats of fusion and transition were measured also. The questions of restricted intramol. rotation and cis-trans equilibria are discussed with reference to their effect upon the specific heat of these compds. A. B. Garrett

The heats of formation and the states of order in the system gold-copper. Friedrich Weibke and Udo Freiherr Quadt *Z. Elektrochem* 45, 715-27(1939).—The e. m.f. of Au-Cu alloys against a Cu electrode at temps. between 320 and 550° were obtained in evacuated cells with a eutectic mixt. of LiCl-KCl or of LiCl-RbCl, and small amts. of pure CuCl, as electrolyte. At temps. above about 425° the Au and Cu atoms are distributed statistically in the crystal lattice. At lower temps. the existence of the phase, Au_2Cu_3, is established in addn. to the phases, AuCu and $AuCu_3$. From the Gibbs-Helmholtz relation the heats of formation of the solid solns. from the solid metals at 500° are calcd. and are found to have a max. value of 1.25 kg.-cal. per g. atom of alloy at about 55 at. % Cu. The heats of transition from the unordered solid soln. to the ordered phases, AuCu, Au_2Cu_3 and $AuCu_3$ are, resp., 0.38, 0.14 and 0.37 kg.-cal. per g. atom of alloy. L. E. Steiner

The high-temperature calorimetry of alloys. O. Kubaschewski and Alexander Walter. *Z. Elektrochem.* **45**, 732-40(1939); cf. *C. A.* **31**, 8478[9]; **32**, 6600[5]; **34**, 3[9].—The heats of formation, at temps. from 600 to 650°, over wide concn. ranges were obtained for the systems, Ca-Bi, Ca-Sb, Ca-Tl, Ca-Pb, Mg-Sb and Mg-Sn. L. E. S.

Thermal data on organic compounds. XIX. Modern combustion data for some nonvolatile compounds containing carbon, hydrogen and oxygen. J. Wilfred Richardson and Geo. S. Parks. *J. Am. Chem. Soc.* **61**, 3543-6(1939).—The heats of combustion were detd. for the following substances at 25° and const. vol.: β-methylnaphthalene, phthalic anhydride, phthalic acid, anthracene, phenanthrene, stilbene, pyrene, hexadecane, cetyl alc., triphenylbenzene and polyisobutylene. From these data the corresponding heats of combustion and heats of formation at const. pressure are calcd. A. B. Garrett

Self-consistent field with exchange for carbon. A. Jucys. *Proc. Roy. Soc.* (London) **A173**, 59-67(1939); cf. *C. A.* **29**, 33[9]; **32**, 4073[7].—Calcns. were made for the normal states of C^{++}, C^{4+} and for the ^3P, ^1D and ^1S states of neutral C. For the latter, energies were also

obtained for the $2s^22p^3$ shell both with and without inclusion of the excited $2p^4$ configuration superimposed on the normal state. G. M. Murphy

The action of helium on polonium under the influence of electric discharge. Rafael Mendez. *Anales asoc. quím. argentina* **27**, 130–9(1939).—Helium, at a pressure of 3.8 mm. and under the influence of elec. discharge, combines with Po, forming an ionizing compd. Rise of temp. favors the reaction. Even at 100°, the Po begins to vaporize at low pressures and the activated He acts upon such vapors. E. M. Symmes

Diffusion of ions in a discharge and the initial rate of gas deionization. I. V. L. Granovskiĭ. *Compt. rend. acad. sci. U. R. S. S.* **23**, 883–7(1939)(in English); cf. *C. A.* **33**, 6703[3].—The diffusion theory is used to calc. the ambipolar diffusion coeff. D_a and μ, the root of the equation $nw/n_0 = J_0(\mu)$, where nw/n_0 is the ratio of the ion concn. at the wall to that at the axis and J_0 is Bessel's function of zero order. D_a is calcd. for 2 limiting cases (1) direct ionization and (2) cumulative ionization. The theoretical and exptl. values of μ obtained from probe measurements in a Hg vapor discharge tube are found to agree. II. *Ibid.* 888–90.—The deionization (time const.) can be calcd. from the relation $\tau = R^2/D_a\mu^2$. On the assumption D_a at the start of deionization has the steady discharge value, the initial value (τ_0) can be calcd. These calcns. are compared with those detd. by probe measurements with a cathode oscillograph. The results are (1) for pR less than 0.2 mm. Hg the calcd. values are in agreement with expt., (2) with tubes of large diam. the best agreement occurs when D_a is calcd. on the basis of accumulative ionization, (3) for smaller tubes the value of τ_0 is intermediate between those calcd. from the 2 assumptions on D_a and (4) in case of pR more than 0.25 cm. Hg, the initial disintegration rate is greater than the calcd. value with either of the assumptions. Earl A. Gulbransen

A preliminary report on the polarization of electrons. Kozi Kikuti. *Proc. Phys.-Math. Soc. Japan* **21**, 524–7(1939)(in English).—The asymmetry of the distribution of fast electrons after double right-angle scattering from Au foils was found to be in good agreement with the predictions of Mott (*C. A.* **26**, 4750). A. O. Allen

Origin of the spotted regions of electron-diffraction patterns of etched crystals. G. Menzer. *Ann. Physik* **36**, 239–48(1939).—These regions are due only to the mosaic structure of the diffracting crystal layers, as shown by results obtained with a Cu crystal. S. L. Gerhard

Intensities of electron-diffraction rings. M. Blackman. *Proc. Roy. Soc.* (London) **A173**, 68–82(1939).—The dynamical theory of Bethe (*C. A.* **23**, 332) is applied to electron diffraction from thin films. A criterion is presented for detn. of the conditions under which the kinematical theory of Laue is applicable. With the thin films and fast electrons commonly used experimentally, the latter theory is not usable. An approx. intensity formula is derived and is applied to exptl. data on Cu and Ag films; good agreement is obtained with a reasonable assumption for the av. crystal size. G. M. Murphy

Internal absorption of γ-rays in radium-beryllium neutron sources. Leon F. Curtiss. *J. Research Natl. Bur. Standards* **23**, 617–19(1939)(Research Paper No. 1257).—The internal absorption of γ-rays in Ra-Be neutron sources has been detd. for a source contained in a brass cylinder of 8 mm. internal diam. and 24.5 mm. internal length with walls 1 mm. thick. The cylinder contained a mixt. of 1.237 mg. of finely powd. Be and Ra sulfate contg. 139.7 mg. of Ra element. From measurements made in the usual way with a γ-ray electroscope with 1 cm. of lead filtering, the absorption correction was found to be 5.1%. These results can be used to det. the actual Ra content for such sources within the usual limits of error, that is, ±0.5%. Robert M. Simha

Energy of conversion electrons arising in the transformation of bromine isomers. L. I. Rusinov and A. A. Yuzefovich. *Compt. rend. acad. sci. U. R. S. S.* **24**, 129–30(1939)(in English).—The energy of the conversion electrons produced in the transformation of isomeric Br nuclei was detd. by means of a magnetic spectrograph (diagram included). The energies of conversion on the *K* and *L* levels are 33.5 ± 2 and 46.5 ± 3 e. kv., resp. T. H. Dunkelberger

β-spectra of iodine. G. F. Tape. *Phys. Rev.* **56**, 965–71(1939).—Bombardment of Te and I with deuterons and neutrons resulted in radioactive I. The momentum distributions of the β-particles were examd. in a cloud chamber placed in a uniform magnetic field and filled with H. Energies of the γ-radiation were detd. from the electrons ejected from Pb within the cloud chamber. The probable isotopes, half-lives and energies of β- and γ-radiation, resp., are: I^{126}, 13.0 ± 0.3 days, 1.20 ± 0.03 m. e. v., γ-radiation detected but could not be measured; I^{128}, 25 ± 1 min., 2.40 ± 0.07 m. e. v., as for I^{126}; I^{130}, 12.5 ± 0.5 hrs., 0.83 ± 0.03 m. e. v., 0.59 m. e. v.; I^{131}, 8.2 ± 0.3 days, 0.687 ± 0.010 m. e. v., 0.27 and 0.46 m. e. v. G. M. Murphy

β-spectrum of actinium K. M. Perey and M. Lecoin. *J. phys. radium* **10**, 439–40(1939).—See *C. A.* **33**, 9128[9]. H. Game

Disintegration of uranium by neutrons. N. A. Perfilov. *Compt. rend. acad. sci. U. R. S. S.* **23**, 896–8(1939)(in French).—Cloud-chamber expts. are performed on the disintegration of U_3O_8 by neutrons (Rn + Re) of 1000 millicuries intensity. A preliminary analysis of 1000 stereophotographs indicates (1) the U nucleus is disintegrated into heavy particles, (2) some of the heavy particles have 6 times the ionization power of an α-particle and (3) the max. path for the nuclei of recoil is 3 cm. (air). Earl A. Gulbransen

Determination of radium in powerfully emanating preparations by measuring the emanation "in statu nascendi." Alexander Janitzky. *Kolloid-Z.* **89**, 316–19(1939).—A stream of air is bubbled at a const. rate through or over the Ra-contg. prepn. into an evacuated ionization chamber. After about 25 min., a steady state is reached in which emanation is carried over as fast as formed, and from a measurement of the amt. of emanation carried in a given time, the amt. of Ra present is readily calcd. The method is less time-consuming and nearly as accurate as the older methods. A. O. Allen

The radioactive determination of protactinium in siliceous terrestrial and meteoritic material. Walter C. Schumb, Robley D. Evans and Jane L. Hastings. *J. Am. Chem. Soc.* **61**, 3451–5(1939).—Conclusion: Within the limits of error the age of the U atoms in the specimen of the Pultusk meteorite is the same as for the terrestrial U. A. B. Garrett

The Scherrer formula for x-ray particle-size determination. A. L. Patterson. *Phys. Rev.* **56**, 978–82(1939).—It is suggested that the calcn. for the ellipsoidal particle based on the tangent plane approximation will provide a satisfactory basis for future work. S. L. Gerhard

The influence of temperature on x-ray interference in monatomic hexagonal crystals. Max Kohler. *Ann. Physik* **36**, 227–38(1939).—The temp. factor depends on the angle between the normal to the reflecting plane and the hexagonal axis. S. L. Gerhard

Indirect excitation in x-ray interference. Ernst Lamla. *Ann. Physik* **36**, 194–208(1939).—Math. S. L. G.

The diffraction of x-rays by small crystalline particles. A. L. Patterson. *Phys. Rev.* **56**, 972–7(1939).—The approx. shape of a particle can be obtained from accurate x-ray measurements. S. L. Gerhard

Isotope shift in the boron spectrum. W. Opechowski and D. A. de Vries. *Physica* **6**, 913–17(1939)(in English).—The calcd. sp. isotope shift is −0.33 cm.$^{-1}$ (cf. *C. A.* **24**, 5620) for the $3\ ^2S_{1/2} - 2\ ^2P_{1/2, 3/2}$ transition in neutral B at 2497–8 A. The exptl. value is −0.37 cm.$^{-1}$ (cf. *C. A.* **33**, 6715[8]). G. M. Murphy

Compilations of spectroscopic data. George R. Harrison. *J. Applied Phys.* **10**, 760–7(1939).—References and brief abstracts are given for 26 abbreviated tables for spectrochem. analysis; for 5 tables of standard wave lengths; and for 7 charts and atlases of spectra. The limitation of present wave-length data is discussed. L. W. Strock

Astronomical spectra—modern observation and inter-

pretation. Otto Struve. *J. Applied Phys.* **10**, 800–16 (1939).—A general paper describing the use of temp. and pressure parameters as obtained by an analysis of stellar spectra in classifying stars. Characteristic features of normal and anomalous stellar spectra are described, such as the simultaneous occurrence of the absorption lines of normal stars and emission lines of H and ions of other elements in spectra of the same star. The astronomical interpretation of the width of emission lines of various types of stars, and the advances in observational technique at the principal observatories of the world are described. L. W. Strock

Atmospheric absorption. Arlette Vassy and E. Vassy. *J. phys. radium* **10**, 403 12(1939).—The absorption of light for both the total atm. and the lower atm. was measured over the range 3000–8300 A.; it follows accurately the Rayleigh-Cabannes scattering law, with superimposed bands due to the various atm. constituents. Unknown bands at 4400, 3850 and 3600 A. varied in intensity from night to night and are attributed to H_2O. A. O. Allen

The arc spectrum of nitrogen. (N I) II-A. Extreme ultraviolet region. Masahide Kamiyama. *Sci Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 375-81(1939).—The N I spectrum is photographed in the extreme ultraviolet with a 1-m. grating spectrograph of Siegbahn type giving a dispersion of 6 A./mm. in the first order. A He pressure of about 18 mm. Hg and a partial pressure of N ranging from 0.05 to 0.1 mm. were found to be the best condition for developing the arc spectrum of N. About 120 of the 237 lines measured between 1836.70 and 855.70 A. are new. A majority of the lines are classified but a discussion of this classification is reserved for Part III. W. F. Meggers

The Stark effect of Hg I. Yosio Isida and Sigeru Hiyama. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 390–416(1939).—A discharge tube of simple Lo-Surdo form is used to study the Stark effect of Hg lines in elec. fields up to 560,000 v./cm. In the elec. field the relative intensities of most lines are similar to those of the arc spectrum but lines violating both Δl and Δj selection rules become stronger. Results for more than 100 Hg I lines involving singlet and triplet terms are presented in tables and diagrams. W. F. Meggers

The Stark effect of C I. Yosio Isida, Tadasi Tamura and Masaiti Hukusima. *Sci. Papers Inst. Phys. Chem. Research* (Tokyo) **36**, 417–18(1939). Since no data on the Stark effect in the C I spectrum have ever been published, results are given here for a dozen lines (4110 to 5052) investigated in elec. fields of 125,000 to 421,000 v./cm. W. F. Meggers

Molecular emission spectra. G. H. Dieke. *J. Applied Phys.* **10**, 780–99(1939). A comprehensive paper covering the following aspects of the emission spectra of diat. mols.: (1) energy levels of diat. mols., (2) structures of band spectra and (3) application. The application of the band-spectrum data in detg. isotopes, heat of dissocn. and nuclear spin is reviewed. References to 8 general papers and books are given. L. W. Strock

Infrared spectra—observation and uses. H. M. Randall. *J. Applied Phys.* **10**, 768–79(1939).—A general paper with 19 references. L. W. Strock

A push-pull photoelectric photodensitometer for determining fine structure in ultraviolet absorption spectra. John R. Loofbourow. *J. Optical Soc. Am.* **29**, 535–7 (1939). E. H.

Far infrared absorption spectrum and the rotational structure of the heavy water vapor molecule. Nelson Fuson, H. M. Randall and D. M. Dennison. *Phys. Rev.* **56**, 982–1000(1939); cf. *C. A.* **31**, 7755[4].—The absorption spectrum of D_2O vapor was studied between 23 and 135 μ; measurements were made of wave length and relative intensity of 210 pure rotation lines. The energy levels of a zero-order approximation to the D_2O asym. rotator were calcd. through $J = 11$ and corrected for zero-point vibration and centrifugal stretching in the ground state. The observed spectrum was then used to obtain more exact energy levels, the correctness of the assignments being assured by series regularities and combination relations. The resulting 111 energy levels were then used to compute a theoretical spectrum, which is compared with the exptl. one. G. M. Murphy

Infrared absorption spectra of some monosubstituted naphthalenes. Jean Lecomte. *J. phys. radium* **10**, 423–7 (1939).—See *C. A.* **33**, 5741[9]. H. Game

Rotation-vibration energies of tetrahedrally symmetric pentatomic molecules. II. Wave H. Shaffer, Harald H. Nielsen and L. H. Thomas. *Phys. Rev.* **56**, 1051–9 (1939); cf. *C. A.* **33**, 5280[4]; **34**, 675[9].—A general Hamiltonian, including all terms through the second order, is applied to the states $2\nu_3$, $2\nu_4$ and $\nu_3 + \nu_4$ of the mol. XY_4 (ν_3 and ν_4 are the triply degenerate vibrations belonging to the representation, T_2 of the symmetry group Td). Wave functions, selection rules and matrix elements, have been obtained. G. M. Murphy

Infrared absorption studies. IX. Bonding of hydrogen in nitrogen compounds. A. M. Buswell, J. R. Downing and W. H. Rodebush. *J. Am. Chem. Soc.* **61**, 3252–6 (1939); cf. *C. A.* **32**, 8932[9]; **33**, 9141[3].—The absorption due to the N-H group is distinctly weaker than for the O-H group and there is a much greater variability in the characteristic frequency. Infrared absorption is a less-reliable criterion for bonding of H attached to N than for H attached to O. There is no pos. proof of assocn. involving the formation of N-H → N bonds but there is a strong tendency toward assocn. if the H is somewhat acidic. The characteristic absorption produced by assocn. of mols. contg. the peptide linkage may be due to an enolized H. A. B. Garrett

Infrared studies of the porphyrin molecule. C. S. Vestling and J. R. Downing. *J. Am. Chem. Soc.* **61**, 3511-13(1939).—The infrared absorption of 2 dipyrrylmethenes, the Cu complex of one of them, etioporphyrin I, and etiohemin I chloride has been measured. Replacement of the acidic hydrogens with metal atoms eliminated N-H absorption in the dipyrrylmethenes and in etioporphyrin I. The data do not give conclusive evidence that N-H-N bonding exists in these mols. but it is concluded that absorption peaks occur at frequencies which might be expected if N-H-N bonding were existent in the porphin and dipyrrylmethene nuclei. A. B. Garrett

Absorption of inorganic colored salt solutions in the near infrared. Th. Dreisch and O. Kallscheuer. *Z. physik. Chem.* **B45**, 19–41(1939).—Aq. solns. of the following salts gave absorption max. at the wave lengths noted (in A.): $TiCl_3$, $TiBr_3$, 7440; $VOCl_2$, $VOSO_4$, VCl_2, VSO_4, 8400; $V_2(SO_4)_3$, VCl_3, 6100; $CrCl_2$, $CrBr_2$, 7920; $FeCl_2$, $FeBr_2$, $FeSO_4$, $FeSO_4.(NH_4)_2SO_4$, 9700; $FeBr_3$, $FeCl_3$, 7740; $MnCl_2$, no absorption between 6000 and 16,000; UO_2SO_4, UO_2Cl_2, UO_2Br_2, $U(SO_4)_2$, UCl_4, UBr_4, absorption with fine structure between 7000 and 9000 and between 13,000 and 18,000, with no fine structure between 10,000 and 12,000. Many of the other bands also showed some fine structure. G. M. Murphy

Raman spectra of acetylenes. II. Displacements and depolarization factors for phenylacetylene and derivatives of the type $C_6H_5C{\equiv}CR$. M. J. Murray and Forrest F. Cleveland. *J. Am. Chem. Soc.* **61**, 3546–9(1939); cf. *C. A.* **33**, 1596[3].—The R group in these compds. was H, Cl, CH_3, C_2H_5, CH_2OH, CH_2Cl, CH_2Br, CH_2CH_2OH, CH_2CH_2Cl, $CH(OH)CH_3$, $CH_2C_6H_5$ and $CH_2CH_2CH_2Cl$. The 2 lines near 2200 cm.$^{-1}$ were found to have the same depolarization factors; this indicates that one frequency cannot correspond to a sym., and the other to an asym. vibration as Glocker and Davis (cf. *C. A.* **28**, 7159[9]) have stated to be the case for dimethylacetylene. A. B. G.

Raman spectra. CVII. Methylene derivatives. J. Wagner. *Z. physik. Chem.* **B45**, 69–91(1939); cf. *C. A.* **32**, 8937[9]; **33**, 8117[5,6,7,9].—Raman spectra and depolarization measurements were obtained for YCH_2X where Y, X = Cl, Cl; Br, Br; I, I; Cl, Br; Cl, I; Br, I; Me, Cl; Me, Br; Me, I. Selection principles were detd. for the symmetry C_{2v} and C_s and the frequencies were assocd. with normal vibrations. The mol. consts. were detd. for H_2CCl_2, H_2CBr_2 and H_2CI_2. Simple valence forces are applied to the mol. H_2CX_2. G. M. Murphy

The nature of the low-frequency Raman spectrum and

the spectrum of the hexamethylbenzene crystal. E. F. Gross and A. I. Raskin. *Compt. rend. acad. sci. U. R. S. S.* 24, 126–8(1939)(in English).—In the Raman spectrum of a single crystal of C_6Me_6 2 bands were found at frequencies of 53 and 95 cm.$^{-1}$. The existence of these bands supports the conclusion of Gross and Vuks (*C. A.* 30, 5128[1]) that the low-frequency Raman spectrum results from intermol. oscillations of the crystal lattice.
T. H. Dunkelberger

Low-frequency scattering spectra in *p*-, *m*- and *o*-diiodobenzenes. E. F. Gross and A. V. Korshunov. *Compt. rend. acad. sci. U. R. S. S.* 24, 328–31(1939)(in English).—The new type of scattering spectrum observed in crystals of org. substances is probably due to the intermol. vibrations, translational and angular, within the cryst. lattice. A true test of the theory seems possible only by the comparison of the spectra of substances having the same structure but contg. different isotopes but an approach to the solution of the problem is made with *p*- (I), *m*- (II) and *o*- (III) $C_6H_4I_2$, which have the same mass but different structures and consequently different moments of inertia. The cryst. lattices of I and II are known to be closely related, that of III, less completely known, is similar. The low-frequency Raman lines in cm.$^{-1}$, obtained with monocrystals at room temp. with the ultraviolet portion of the spectrum absorbed by 10% $NaNO_2$ in H_2O are: I 15, 25, 115; II 24, 79, 101; III 23, 46, 74, 89, 100, 127. The agreement in the frequencies for the 3 compds. is explained as due to the fact that all 3 have the same mass, i. e., they are the translational vibrations of the whole mols. in the crystal lattice. The noncoincidence of the other lines should then possibly be put down to the angular vibrations of the whole mols.
Janet E. Austin

The molecular structures of sulfuryl fluoride and thiophosphoryl fluoride. D. P. Stevenson and Horace Russell, Jr. *J. Am. Chem. Soc.* 61, 3264–8(1939).—Electron-diffraction investigation of these compds. gave the following interat. distances and bond angles: for sulfuryl fluoride, S – F = 1.56 ± 0.02 A., S – O = 1.43 ± 0.02 A., ∠F – S – O = 105 ± 2°, and ∠F – S – F = 100 ± 10°; and for thiophosphoryl fluoride, P – F = 1.51 ± 0.02 A., P – S = 1.85 ± 0.02 A., ∠F – P – F = 9.95 ± 2°, and F – P – S = 118 ± 2°. The relationship between the structures found and the resonating valence bond structures is briefly discussed.
A. B. Garrett

Present status of radiography by photographing the fluorescent screen image. H. Franke. *Phot. Ind.* 36, 1291(1938).
E. R. B.

The influence of temperature on the ultraviolet luminescence spectrum of sodium chloride and potassium chloride crystals. M. N. Podashevskiĭ and A. M. Polonskiĭ. *Compt. rend. acad. sci. U. R. S. S.* 24, 332–3(1939)(in German); cf. *C. A.* 33, 4522[6].—The ultraviolet luminescence spectra of tempered rock salt crystals and synthetic KCl crystals, colored by light from a condensed Al spark or by x-rays, were detd. in a high-vacuum chamber in a Dewar flask fitted with thin quartz and fluorite windows. The luminescence band is broadened at the higher temps. and the max shifted toward the long wave lengths. The max. of NaCl and of KCl, resp., are: −180°: 244, 270; 15°: 249, 280; 100° 252, 286 mμ. The curves are given.
Janet E. Austin

The potential-energy relationships in normal and excited acetaldehyde. Thomas W. Davis and Milton Burton. *J. Chem. Phys.* 7, 1075–80(1939); cf. *C. A.* 33, 5743[4].—Math. The following effects are explained: (1) the dependence on temp. and wave length of the probabilities of free radical and ultimate mol. production in the primary photochem. act; (2) the disappearance of fluorescence at shorter wave lengths or at higher temps.; (3) the sep. maxima for bond and continuous absorption; (4) the high quantum yield at 3340 A.
G. M. Petty

Thermal and photochemical exchange reactions of bromine. J. Norton Wilson and Roscoe G. Dickinson. *J. Am. Chem. Soc.* 61, 3519–20(1939).—Investigation of the exchange of Br between radioactive Br and various Br compds. has led to the following results: a rapid exchange occurs with $AsBr_3$ and $SnBr_4$ at room temp. in CCl_4 soln.; in the same solvent no exchange, beyond the limits of exptl. uncertainty, was observed to occur with either ethylene bromide or trichlorobromomethane in the dark at 100°; a rapid exchange with trichlorobromomethane is induced by green light at 76°. A method is described for the prepn. of dil. and highly radioactive solns. of Br_2 in CCl_4.
A. B. Garrett

The photochemical decomposition of solid hydrogen compounds at low temperatures. L. Farkas, Y. Hirshberg and L. Sandler. *J. Am. Chem. Soc.* 61, 3393–6(1939).—Para-hydrogen is formed when solid HI is irradiated at low temps. An explanation for this is that the hydrogen primarily formed can be converted by the paramagnetic action of free I atoms, or the heat formed in the reaction $H + HI_{solid} = H_2 + I$, is dissipated in the solid. In the photolysis of HCHO and CH_3OH, under the same conditions, normal hydrogen is formed. This suggests that the 2 hydrogen atoms forming a mol. come from the same mol. of HCHO or CH_3OH.
A. B. Garrett

The photochemical formation of trichlorobromomethane from chloroform and bromine. V. Braunwarth and H. J. Schumacher. *Kolloid-Z.* 89, 184–94(1939).—The reaction of $CHCl_3$ and Br to give HBr and CCl_3Br was induced by 5460-A. light and the reaction kinetics were studied at 110° and 130° and pressures of 40–400 mm., the compn. of the reacting mixt. being varied and HBr, CCl_3Br and N added in varying amts. Quantum yields were around 19. The reaction rate is given above 200 mm. total pressure by $k[I_{abs.}]^{1/2}[CHCl_3]/P^{1/2}\{1 + (k'[HBr]/[Br_2])\}$ and below 90 mm. by $k[I_{abs.}][CHCl_3]P/\{1 + (k'[HBr]/[Br_2])\}$ where P is the sum of the pressures of reactants and products plus half the pressure of N. In going from 110° to 130°, k approx. doubles, but k' remains const. A slight inhibition by added CCl_3Br is also found in the later stages of the reaction. All the data are very neatly explained by a reaction mechanism similar to those found for the photochem. formation of CCl_4 from $CHCl_3$ and Cl, and of HBr from H and Br (cf. *C. A.* 30, 7041[2]).
A. O. Allen

A photocalorimeter. The quantum efficiency of photosynthesis in algae. John L. Magee, Thomas W. DeWitt, Elizabeth Coolidge Smith and Farrington Daniels. *J. Am. Chem. Soc.* 61, 3529–33(1939).—A small calorimeter is described capable of measuring a rate of heat change as small as a millionth of a caloric per second. It is designed to admit light and thus give a measurement of heat changes accompanying photochem. reactions. It consists of a small thin-walled quartz cell mounted in a cylindrical Al container. The heat evolved or absorbed in a chem. reaction taking place in the calorimeter can be obtained by comparing the galvanometer-time curve with the curve for a chemically inert material under similar conditions. The calorimeter has been used to measure the thermal efficiency of photosynthesis by green algae. About four fifths of the red light absorbed in living algae is converted into heat, with a quantum yield of about 0.08 mol. per quantum absorbed.

Radley, J. A., and Grant, J. Fluorescence Analysis in Ultra-Violet Light. Vol. II. 3rd ed., revised and enlarged. Edited by E. Howard Tripp. London: Chapman & Hall. 424 pp. 22s. 6d.

Fluorescent material suitable for coatings. Carl Pfanstiehl (to Pfanstiehl Chemical Co.). U. S. 2,176,090, Oct. 17. A fluorescent material such as Zn silicate is prepd. in the form of individual unground crystals substantially all of which are of the order of one micron in size.

U. S. 2,176,100 relates to a fluorescent powder which may comprise Zn Be silicate in the form of unground crystals substantially all less than 2 microns in size and activators including a rare earth metal such as La, Sm or Nd and MnO_2.

Fluorescent screen. Gorton R. Fonda (to General Elec. Co.). U. S. 2,177,701, Oct. 31. A light-modifying screen adapted to improve the spectrum of impinging radiations deficient in red comprises a base carrying a coating in layers of a material contg. a substantial quantity of rhodamine alternating with layers formed mainly of cellulose acetate.

Luminescent bodies for excitation. Wilfried Meyer (to General Elec. Co.). U. S. 2,177,735, Oct. 31. A luminescent body capable of light emission under excitation of ultraviolet rays includes a conductive carrier of ZnO with a surface contg. Zn, SiO_2, Mn and O, which is luminescent.

4—ELECTROCHEMISTRY

COLIN G. FINK

Basic problems in electrochemistry. A. N. Frumkin and V. A. Pleskov. *Sbornik "Matem. i Estestvozn. v S. S. S. R."* **1938**, 401–15; *Khim. Referat. Zhur.* **2**, No. 4, 3 13–14(1939).—A review of the most important electrochem. investigations in U. S. S. R. for the last 20 years. Considerable progress was made in the electrochemistry of nonaq. solns. (relation between elec. cond. and the formation of complexes); properties of liquid-NH_3 solns.; theory of aq. electrolytes; nature of electrodeposition; mechanism of reactions in the elec. discharge through gases; potential drops at different phase boundaries; problems of surface phenomena; theory of electrode proc- 4 esses; measurements of dipole moments and problems of applied chemistry (development of different types of storage batteries, methods of electrolysis of fused salts, electrosyntheses, etc.). W. R. Henn

Top-charge rapid-type furnaces in the manufacture of plain carbon steels. H. H. Watson. *Can. Metals Met Inds.* **2**, 308–10(1939).—The top-charge type of elec. furnace shows substantial savings in power, electrode and re- 5 fractory costs. Cost of refractories for the fixed-roof furnace was 30% greater than for the top charge furnace and electrode consumption was 14% lower for the top-charge furnace. W. H. Boynton

Electric drying ovens for lacquers liable to detonate. K.-A. Lohausen and G. Schumann. *Elektrowärme* **9**, 231–8(1939).—Elec. ovens are particularly suitable for drying lacquers giving off vapors which can form explosive 6 mixts. with air. The heating units can be so designed that their temp. can be safely kept below the ignition temp. of the vapors. Suitable ovens are described. M. H.

Determination of the electromotive force of the electrolytic cell aluminum ‖ carbon in fluorides and chlorides. Yu. V. Baĭmakov and N. R. Ishmaev. *Trans. Leningrad Ind. Inst.* **1938**, No. 1, Sect. Met. No. 1, 81–96.—The e. m. f.s of the following electrolytic cells were detd.: (1) Al ‖ C in cryolite + Al_2O_3 melts in atm. of H and A at 890–1100°; (2) Al ‖ C in chlorides at 680–900°. The thermal 7 data calcd. are close to the heat of formation of Al_4C_3 as obtained by other authors. The measurements in A corresponded to those in H. B. Z. Kamich

Stability of iron oxide and copper oxide anodes in the electrolysis of cryolite-alumina melts. Yu. V. Baĭmakov, K. P. Batashev, L. M. Evlannikov and A. I. Bukhbinder. *Trans. Leningrad Ind. Inst.* **1938**, No. 1, Sect. Met. No. 1, 57–80.—Anodes were tested for stability in the electrolysis 8 of cryolite alone or cryolite with 5% Al_2O_3 or with 10% NaF. The chem. soln. of the Fe_2O_3 anodes did not exceed 0.24%; Cu oxide anodes, 0.15–0.20%. The soly. of the anodes during electrolysis was then detd. and they were found to be unstable. B. Z. Kamich

Electrolytic production of lead-barium alloys. K. P. Batashev and M. A. Vinogradova. *Trans. Leningrad Ind. Inst.* **1938**, No. 1, Sect. Met. No. 1, 50–6.—Pb-Ba alloys of high purity were obtained by electrolyzing a 9 melt of 20–70% $BaCl_2$ and 80–30% KCl by wt. in Fe cells lined with burnt clay or talc-schist. The cathode c. d. was 0.3–0.5 amp./sq. cm., spacing between electrodes, 15 to 100 mm., best temp. 700–750°. The molten Pb cathode can be satd. with Ba up to 15% without affecting the electrolysis provided stirring of the Pb is resorted to from time to time. The anode was graphite. B. Z. K.

Anode slime formation during the refining of copper. A. Glazunov. *Chem. Listy* **33**, 352–4(1939).—G. analyzes the anode slimes, explains the process of slime formation, and divides the products into primary and secondary phases. In the primary phase are the insol. compds.: Cu_2O, Cu_2S, Cu_2Te. To the secondary phase belong (*a*) the noble metals Ag, Au, Pt and other metals of the Pt group which have a potential more noble than that of Cu; (*b*) products of the reaction of sulfate that are insol. ($PbSO_4$); (*c*) other products of anodic oxidation; (*d*) products formed by the hydrolysis of elements as Bi hydrate or Sb-HCl and (*e*) metallic powders formed from ions of multivalence: $2Cu^+ \rightleftharpoons Cu^{++} + Cu$ or more rarely $3Au^+ \rightleftharpoons Au^{+++} + 2Au$. Frank Maresh

A modern electroplating plant. Fauvelot. *Electricité* **23**, 310–12(1939).—F. describes a modern plant for mass production of small articles Ni, Cr and Cd plated. J. M. Noy

Chromium-plating baths containing fluoride ions. Yu. V. Baĭmakov, K. P. Batashev and D. M. Telenkov. *Trans. Leningrad Ind. Inst.* **1938**, No. 1, Sect. Met. No. 1, 27–35.—The baths contained 250 g./l. of CrO_3, 0.5–10 g./l. of NaF and less than 1 g./l. of sulfate. Temps. were 15–45° and c. d. 1–5 amp./sq. dm. Best deposits were obtained in baths contg. 2–5 g./l. of NaF and at a c. d. of 1–5 amps./sq. dm., while in some cases bright deposits were obtained with c. d. of 0.5 amps./sq. dm. Deposits obtained at 18–30° were bright. Max. thickness of these deposits was 6–8 microns. The throwing power of the bath contg. CrO_3 250 g. and NaF 5 g./l. was detd. at 21–22° and at a c. d. of 3 amp./sq. dm. With increasing temp. the throwing power dropped and at 35° it was 16%. Pb anodes deteriorated rapidly; Pt and magnetite (treated in a Cr bath for 48 hrs.) anodes were good for long periods. B. Z. Kamich

Improvement in the acid sulfate and fluoborate cadmium baths so that they may replace the cyanide bath. V. I. Lainer, S. I. Orlova and A. M. Faĭgel'shteĭn. *Korroziya* **4**, No. 2, 96–114(1938); *Khim. Referat. Zhur.* **2**, No. 2, 138 (1939).—Coarse cryst. deposits are formed in the acid Cd bath (addn. agents being absent) owing to insufficient cathodic polarization. In order to increase the cathodic polarization and to obtain a fine-grain Cd deposit, the addn. of colloids (peptone, glue, creosol) to the acid Cd bath was investigated at different pH values and c. ds. The Fe cathodes were pickled in concd. HCl, degreased with Vienna lime and carefully washed. Anodes were rolled Cd plates with a surface 1.5–2 times as large as the cathode surfaces. The structure of the ppt. was studied under a microscope (× 100) and in each case compared with the structure of the ppt. obtained from a $Cd(CN)_2$ bath connected in series with the acid bath. The following compns. of the bath were used, in g./l.: $CdSO_4 \cdot {}^8/_3H_2O$ 64, $(NH_4)_2SO_4$ 33 and $Al_2(SO_4)_3 \cdot 18H_2O$ 28. Bath temp. 18–20°. In all cases the Cd plate was 0.01 mm. thick. The cathode efficiency was 96–98%. From the peptone-contg. bath the finest-grain structure and dense deposits were obtained at a concn. of 0.5 g./l. of peptone with a c. d. of 0.5–1 amp./sq. dm. and pH 2–3.2. The optimum conditions for creosol were a concn. of 8 g./l. of creosol, pH 1.5–3.3, c. d. 0.5–0.8 amp./sq. dm. The densest and finest deposits from a H_2SO_4 bath were with glue. For best results the concn. of glue is 0.5 g./l., c. d. 0.5–1.0 amp./sq. dm., pH 3.0–5.5, temp. 18–20°. The

Cd + HBF_2 bath was operated at 20° and at 50°, c. d. up to 10 amp./sq. dm. with an addn. of 1 g./l. glue. Finest-grain deposits were obtained from $Cd(BF_4)_4$ 143 g./l., HBF_2 35, glue 1, c. d. 9–10 amp./sq. dm. temp. 50°. The current efficiency was 96–98%. The HBF_2 bath is superior to the others because it permits use of a high c. d. The throwing power of the acid Cd bath is considerably smaller than that of the CN bath. The Cd plates from an acid bath have a fine-grain structure and give the same protection of the steel against corrosion as the plates from a CN bath. W. R. Henn

High-speed copper plating. Details of the development of a process for cyanide solutions. F. F. Oplinger. *Metal Ind.* (London) **55**, 335–8, 375–7(1939).—See *C. A.* **33**, 4134⁹. H. Game

The polarization of quinhydrone electrodes. V. Čupr and A. Čížek. *Chem. Listy* **33**, 321-5(1939)(French summary).—From continuously and automatically-recorded voltage *vs.* time graphs Č. concludes that the voltage, π, in the cells (quinhydrone nonpolarized: quinhydrone polarized) is not a log function of the time. The exptl. results and graphs did not substantiate any other relations which could be derived from the fundamental Fick law for diffusion processes. Further analyses revealed that this discrepancy does not lie in the Fick law but in the fact that during the polarization of the quinhydrone electrode, local galvanic cells are formed which modify the value of π. Whenever the quinhydrone electrode became polarized cathodically, H as well as hydroquinone formed in the electrode which acquired some of the characteristics of a H electrode. Even with a polarized quinhydrone electrode the potential of the H electrode was present; for this reason it was not possible to substantiate the Fick law. The change in π with time depends not only upon the diffusion of the hydroquinone but also upon the intensity of the local cells. Frank Maresh

Kinetics of the oxidation-reduction potentials. I. A. Rotinyan. *J. Gen. Chem.* (U. S. S. R.) **9**, 1182-7 (1939).—The potentials of mixts. of H_3AsO_4 and H_3AsO_3 in basic and in acid mediums were measured by Raps compensator with a precision of 0.0001 v. in a water thermostat at 25 ± 0.05°. The reference electrode was Hg | Hg_2SO_4, 0.1 *N* H_2SO_4; unplatinized Pt electrodes of the Wink- type were used as inert electrodes. Attempts to obtain equil. potentials for the H_3AsO_4 and H_3AsO_3 mixts. during 24 hrs. in a basic soln. were not successful. No reproducible potentials were obtained in the presence of the ions of I. In acid solns. under suitable conditions it was possible to obtain equil. potentials; this is in agreement with F. Forster and Pressprich (*C. A.* **21**, 2596). In the presence of KI the electrode potential did not depend on the concn. of KI. In acid solns. in the presence of KI equil. potentials are obtained. Four tables, 1 graph and 19 references are given. II. *Ibid.* 1188–97.—The kinetics of the equil. oxidation-reduction potentials of H_3AsO_4 and H_3AsO_3 at polarized cathodes were investigated by potential-time curves. It was verified that the velocity of the establishment of equil. potentials increases with an increase of the acidity of the soln. and with the concn. of the ions of I which transfer the potential. For the first time it was found that the velocity increases with increase in ratio of the concn. of H_3AsO_4 to the concn. of H_3AsO_3. The equil. potentials at the electrodes consisting of a thin layer of Pt on glass were reached very rapidly. The effect of poisoned electrodes on the equil. oxidation-reduction potentials was developed. Wagner's hypothesis of surface reactions (as a time-detg. factor of the process) contradicts the expts. of Zhukov as well as those of R. If the potential As^{+++++}/As^{+++} is considered as a H potential in the supposition that the process of the diffusion of H to the surface is the time-detg. process, the relation between the time necessary for the establishment of equil. and the ratio of H_3AsO_4 concn. to H_3AsO_3 concn. can be deduced theoretically. Four tables, 5 diagrams and 11 references are given. III. *Ibid.* 1198–1206.—The velocity of the establishment of equil. potentials increases with an increase of the ratio of H_3AsO_4 concn. to H_3AsO_3 concn. The values of the equil. potentials and the curves of potential *vs.* time do not depend on the method of oxidation of the electrode (by immersion in HNO_3 or by cathodic polarization). The time necessary for the establishment of the equil. potentials on the oxidized electrode is proportional to the logarithm of time necessary for the establishment of the equil. potential on the polarized cathode. Nine diagrams, 4 tables and 4 references are given. W. R. Henn

Electrochemical purification of water for storage batteries. M. M. Likhachev. *Elektrichestvo* **60**, No. 3, 26–30(1939).—In various electrochem. methods of treating water the cations Na, Ca and Mg are removed in order of increasing difficulty; for anions the order is Cl, SO_4, CO_3 and SiO_2. Colloidal SiO_2 is not removed by electrochem. means, while org. compds. are removed only incompletely. If present in large amts. org. compds. should first be coagulated. Various app. are illustrated (cf. Jean Billiter). B. Z. Kamich

Resistors and condensers in mass production. Herbert Chase. *Electronics* **12**, No. 9, 28–31(1939).—Description of the Erie Resistor Corp. process. Two forms of resistors are made, in a variety of sizes and resistance values, but all having as the essential resistor a cylindrical bar (3-mm. diam.) of C. The ends of the bars are Cu coated, by the spray method, to ensure good contact with the wire terminals. Finely powd. C is mixed with inert materials in various proportions to procure the desired ohmic resistance. A binder is added and the bars are formed in a tableting machine. The bars are then baked, and next automatically sorted according to their resistance. Then follows the painting of body, tip and dot, as required by the marking code. The final step is the sealing of the C bar into a ceramic shell. The fixed condensers are of 2 types: one with Ag plates in intimate contact with a ceramic dielectric, and the other with Ag plates and mica as dielectric. Those with the ceramic dielectric have a definite linear and reproducible temp. coeff. and are widely used in tuned oscillator circuits to compensate for changes in frequency due to temp. variations. One type has a pos temp. coeff. of 0.00012 per 1°; another type with a TiO_2 dielectric has a neg. temp. coeff. of 0.00068 per 1°. Others have coeffs. lying between these 2 limiting values. TiO_2 has a high dielec. const. (85), and accordingly fairly large capacities are obtainable in a rather small unit. The Ag is applied to the ceramic surface by coating the surface with a Ag soln., drying and heating to high temp. in a reducing atm., converting the Ag salt into Ag metal. Every condenser is carefully tested and calibrated. C. G. F.

Recovery of slag with high content of V in basic Bessemer and its use in elec.-arc furnace (Harr) **9**. Organic acids [by elec. process] (U. S. pat. 2,176,343) **10**.

Storage-battery plates. Willis A. Gibbons and Eardley Hazell (to United States Rubber Products Inc.). U. S. 2,177,062, Oct. 24. Finely divided highly microporous hard rubber is used as a porosity agent in a paste of finely divided active material.

Storage-battery retainers. Wm. E. Kershaw (to Elec. Storage Battery Co.). U. S. 2,176,427, Oct. 17. A perforated storage-battery retainer the thickness and perforation dimensions of which remain const. is made of a vinyl resin which in contact with PbO_2 resists disintegration under the electrolytic action to which it is exposed in a storage battery. U. S. 2,176,428 relates to tubular retainers made of fabric consisting of threads of a synthetic vinyl resin.

Electrolytic condenser. Anthonius F. P. J. Claassen and Cornelis de Lange (to N. V. Philips' Gloeilampenfabrieken). U. S. 2,177,018, Oct. 24. Various structural

details of a condenser with a liquid electrolyte such as a glycerol soln. of NH_4 borate and electrodes which may be formed of Al. Cf. *C. A.* **33**, 2421[7].

Electrical condensers. Paul Schupp and Fritz Wilke (to Siemens & Halske A.-G.). U. S. 2,177,266, Oct. 24. Alternating layers of foil electrode material such as Al foil and a polymeric dielectric such as polystyrene are wound upon themselves with the dielec. material in expanded condition, and the wound roll is subjected to heat treatment sufficient to transform the dielec. material to a lesser degree of expansion with elimination of air enclosures

Electrodes for electrolytic condensers, etc. Joseph S. Williams (to P. R. Mallory & Co.). U. S. 2,177,086, Oct. 24. A predetd. section of an electrode metal surface such as one of Al foil is immunized to etching action, as by coating with paraffin, and the metal surface is exposed to an etching medium so as to etch the portions of the surface which have not been immunized, and an electrode terminal is formed out of the unetched portions

Electroplating apparatus. Arthur J. Donald. U. S. 2,177,453, Oct. 24. Various structural details.

Electroplating with silver. Birger Egeberg and Nathan Promisel (to International Silver Co.). U. S. 2,176,668, Oct. 17. In a Ag cyanide plating bath, a brightening agent is used such as urea or other compd. of the general formula $X\text{-}CO\text{-}NH_2$ in which X represents NH_2 or a substituted NH_2 group contg. Me, Et, Ac or NH_2 as substituents.

Chromium-plating. John R. Mardick. U. S. 2,177,392, Oct. 24. A method of Cr-plating articles involves connecting the articles as cathode in an aq. electrolyte contg., per l., chromic acid 60–300 g., $Na_2Cr_2O_7$ 100–350 g. and some sulfate present as impurities and within the range of 0.5 g. to 12 g. per l., operating the bath at a c. d. of 15–140 amp. per sq. ft. and at a temp. of 20–45°, periodically adding chromic acid and $Na_2Cr_2O_7$ to compensate for their depletion, and continuing the plating while allowing the sulfate content to increase to not over about 12 g. per l.

Coating ferrous metals with tin. Elgin C. Domm (to National-Standard Co.). U. S. 2,176,066, Oct. 17. An article to be protected against corrosion, such as a sheet or wire, is immersed in a molten metallic bath predominantly composed of Pb and Sb, and then electroplated with Sn of a thickness of about 0.0001–0.0002 in

Electrolytic cell assembly suitable for the manufacture of persulfuric acid and its salts. Josef Müller (to Oesterreichische chemische Werke G. m. b. H.). U. S. 2,177,626, Oct. 24. Various details of an app. with cells one above another in a "filter-press-like" arrangement.

Electric apparatus for controlling the concentration of solutions. Edward H. Pyle and Thomas E. Ross (to Calif. Packing Corp.). U. S. 2,176,471, Oct. 17. Various elec. and operative details of an app. suitable for automatic control of the strength of salt and lye solns. employed in fruit peeling app., etc.

Multi-cell electrochemical generator with single electrolyte. Gunnar A. F. Winckler (to Winckler Engineering Laboratories Inc.). U. S. 2,177,235, Oct. 25. Various structural details.

Treating ores, such as hematite, with high-frequency electric currents. Hideyuki Kikuti (to Nippon Koshuha Jukogyo K. K.). U. S. 2,177,070, Oct. 24. A method of reducing ores such as those of Fe, Mo, Pb, Ti, etc., involves mixing the granulated electrically nonconductive ores with an amt. of granulated at least partly electroconductive reducing agents at least equal to that theoretically necessary to reduce the charge and in a proportion to the latter to produce a powderous mixt. having discontinuous electroconductive properties, and subjecting the mixt. in an electrode furnace to the action of a high-frequency current having a voltage above 1000 v and a frequency of at least 100,000, whereby numerous minute local discharge sparks are generated in the mixt. Reducing agents such as graphite or coke may be used.

Alloys containing beryllium. Bengt R. F. Kjellgren and Charles B. Sawyer (to Brush Beryllium Co.). U. S. 2,176,906, Oct. 24. A method of forming alloys contg. Be and a heavy metal such as Cu, Ni, Cr or Fe capable of alloying with Be at a temp. at which Be oxide is reducible with C involves maintaining in a suitable chamber an elec. arc adjacent to the surface of a molten bath of alloy such as it is desired to form, progressively introducing into the zone immediately surrounding the arc a loose mixt. contg. finely divided C and Be oxide of such a degree of purity that its apparent d. after being heated to 1000° for the first time does not exceed 0.4, for production of Be with evolution of CO; and meanwhile progressively introducing into the top of the molten bath small pieces of the heavy metal. App. is described.

Calcium carbide. Ernst Winter, Franz Lückerath and Paul Windelband (to Akt.-Ges. für Stickstoffdünger). U. S. 2,177,621, Oct. 24. See Ger. 677,461 (*C. A.* **33**, 6732[2]).

Television transmitting tube. Harold Miller (to Electric & Musical Industries Ltd.). U. S. 2,177,736, Oct. 31. A target electrode for a cathode-ray television transmitting tube comprises a conductive signal plate having on its surface a layer of photoelectrically conductive material such as Cu oxide which is nonphoto-emissive, and a coating on this layer of a borate of an alkali metal.

Electric switch contacts. Newton C. Schellenger (to Chicago Telephone Supply Co.). U. S. 2,177,288, Oct. 24. Contacts are formed of conductive metal such as a Cu alloy provided with a plating of Ag and an overlying plating of Sn which is thin and adapted to be worn away quickly in use of the contact, but which previously serves to facilitate soldering.

Electric discharge device. Gilles Holst (to General Elec. Co.). U. S. 2,176,134, Oct. 17. A device suitable for operation at high temps. comprises a sealed envelope contg. electrodes, a gaseous atm. within the envelope consisting of Ne with an admixt. of a small proportion of A, and a sealed jacket about the envelope contg. N mixed with a small proportion of Ne so that the Ne concn. within the sealed envelope is maintained substantially const. despite long-continued maintenance of the envelope at a temp above that at which Ne will diffuse through it.

Electric discharge devices. Walther Dawihl, Otto Fritze and Alfred Rüttenauer (to General Elec. Co.) U. S. 2,177,691, Oct. 31. The wall of an elec. discharge device of luminescent character is formed of colored and transparent material such as glass and is provided with an internal coating consisting of the product of reaction between the container material and a soln. of an acid of an element of the fifth group of the periodic system such as H_3PO_4 and with a luminous material such as Zn silicate on the coating, the device being provided with electrodes and a filling of gas.

Gaseous electric discharge device suitable for supplying ultraviolet rays. Hermann Krefft, Kurt Larche and Max Thomas (to General Elec. Co.). U. S. 2,177,728, Oct. 31. A gaseous elec. discharge device comprises a container, electrodes sealed therein, a gaseous atm. therein, and a quantity of vaporizable material therein which emits visible and ultraviolet light when excited to luminescence by an elec. discharge between the electrodes, the container consisting of two glass layers fused to each other, the inner layer being thinner than the outer layer and consisting of an aluminate, hard glass inert to the vaporizable material having a softening temp. of about 700° and which transmits ultraviolet rays at a wave length of 280 millimicrons and longer and which is opaque to ultraviolet rays of shorter wave length, the outer layer consisting of a borosilicate glass having a softening temp. of about 550° and which transmits ultraviolet rays at a wave length of 280 mμ and longer and ultraviolet rays of shorter wave length and which is deleteriously affected by the rays of shorter wave length.

Electric gaseous discharge devices suitable for use as a light source. Willem Elenbaas (to General Elec. Co.) U. S. 2,177,694, Oct. 31. An elec. gaseous discharge device comprises a sealed tubular envelope having a pair of main operating electrodes sealed into its opposite ends, an auxiliary electrode sealed into the envelope adjacent one of the main electrodes, Hg within the envelope in an amt. sufficient to produce a pressure of about one atm. when

wholly vaporized, and a gaseous filling of Ne mixed with 0.2% of A at a pressure of about 3 mm.

Electric discharge device suitable for use as a light source. Ernst Friederich (to General Elec. Co.). U. S. 2,177,705, Oct. 31. A sealed vitreous envelope contains an anode, a source of electrons such as BaO, and a material which emits light under bombardment by the electrons emitted, one surface of the anode consisting of an electrically conductive oxide which may be ZnO or Cb_2O_5, and the light-emitting material, which may be Ca tungstate, being interposed between the electron source and the oxide.

Gaseous electric discharge arc lamp. Willem Elenbaas (to General Elec. Co.). U. S. 2,177,695, Oct. 31. Within a hermetically sealed envelope are placed a gaseous elec. discharge lamp device and a series ballast means for the device consisting of an incandescent filament, and a resistance having a high negative temp. coeff. of elec. resistance, connected in series with the lamp device and filament in the envelope, to maintain the temp. of the filament substantially const. during the starting and operation of the lamp device.

Gaseous electric discharge lamp device suitable for use as a light source. Hans Ewest (to General Elec. Co.). U. S. 2,177,696, Oct. 31. A gaseous elec. discharge lamp device of the high-pressure type comprises a container which may be formed of quartz or glass together with thermionic electrodes sealed in the container, a gaseous atm. such as one of A and Hg in the container, and a refractory metal body such as a sphere of W or Ta carbide mounted in heat-receiving relation to the arc-discharge path between the electrodes, means to supply elec. energy to the refractory metal body, and means to control the temp. and the light output of such body.

Electric lamp. Alfred Rüttenauer (to General Elec. Co.). U. S. 2,176,151, Oct. 17. A lamp is described which comprises an elec. gaseous discharge device contg. Hg and having a coating of luminescent material exposed to the radiations therefrom, the material comprising a mixt. of substantially equal amts. of Cd silicate activated with 0.8% Mn and Zn Be silicate activated with 0.5 to 1.5% Mn in which the Zn and Be are present in equal mol. proportions, whereby the light produced by the lamp is a warm white having substantially the same high luminous efficiency as that of the Zn Be silicate alone.

High-pressure metal-vapor electric discharge lamp. Victor J. Francis. U. S. 2,177,702, Oct. 31. Spaced, flexible electrodes which may be formed of W, etc., are used with a gaseous filling such as Hg vapor, etc. (various structural details being described). U. S. 2,177,703 relates to a thermionic cathode adapted for use within an elec. gaseous discharge device, and comprising a porous body of metal such as W wire helixes the pores or interstices of which are filled with thermionically active material, the porous body being surrounded by a helix of refractory metal, with a lead extending from one end of the helix through the porous body in good thermal contact with it (the helix being spaced from the porous metal body). U. S. 2,177,704 relates to various structural, elec. and operative details of a high-pressure metal-vapor discharge device. Cf. *C. A.* **34**, 3342.

5—PHOTOGRAPHY

E. R. BULLOCK

A physicochemical tone-separation process for photography. Hans Zickendraht, Jr. *Helv. Chim. Acta* **22**, 1001-22(1939); cf. *C. A.* **32**, 48915.—Based on the two known facts, that (*a*) the emulsion of a light-sensitive paper is capable of being impressed by brightness values of a range which is considerably greater than can be reproduced when the paper is viewed by reflected light, and that (*b*) bleach baths exist which dissolve Ag but do not attack Ag_2S, a new chem. tone-sepn. process has been developed. In this process, under continuous visual inspection, the gradation curve of a prepd. photographic image can be altered, as desired, within wide limits. The mode of action of the various bleach and toning baths which are needed for the process has been investigated, and explained and classified in a new theory. It is shown by examples how the artistic claims of a picture can be realized through appropriate variations of the process. Finally, the theory and the explanation of the process have been established by photomicrographs, and a new microsensitometric method is given for investigation of the grain distribution in depth in the emulsion layer. Author

Silver in the photographic process. Karl Schaum. *Kolloid-Z.* **89**, 211-14(1939).—A discussion. A. O. A.

Bromoil. René Lamarre. *Rev. franç. phot. cinémat.* 19, 79-81(1938); *Phot. Abstracts* **19**, 49.—Expts. are described to det. the optimal conditions of development, bleaching and inking in the bromoil process. Formulas and working instructions are given.

Change in gradation by nucleus denudation. Lüppo-Cramer. *Phot. Ind.* **37**, 130-1(1939); cf. *C. A.* **33**, 5137.—The effects of bathing exposed high-speed plates in a 0.01% hypo soln. before developing with $K_3Fe(C_2O_4)_2$, or in a 0.01% KI soln. before developing with heavily bromided hydroquinone, are illustrated by spectrograms. In the former expt. the virtual speed is increased and the gradation softened, with a little fog, while in the latter there is merely an acceleration of the early stages of development. L.-C. calls attention to the appreciable difference in meaning which he intends to convey by the expressions "nucleus denudation" and "nucleus isolation"; the latter refers to the nuclei in the interior of the grains.
E. R. Bullock

Spontaneous alteration of the latent photographic image. F. Urbach and A. Wolinski. *Sitzber. Akad. Wiss. Wien, Math.-naturw. Klasse*, Abt. IIa, **147**, 29-36(1938).—Some emulsions give a higher d. if development does not follow exposure immediately; this suggests a change in the latent image with time. In the present paper, U. and W. consider and use, as a method of indicating very small changes of the latent image, the intermediate Herschel effect (*C. A.* **23**, 2112), which they had encountered in their own expts.: a difference of d. resulting from 2 ways of applying red light—either simultaneously with, or after, the white exposure. They present a simple calcn. showing that the d. should be higher in the former case—based on the assumption that the differential decrease in d. is proportional to the duration of the red exposure and independent of the time, relative to the white exposure, at which it is applied. The expt. evidence, however, does not support this assumption, since the d. is definitely higher in the case of succeeding exposure. This indicates a change of stability with time of the latent image, and subsequent expts. show that the stability is increasing rapidly at first, and still slowly increasing after 22 hrs.; the decrease in d. by red exposure is shown to be proportional to the logarithm of the time elapsed after the white exposure. U. and W. were not able to find any connection between the change in stability of the latent image and the change of the latent image mentioned at the beginning, for this phenomenon was practically absent in the emulsions used in this investigation. G. Kornfeld

Image tones by development. Bertrand L. Twinn. *Photo Art Monthly* **7**, 321-7(1939).—A review of methods of direct and indirect toning. E. R. B.

Print toning by dye-coupling. Robert Ballentine. *Photo Art Monthly* **6**, 369-70, 375(1938).—A review, and description of a particular method. E. R. B.

Mechanism of development. II. Development by hydroquinone. T. H. James. *J. Phys. Chem.* **44**, 42-57 (1940); cf. *C. A.* **33**, 61792.—The rate of development by hydroquinone in the absence of Na_2SO_3 and O_2 varies as the sq. root of the hydroquinone concn. and the 1st power of the OH^- concn. in the pH range 8.0-8.9. The rates measured approximate the av. rates of development of the

individual AgBr grains. The addn. of quinone to the developer results in an increase in the development rate, which is due to an effect, presumably of a decompn. product of the quinone, upon the double-layer elec. barrier. The quinone likewise attacks the development centers, resulting in a decrease in the no. of developed grains for a given exposure. The bivalent ion is the active developing agent. Reduction occurs heterogeneously at the Ag-Ag halide interface. Comparative rates are given for the development reaction, autoxidation, and the Ag-catalyzed reaction of Ag ion with a series of substituted hydroquinones. Author

The action of corpuscular rays on the photographic emulsion. H. Wambacher. *Z. wiss. Phot.* **38**, 38–68(1939); cf. *C. A.* **33**, 2798⁴.—A review and bibliography (of about 70 references) are given of the photographic action of corpuscular rays, i. e., electrons, ions, protons, deuterons, etc. C. H. Evans

Direct traces of corpuscular rays in the photographic layer as a method of measurement in nuclear physics. I. General survey. E. Schopper. *Z. angew. Phot.* **1**, 21–8 (1939); cf. *C. A.* **33**, 3680¹. - The general phys. requirements for photographic registration of corpuscular rays are treated, and the possibilities of this method are shown by several examples. Special plates obtained from Agfa proved to be valuable in the application of this method, since, without pretreatment, they were microscopically free from fog. C. H. Evans

The direct photochemical bleaching of photoiodides. Luppo-Cramer. *Phot. Korr.* **75**, 129–32(1939); cf. *C. A.* **34**, 335¹.—Plates coated with a gelatino-iodide emulsion prepd. with a slight excess of KI, and soaked in a 2% $K_2S_2O_8$ soln. for 2 min. and dried, are first exposed uniformly to bright daylight until the emulsion acquires a gray-violet coloration, when they are washed in running H_2O for 1 hr. and dried, and then reëxposed to daylight behind an Eder-Hecht tablet. In a given time, bleaching of the print-out effect is seen to be appreciably more extensive than with a correspondingly prepd. and treated bromide emulsion. The gray-violet Ag photoiodide reassumes, in the more heavily exposed area, the pure yellowish white color of AgI and, on fixing, is glass-clear while the margin is brown-orange. There is appreciable yellow and red sensitivity, and the deposit under these particular tablet strips is, when fixed, not gray but reddish. These, and related, facts (such as the bleach-sensitizing and color effects of bathing the insolated iodide plates, after washing, in a 2% KBr soln. before exposing behind the tablet), and their possible explanation, are discussed. E. R. B.

A peculiar sensitization. Luppo-Cramer. *Phot. Korr.* **75**, 132–4(1939); cf. *C. A.* **30**, 4415² and preceding abstr.—An insolated AgI gelatin emulsion plate, after being "desilvered" with CrO_3 mixt., shows appreciably higher threshold speed (18° E.-H.) and greater contrast, on development in alk. amidol, than does a similar but uninsolated AgI plate, either treated with CrO_3 or not so treated. That this can be attributed to the sensitizing action of (persistently) adsorbed Ag ions is supported by the observation that a $AgNO_3$ treatment consisting of bathing the iodide plates in a 1% soln. for 3 min. is as effective as insolation. E. R. Bullock

Sensitization and desensitization of sensitive layers for high-energy rays. E. Schopper. *Phot. Ind.* **36**, 845 (1938); cf. *C. A.* **32**, 39²; **33**, 2829¹.—Optical sensitizers act very inefficiently or not at all for high-energy quanta such as x-rays, γ-rays or for corpuscular rays such as α-rays, protons or electrons. A new sensitizing action of pinakryptol yellow is described. Plates treated with this dye and exposed to β-rays *in vacuo* show a higher d. of developed grains along the tracks of these particles in the sensitive layer. W. F. Berg

Desensitization. R. Namias. *Progresso fot.* **45**, 331–5 (1938); *Phot. Abstracts* **19**, 39(1939).—Plates desensitized with pinakryptol green (I), but not with safranine (II), give an objectionable fog in caustic developers. A mixt. of a smaller amt. of I and more of II gives satisfactory results.

Mechanical properties of films. P. V. Kozlov. *Kino-Foto-Khim. Prom.* **1938**, No. 9, 28–32; *Khim. Referat. Zhur.* **2**, No. 3, 130; cf. *C. A.* **33**, 8513⁹.—There are 3 different regions on the stretching curve of films prepd. from cellulose ethers. The region of elastic deformation is most important for the motion-picture industry. This region of the stretching curve depends on the magnitude of the intermol. adherence of the cellulose ether complexes and, consequently, on the distance between the single chains or their regions, and on the nature of the cellulose ether. The region of plastic deformation (i. e., the sliding of the single chains in the film or their regions in relation to each other) is greater the greater the contact surface and the distance between them. The longer the chain, the greater is the possible contact surface and the greater is the work done in sliding of one chain in relation to another. The region of elastic deformation of the films with the oriented cellulose ether complexes (in the process of plastic stretching) is of secondary importance and is characterized as a "reserve" of durability. For best results the films must possess max. elastic and plastic deformability. W. R. Henn

Changes in the physicochemical properties of cinematographic films on prolonged standing. S. M. Solov'ev and Va. A. Shnaĭdman. *Kino-Foto.-Khim. Prom.* **1938**, No. 6, 54–6; *Khim. Referat. Zhur.* **2**, No. 3, 129–30; cf. *C. A.* **32**, 2855⁷.—There was but slight difference in the physicochem properties of emulsion-coated (unprocessed) and non-coated films which were stored outdoors for 6–7 years from those not exposed to the weather. Strength decreases with increased duration of storing. Aging under thermostatic conditions had the same effect on the dynamic properties as had natural aging. A splitting of the films into layers was observed in natural aging under unfavorable atm. conditions. W. R. Henn

Medium-speed single-layer films and exposure latitude. H. Starke. *Fot. Rundschau* **76**, 312(1939).—It has been found that a certain com. single-layer film of 17/10° DIN possesses sufficient latitude to give acceptable prints of a subject of normal lighting range, exposed from 0.004 to 4 sec. R. W. Henn

Photographic plates used in astronomy. M. G. Fracastoro. *Osservazioni e mem. R. osservatorio astrofisico Arcetri Univ. Firenze* No. **57**, 57–67(1939).—Data are presented of a new panchromatic emulsion (Ferrania Suiperpavero antihalo 20/10° DIN), which is being produced in Italy and which is highly sensitized for astronomical use. Microdensitometer curves of d. plotted against wave length show a smoother curve for the new emulsion as compared with the commonly used Agfa Isopan ISS, which has more pronounced peaks and depressions, especially in the red region of the spectrum. These peaks and depressions are further analyzed by curves comparing the new emulsion with the older types under different conditions of exposure at the various wave lengths at which the maxima and minima occur. C. R. Amadeo

Evaluation of motion-picture films by semimicro testing. J. E. Gibson and C. G. Weber. *J. Soc. Motion Picture Engrs.* **32**, 105–9(1939); cf. *C. A.* **33**, 4145³.—The article shows how the approx. quality and condition of film stored as permanent records can be detd. by tests for acidity, viscosity and residual $Na_2S_2O_3$; specimens weighing only 7 mg. each were used. These tests are recommended to archivists and librarians for detg. the condition of films in their custody, so that the necessity for making duplicates can be detd. before damage by deterioration is serious enough to be visible. J. G. Streiffert

Preparation of "magic photographs." Felix Formstecher. *Phot. Ind.* **36**, 1014–15(1938); *Phot. Abstracts* **19**, 78.—A review of the methods used for the prepn. of "magic photographs," i. e., bleached images on paper made visible by the action of some chemical or of light.

Methods of producing patterns on cloth (Freytag) **25.** Methods for prepn. of starting substances for sensitizers of quinoline series—isocyanines (Alekseeva) **10.**

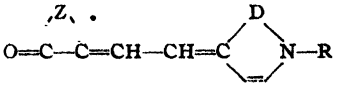
Color photography. Lothar Jakob and Bruno Wendt

(to Agfa Ansco Corp.). U. S. 2,177,257, Oct. 24. A process of producing colored photographic pictures comprises exposing to light a photographic material provided with at least one emulsion layer contg. a light-sensitive Ag halide, transforming the latent image into a Ag halide image, converting the Ag halide image by an amine capable of being diazotized or an antidiazotate thereof, the compd. contg. a mercapto group, an ethinyl group or an imino group, the H atom of the group being capable of being exchanged for a metal, into an image of the corresponding org. Ag compd. and transforming the image into an azo-dye picture.

Color photography. Edwin B. Hesser and Eva L. V. Hesser (to Photocolor Corp. of America). U. S. 2,177,342, Oct. 24. A method of producing a multicolor photographic record involves exposing from the same side 2 regions of photographic film having 2 sensitive layers arranged in superposition, the first layer nearest the lens being sensitive to blue and green but not to red, the second layer being effectively sensitive to red only, one region only being exposed through a yellow filter for recording a portion of the spectrum in the first layer and another portion of the spectrum in the second layer, and the other region being exposed without any filter for recording another portion of the spectrum in the second layer of such other region.

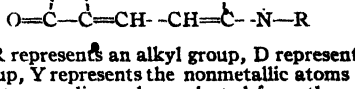
Color photography. Ernst Bauer (to Agfa Ansco Corp.). U. S. 2,177,632, Oct. 31. Color photographs are produced by a process which involves exposing to light controlled by an object to be reproduced, a 3-layer photographic element, two layers of the element comprising a color-forming development component fast to diffusion for the blue and the red picture, resp., and one layer comprising a substantive azo dye component; developing the element with an aromatic amino developer, thereby forming a Ag and a color picture in the two first-named layers in a single development step, and a Ag picture in the second-named layer, removing the undeveloped Ag salt, converting the residual Ag picture into a Ag antidiazotate picture and causing the substantive azo-dye component to couple with the silver-antidiazotate.

Color photography. Veracol Film Syndicate Ltd. and Humphrey Desmond Murray. Brit. 507,611, June 19, 1939. A light-sensitive Ag salt emulsion is developed by means of an aromatic amino developing agent and contains as a color-former a compd. of formula $X.CH_2.CH(CH_2COCH_2CONRR')_2$, wherein X is an O or a S atom, R is H or an alkyl, e. g., Me, Et, Pr or higher alkyl, aralkyl e. g., benzyl, alicyclic, e. g., cyclohexyl, aryl, e. g., Ph, or azole, e. g., benzothiazole, group and R′ is also a H atom or 1 of the above groups. R and R′ may be substituted with halogen atoms or OH, alkoxy, NO_2, NH_2, substituted NH_2, Bz or phenylazo groups. Color-formers specified are furoylacetamide and the *N*-furoylacetyl derivs. of the following: monoamines and their halo and NO_2 derivs., e. g., $PhNH_2$, *p*-nitroaniline, *p*-chloroaniline, 2,5-dichloroaniline, *C*-alkylanilines and their halo and NO_2 derivs., e. g., *m*- and *p*-toluidine, 2,5-dimethylaniline, 2,3,5,6-tetramethylaniline, *C*-alkoxy and *C*-aryloxyanilines and their halo and NO_2 derivs., e. g., anisidines, phenetidines, [illegible]-phenoxyaniline, di- and poly-[illegible]diamine, benzidine and bi-anisidine, α- and β-naphthylamine, *p*-aminophenylmorpholine, 2-amino-6-methylbenzothiazole and *p*-amino-*p*′-hydroxyazobenzene. Similar thiophene derivs. may be used. Developing agents specified are alkylphenylenediamines, e. g., dimethyl- and diethyl-*p*-phenylenediamines, and their derivs., alkyltolylenediamines and alkylnaphthylenediamines.



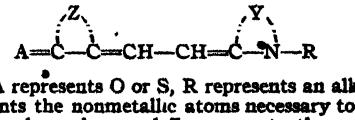
Photomechanical color process. John A. C. Yule (to Eastman Kodak Co.). U. S. 2,176,518, Oct. 17. In a photomech. process employing 3 subtractive-color coloring materials for the reproduction of a multicolored original, a method of making a color printer comprises exposing a sensitive photographic layer to one of the primary colors from the original and to a different color from the original, developing the layer, prepg. a positive image corresponding to a color from the original effectively the same as the different color, making a negative comprising the developed layer masked by the positive and printing a positive printer therefrom. Cf. *C. A.* **33**, 7226[1].

Coloring photographic images. Wm. H. Evans. U. S. 2,176,585, Oct. 17. A process of coloring a photographic image involves developing a light-exposed Ag halide type photographic emulsion, treating it without fixing in a bath which simultaneously removes the reduced Ag image and forms a latent non-Ag image capable of becoming a color image when treated with acid dyes of the type which are nondyeing to gelatin in the presence of an alkali, in the presence of an activator for the dyes such as NaOAc, removing the Ag salts in a fixing bath, and then staining the latent image with a soln. contg. NaOAc and an acid dye of the type mentioned.



Color correction of negatives and printing plates. Wm. J. Wilkinson (50% to Miehle Printing Press and Mfg. Co.). U. S. 2,177,195, Oct. 24. A process is employed which involves making: (*a*) yellow, red and blue color-sepn. photographic negatives of a multicolor subject, (*b*) a positive photographic transparency through the yellow-sepn. negative, (*c*) a corrective photographic overlay-transparency for the yellow-sepn. negative comprising making a photographic transparency through the positive transparency and the red-sepn. negative while the two are in superposed registered relation, (*d*) correction of the yellow-sepn. negative by applying the overlay thereto and in register therewith, (*e*) a second positive photographic transparency through the red-sepn. negative, (*f*) a corrective photographic overlay-transparency for the red-sepn. negative through the second positive transparency and the blue-sepn. negative while the two are in superposed registered relation, (*g*) correction of the red-sepn. negative by applying its corrective overlay thereto and in register therewith, and (*h*) corresponding printing plates from the corrected yellow-sepn. and red-sepn. negatives and the blue-sepn. negative.

Specially sensitized photographic emulsions. Burt H. Carroll and Edward P. Davey (to Eastman Kodak Co.). U. S. 2,177,635, Oct. 31. See Can. 380,343 (*C. A.* **33**, 5308[2]).



Photographic sensitizing dyes. Leslie G. S. Brooker (to Eastman Kodak Co.). U. S. 2,170,803, Aug. 29. Numerous examples are given of the production of merocyanine dyes of the general formulas

and

wherein R represents an alkyl group, D represents a phenylene group, Y represents the nonmetallic atoms necessary to complete a cyclic nucleus selected from the group consisting of 5- or 6-membered heterocyclic nucleus and Z represents the nonmetallic atoms necessary to complete a rhodanine nucleus. E. g., 5-(1-ethyl-2-quinolylidene)-3-phenylrhodanine is produced by refluxing 3-phenylrhodanine with 2-iodoquinoline ethiodide and triethylamine and abs. EtOH. U. S. 2,170,804 relates to the production of 5-(2-ethyl-1-benzoxazolylideneethylidene)rhodanine, 3-ethyl-5-(2-ethyl-1-benzoxazolylideneethylidene) rhodanine and various dyes of the general formula

wherein A represents O or S, R represents an alkyl group, Y represents the nonmetallic atoms necessary to complete a benzoxazole nucleus and Z represents the nonmetallic atoms necessary to complete a five-membered heterocyclic nucleus containing a nuclear N and a nuclear S atom, by a

individual AgBr grains. The addn. of quinone to the developer results in an increase in the development rate, which is due to an effect, presumably of a decompn. product of the quinone, upon the double-layer elec. barrier. The quinone likewise attacks the development centers, resulting in a decrease in the no. of developed grains for a given exposure. The bivalent ion is the active developing agent. Reduction occurs heterogeneously at the Ag-Ag halide interface. Comparative rates are given for the development reaction, autoxidation, and the Ag-catalyzed reaction of Ag ion with a series of substituted hydroquinones. Author

The action of corpuscular rays on the photographic emulsion. H. Wambacher. *Z. wiss. Phot.* **38**, 38-68(1939); cf. *C. A.* **33**, 2798[4].—A review and bibliography (of about 70 references) are given of the photographic action of corpuscular rays, i. e., electrons, ions, protons, deuterons, etc. C. H. Evans

Direct traces of corpuscular rays in the photographic layer as a method of measurement in nuclear physics. I. General survey. E. Schopper. *Z. angew. Phot.* **1**, 21-8 (1939); cf. *C. A.* **33**, 3680[1].—The general phys. requirements for photographic registration of corpuscular rays are treated, and the possibilities of this method are shown by several examples. Special plates obtained from Agfa proved to be valuable in the application of this method, since, without pretreatment, they were microscopically free from fog. C. H. Evans

The direct photochemical bleaching of photoiodides. Luppo-Cramer. *Phot. Korr.* **75**, 129-32(1939); cf. *C. A.* **34**, 335[1].—Plates coated with a gelatino-iodide emulsion prepd. with a slight excess of KI, and soaked in a 2% $K_2S_2O_5$ soln. for 2 min. and dried, are first exposed uniformly to bright daylight until the emulsion acquires a gray-violet coloration, when they are washed in running H_2O for 1 hr. and dried, and then reexposed to daylight behind an Eder-Hecht tablet. In a given time, bleaching of the print-out effect is seen to be appreciably more extensive than with a correspondingly prepd. and treated bromide emulsion. The gray-violet Ag photoiodide reassumes, in the more heavily exposed area, the pure yellowish white color of AgI and, on fixing, is glass-clear while the margin is brown-orange. There is appreciable yellow and red sensitivity, and the deposit under these particular tablet strips is, when fixed, not gray but reddish. These, and related, facts (such as the bleach-sensitizing and color effects of bathing the insolated iodide plates, after washing, in a 2% KBr soln. before exposing behind the tablet), and their possible explanation, are discussed. E. R. B.
